
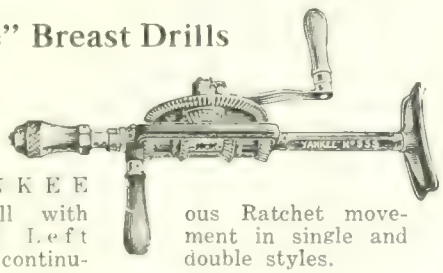
Carried in stock sizes from ONE INCH up, both in thousands and in ten thousands; also Inchanics' Tools, as well as a complete assortment of other lines.

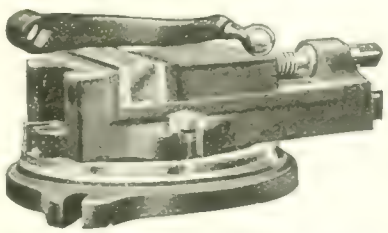
### "Yankee" Breast Drills



in stock at all times. We have the YANKEE Breast Drill with Right and Left Hand and continuous Ratchet movement in single and double styles.

### "Universal" Combination Pliers

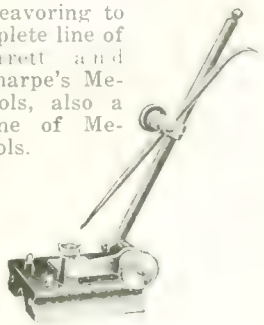
Forged of High Grade Tool Steel perfectly tempered and carefully machined. Consists of Screw Driver, Reamer, Flat Nose Plier, Pipe Wrench, Wire Cutter, etc.



**"Williams" Combined Stationary** and Swivel Milling Machine Vise, with removable jaws. Depth of Jaw 1⅜". Width of jaw 5". Vise opens 3". Weight 45 lbs. List price, $25.00.

### MECHANICS' TOOLS

We are endeavoring to carry a complete line of both Starrett and Brown & Sharpe's Mechanics' Tools, also a complete line of Mechanics' Tools.



### "Yankee Screw Drivers

they are strong, durable, well-balanced tools. The fastening of blade and handle is such that they cannot be loosened in use, or even usual abuse.

### "Yankee" Hand Drills

These Tools are built mechanically on lines of a Tool rather than as a piece of Hardware. They are strong and substantially built for hard work and durability.

### Trahern Pumps

For water, Oils and Cutting Compound The most RELIABLE Pump at the most REASONABLE Price. Buy the Pump with a reputation behind it. We have them right in stock.

**Complete line of TRANSMISSION EQUIPMENT, POWER HOUSE, MILL and FACTORY SUPPLIES always in stock.**

## WM. NEWMAN JOINS THE U. S. FLEET CORPORATION

**Well Known Toronto Architect Takes Responsible Position on War Work**

With the reorganization of the plant of the United States Fleet Corporation at Hog Island, Philadelphia, the largest shipbuilding company in the United

WILLIAM NEWMAN

Naval architect and works manager of the Polson Iron Works, Toronto, who has left that company to join the United States Fleet Corporation.

States, Toronto loses Wm. Newman, naval architect and works manager of the Polson Iron Works & Steel Shipbuilding Company, who will in the course of a few days become connected with the American company.

"I am leaving for the coast in a few days," said Mr. Newman, "but the chances are that I will remain in the East when I make my final decision as to where I will locate myself."

### Given a Purse of Gold

Upon severing his connection with the Polson Company, Mr. Newman was made the recipient of a handsome purse of gold presented by Col. J. B. Miller on behalf of the company.

---

that much additional attention to this work."—G. S. Capwell, Sec.-Treas.

The Brown, Boggs Co., Ltd., Hamilton. —"As far as our works are concerned there is no apparent difference and the extra hour in the evening is certainly very enjoyable and appreciated."—W. E. Blandford, Sec.-Treas.

### In Montreal Shops

Mr. Mead of the Canadian Vickers Co. says that the change was effected with very little trouble and no noticeable difference was apparent on Monday morning when about 2,500 men started to work an hour earlier (by daylight) than they had done two days before. He could not see how any serious objection could be made to such a move even under normal conditions.

Lymburners Limited are working 24 hours every day, three shifts of eight hours each, and very little difference was noticed on the Monday of the change, one of the Sunday shifts working an hour less to avoid confusion on the appearance of the following shift. Mr. F. McDonald, the production engineer, intimated that the change was made effective without the least trouble.

Mr. McCleery, superintendent of the John McDougal Caledonia Iron Works, said that the daylight saving was put into force without much difficulty, but intimated that while the men would have an additional hour of daylight in the evening to their own account, it would have little effect on the saving of light to the plant as for the hour in the morning they would require to use the light that was saved during the closing hour.

As many of the factories in this vicinity have organized recreation clubs the men are very well pleased with the recent change as it enables them to have the additional hour for their sports. Considerable interest is being shown in the cultivation of spare lots about Montreal and many factory employees and also those of the office staffs have accepted the daylight saving with satisfaction, realizing that they will have much more time for home gardening.

## TUNGSTEN ORE DISCOVERED IN MANITOBA

SCHEELITE has been found in the Falcon Lake district, Manitoba, near the molybdenite deposits discovered last fall. This tungsten ore was found by a prospector who had attended the evening classes for prospectors at the University of Manitoba. The ore was brought to the instructor, Mr. J. S. DeLury, by Mr. J. MacMillan and was identified as scheelite. It is noteworthy that the molybdenite discovery last fall was also made by a prospector who attended the evening classes at the university.

## RECLAIMING WASTE

A CORRESPONDENT in the "Practical Engineer" states that the high cost of waste and rags used throughout the machine shop makes it necessary to cast about for means to reduce charges for this material, so there was devised a washing arrangement, which was made up of some old pipe fittings. A piece of 12-in. pipe was arranged with companion flanges on each end, a steam inlet in the side, and a drain at the bottom. A screen was then placed in the pipe about 4 in. above the steam inlet. The oil waste was placed in the washer above the screen by removing the companion flange, and then the whole mass was boiled by turning in the live steam, the condensation dripping down through the waste and carrying the oil and dirt off through the blow-off valve. While this crude washing did not turn out perfectly clean waste, it nevertheless, took out such a large percentage of the oil, grit and dirt that the waste could be used for practically all purposes. The expenditure for new waste was thereby cut down by one-half to one-third each month.

## NOW GETS POSITION OF GENERAL SUPT.

**R. M. McCleery Was Designer for the Caledonia Iron Works**

**R. M. McCleery,** who for the past several years has been holding the position of chief draughtsman and designer for the John McDougall Caledonia Iron

R. M. McCLEERY

Works, has been promoted to the position of general superintendent. Mr. McCleery has had a wide and varied experience in general engineering and marine work.

---

YOUTH is not a time of life; it is a state of mind. It is not a matter of ripe cheeks, red lips and supple knees; it is a temper of the will, a quality of the imagination, a vigor of the emotions. It is the freshness of the deep springs of life. Youth means a temperamental predominence of courage over timidity, of the appetite for adventure over the love of ease. This often exists in a man of fifty more than in a boy of twenty. Nobody grows old by merely living a number of years. People grow old by deserting their ideals. Years wrinkle the skin, but to give up enthusiasm wrinkles the soul. Worry, doubt, self-distrust, fear and despair—these are the long, long years that bow the heart and turn the greening spirit back to dust.

Whether sixty or sixteen, there is in every human being's heart the lure of wonder, the sweet amazement of the stars and at star-like things and thoughts, the undaunted challenge of events, the unfailing childlike appetite for what next, and the joy of the game of living.—American Iron and Steel Institute Bulletin.

# INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## MUNICIPAL

**Chatham.** The water commissioners of Chatham have decided to instal two additional filters at the filtration plant.

## TENDERS

Sealed tenders will be received until 4 p.m., on Monday, April 29, 1918, for the construction of a breakwater at Margaree, Inverness County, N.S. Plans and forms of contract can be seen and specification and forms of tender obtained at this Department and at the offices of the District Engineers at Halifax, N.S.; North Sydney, N.S., and on application to the Postmaster at Margaree, N.S.

**Ottawa.**—Sealed tenders addressed to the undersigned and marked "Tender for Dredge No. 114, or Tug St. Paul," etc., as the case may be, will be received until 4 p.m., Thursday, May 2, 1918, for the purchase of Dredge P.W.D. "No. 114," Tug "St. Paul," Dump Scow No. 50, Dump Scow No. 32, Dump Scow No. 33, lying afloat in Burlington Bay, Hamilton, Ontario, near the International Harvester Co. dock. Tenders may be submitted for any one of the above items or plant, or for all the plant.

Dredge P. W. D. "No. 114": wooden hull, 25 ft. beam, 75 ft. long, 7ft. 6 in. depth, in poor condition; locomotive boiler about 100 lb. pressure, 4 ft. 2 in. diameter, 16 ft. 2 in. long. Engine single 14 in. x 16 in. Tug "St. Paul"; wooden hull 52 ft. x 16 ft. x 9 ft. draft; engine 12 in. and 24 in. x 18 in.; boiler Fitzgibbon type 6 ft. x 7 ft. x 12 ft. pressure about 130 lbs. Tug in fair condition. Scow No. 50; six pocket wooden hopper scow, capacity about 460 cubic yards. 132 ft. long, 26 ft. 6 in. beam, 8 ft. 9 in. depth. In poor condition. Scow No. 32; two pocket wooden hopper scow, about 105 cubic yards capacity, 70 ft. long, 19 ft. 6 in. beam, 7 ft. 4 in. depth. In good condition. Scow No. 33: two pocket wooden hopper scow, about 105 cubic yards capacity, 70 ft. long, 19 ft. 6 in. beam, 7 ft. 4 in. depth. In good condition. Sale is subject to an upset price.—R. C. Desrochers, Secretary, Ottawa:

## PERSONAL

**Charles Watt**, who has successfully filled the position of general superintendent of the shell department of the Canada Stove and Foundry Company, of St. Laurent, P.Q., has resigned his position with the firm.

**Herbert Johnson**, who for the past six months has been Canadian sales agent for the Armstrong Whitworth Company of Canada, has been appointed to the position of general superintendent at the [illegible].

**Mr. William Newman**, architect of the Polson Iron Works, Toronto, was presented with a purse of gold by the company. The presentation was made by Col. J. B. Miller on behalf of the firm. Mr. Newman is leaving to accept a position in the United States.

## TRADE GOSSIP

**Will Spend Money.** The Winnipeg Electric announces the expenditure of $317,000 to increase its rolling stock.

**Peacock Brothers**, of Montreal, contemplate the erection of a plant for the manufacture of Weir feed water pumps for marine service.

**To Make Report.**—C. H. Kellogg from Oklahoma is in Medicine Hat to look over the Ansley mine. He believes there is a large body of coal there.

**Will Enlarge Plant.**—The British Forgings, Ltd., have been granted a permit by Toronto for an $80,000 addition to their forge shop, in the Ashbridge's Bay industrial area.

**Vancouver.**—The coast cities, Victoria, Vancouver and New Westminster, are "coming back," according to very reliable reports from the coast. Shipbuilding and other basic industries are causing the boom in trade. It is estimated that the population of Vancouver has been increased by 12,000 in the past year.

**Direct Advertising.**—The Wm. Kennedy and Sons, Ltd., of Collingwood, wanted men for their shell shop. They advertised, not in a condensed way, but four columns wide and abuot 3½ inches deep. Their appeal was made in the local papers. The real value of the advertising columns is becoming more and more recognized.

**Opened in Montreal.**—Charles P. Archibald and Company have recently opened an office at 164 St. James St., Montreal, to handle all classes of railway, marine and pulp mill supplies, together with all kinds of general machinery. Mr. Archibald, who is in charge of the sales, continues to represent the Ottawa Car Co., in addition to his new enterprise.

**To Vote on By-law.**—The ratepayers of Tillsonburg will vote on the 6th of May in regard to the contract between the city and the Huntley Mfg. Co., which recently suffered loss from fire, and which was considering offers to remove elsewhere. The town discharges the mortgage held against the plant, and pays over the insurance money and makes other concessions. The voting is to ratify the agreement.

**The Future of Steel.**—Nothing has yet come of the proposed merger between Nova Scotia Steel and Coal and Dominion Steel. Officials of the Nova Scotia Co. are not worried about a statement that has found circulation to the effect that they might find difficulty in maintaining their dividend in after-war markets. They rely on their pre-war record, and to the favorable developments following the opening at their Wabana property. The future of the steel business, the Scotia directors are satisfied, is not in jeopardy, but on the other hand faces a field full of splendid possibilities.

**New Brass Industry.**—Hamilton Brass Ltd., Burlington Street, E., Hamilton, Ont., has purchased a four acre tract at the west end of Main Street, near the C.P.R. round house, and ground is being broken for the erection of the first building, which will be about 30 by 120, one storey. It will be equipped with crushers, rolls, jig tables, pit furnaces, Swartz furnaces, assay laboratory, and all equipment necessary for the concentration and smelting of brass and copper, slag, ashes, sweepings, skimmings and scrap.

**Preston Shop Busy.**—There are at present some excellent prospects for business ahead of the Preston Car and Coach Company. The Toronto Street Railway Company are asking for figures on the hundred electric cars while the Dominion Government is about to place an order for nineteen baggage cars. Either order in its entirety will run to about a half million dollars. Both orders will be placed somewhere and the Car and Coach have every reason to believe they will secure a full share of the business. Other smaller orders are also in prospect one of which is nine cars for the York Radial. Then there is considerable repair work ahead for the same reason that new work is required.

**New Repair Shop.**—Peacock Brothers of Montreal have recently added a new branch to their other activities, that of a fully equipped repair department for handling the repairs of different kinds of recording instruments, such as various types of pressure gauges, thermometers, pyrometers, and other appliances requiring very accurate adjustment. The laboratory is being rapidly equipped for the efficient handling of this work. Mr. E. Dawson, who is in charge of this department, has had a wide experience in this class of work. Little effort has been made in the past to establish a repair bureau of this character here in Canada hitherto the bulk of this repair work has had to be sent to the States, entailing a heavy expense on custom charges.

**New Bridge Company.**—The T., H. & B., C.N.R., and N.Y.C. have formed a company under the name of the Canadian Niagara Bridge Company to build a new bridge over the Niagara River near Bridgeburg. The company has a private bill, which will come before the Dominion Parliament at the present session. The directors of the company are: Baron Shaughnessy of Montreal, president of the Canadian Pacific Railway; Alfred H. Smith of Chappaqua, N.Y., president of the New York Central and Michigan

W. H. BANFIELD & SONS
372 Pape Avenue, Toronto, Can.

Central Railways; John N. Beckley of Rochester, N.Y., president of the Toronto, Hamilton & Buffalo Railway; Edward Donaldson Cahill, K.C., of Hamilton, and William Percy Torrance of Toronto, barrister-at-law.

**A New Process.**—A highly important discovery has recently been made by H. V. Jansen, a chemical engineer, resident of Toronto, by which the whey from milk can be made into alcohol. Dr. J. F. Strangard of Toronto is associated with Mr. Jansen in the invention, patents for which have been taken out in all available countries. The discovery not only means the saving of immense quantities of grain now being used, but it cheapens the cost of alcohol to a very material extent. The patent has been disposed of for a cash consideration of $50,000 and a quarter interest in the formation of a parent company of $1,000,000. Mr. Jansen, the inventor, is to be retained by the company at a salary of $6,000 a year, and Dr. Strangard will be engaged to dispose of the patent rights in European countries. Both are Danes with several years' residence in Canada.

## MARINE

PORT COLBORNE.—The steamer Wyoming cleared here on the 17th for Buffalo dry-dock. There is no ice in sight.

**Toronto.**—It is expected that the steamer Cayuga, of the Canada Steamship Line, will go into commission on May 18th between Toronto, Niagara-on-the-Lake, Queenston, and Lewiston.

**Victoria.**—The C. P. R. steamers Empress of Asia and Empress of Russia have been commandeered by the Dominion Government. The order has already gone forth that the sailings of the ships have been cancelled.

**Newcastle, N.B.**—At the shipyard at Rosebank, the work on the vessel under construction is proceeding satisfactorily. This vessel is a four-masted schooner of 540 tons. It is expected that she will be launched about August 1st. The keel for another vessel is also partly laid.

**Halifax.**—The steamer City of Wilmington was burned south of Sable Island on Saturday. The fire broke out suddenly early in the morning, and, despite the efforts of the crew, it spread rapidly throughout the ship. "S.O.S." signals were flashed out and preparations were made to abandon the steamer. The weather was fairly favorable and the boats were launched, provisioned and the crew entered them.

**Cleveland.**—The steamer Harvester, ter, which left South Chicago for Port McNicoll with a cargo of oats, was the first boat of the grain fleet to sail, and she may have trouble making port, as it was reported early in the week that the ice in Georgian Bay is pretty heavy. The Harvester has 640,000 bushels of oats, which is the largest grain cargo ever loaded at a Lake Michigan port.

**Detroit.**—Built in 1879 and for many years considered one of the finest vessels on the Great Lakes, the side-wheeler passenger boat Idlewild was sold to-day to Texas parties, who will operate her in freight trade out of Texas ports. The boat has been out of commission ten years. She formerly ran between Detroit, Toledo and Port Huron, and later was placed on a St. Lawrence River route. The Idlewild is an iron hull vessel, 150 feet in length, 26 feet wide and 47.4 feet deep. She was constructed at the Wyandotte yards.

**Owen Sound.**—One of the oldest residents of Owen Sound section passed away recently in the person of Captain Alexander McKenzie, East Linton. For many years he has been known on the Great Lakes, where he has commanded many boats during his 54 years as a sailor in Canada. He was born in Rossshire, Scotland, 74 years ago, and came to Canada when 20 years of age, living first at Toronto. The late Capt. McKenzie was for many years in command of various schooners and was a sailor of the old school, one who felt for years that sailing on anything except a schooner was not sailing at all. He was a strict disciplinarian with his crews, but always commanded their respect.

## INCORPORATIONS

**Universal Coal Co., Ltd.,** has been incorporated, with capital of $100,000, to deal in and produce coal, wood and fuel of all kinds. Head office, Toronto. Directors: R. H. Parmenter, W. S. Morlock, and S. D. Fowler.

**The National Shoe Mfg. Co.** has been incorporated, with capital of $40,000, to manufacture and deal in boots, shoes, etc. Head office, Toronto, and provisional directors are : B. E. Bull, J. G. Shaw, and J. Montgomery.

**The Dyrob Steel Tools, Ltd.,** has been granted incorporation to forge, manufacture, etc., tool steel, iron, metals, etc. Capital is placed at $100,000. Head office, Toronto. Provisional directors: C. J. Baguley, T. Dunlop, S. McD. Robertson, and F. C. Dyer.

**Toronto Cabinet Co., Ltd.,** has been incorporated, with capital of $40,000, and head office in Toronto. The company can carry on business of makers and dealers in furniture, musical instruments, etc. Provisional directors: A. Whitehead, R. J. Smyth, and M. A. Gallagher.

### MARKET FOR PUMPS AND PUMPING MACHINERY IN SOUTH AFRICA

S. W. HONAKE, United States' vice-consul at Johannesburg, South Africa, reports as follows, in part, regarding the market for pumps in that country:

Pumps and pumping machinery are used principally to supply water to municipalities, to meet agricultural and rural needs, and to satisfy the requirements of the mining industry. As mining is the principal industry of both the Transvaal and Southern Rhodesia, the principal demand is in connection with it, and the equipment already in use is valued at millions of dollars and em-

braces the most modern and approved types.

**Types of Pumps Used**

Swiss, British and American pumps are used throughout this consular district. The most popular of the pumps manufactured in Switzerland is said to be the "Sulzer," while those imported from England are as follows: Climax, Tangye, Allen, Pulsometer, Pearn, Robeson-Davidson, Rees-Roturbo, etc. German pumping machinery has never been extensively used, but the "Hoppe" pump had a fairly large sale previous to the outbreak of war. However, it is said that the big pumping on the Rand is done chiefly with American machinery, working against heads of from 2,000 to 2,300 feet. Although the American plunger pump is stated to accomplish very good results, gradual inroads upon this system has been made by the high-lift centrifugal pump, which is manufactured both in the United States and on the Continent.

**Pumps Used in Mines and for Municipal Purposes**

Pumping conditions on the Rand are said to be about as severe as in any part of the world. The quantity of water pumped from the mines of the Witwatersrand is approximately 400,000 gallons per mile of reef. Pumps having the latest improvements have, therefore, been installed, and with some of these it is stated that it is possible to obtain an efficiency of 70 per cent. when raising fairly large quantities of water against a head of 4,000 feet in one lift.

It is stated by a large dealer that the average pump requires 500 gallons of water per hour up to 100,000 gallons for irrigation purposes.

For municipal purposes water is generally obtained from underground sources, as the surface-water supply systems are comparatively rare in view of the scarcity of lakes and rivers of importance near commercial or agricultural centres. In the case of the Witwatersrand, water is obtained partly from drilled wells and partly from shafts sunk in the dolomite formation. The Johannesburg municipality does not pump its own water, but obtains it from the Rand Water Board. The sale of water by this corporation amounted to 9,860,000 gallons a day for the period ended March 31, 1917. This is the largest quantity disposed of, the previous record being that of 9,637,000 gallons attained in 1913-14.

## QUADRUPLE "TUBE" SPEED

### Kearney Railway Claims Speed of 150 Miles Per Hour for Trains

The Kearney high-speed railway, so the inventor, Mr. E. W. Chalmers Kearney, told the Society of Engineers the other night, had now been satisfactorily worked out for speeds up to 150 miles an hour, and would come into use as soon after the war as was practicable. Future tube railways would provide effective speeds of from three to four times those of the present London tubes if the system was adopted. A recent improvement in the Kearney system was the design of a "stepless" street level station.

## INCREASING CANADA'S MINERAL PRODUCTION

THE discovery by chemists in the Forest [illegible] of the Interior that pine oil can be produced from Canadian trees is of great interest to metal mining companies in Canada because this oil is necessary for the carrying out of the celebrated oil flotation process for the extraction of ore. The supply of pine oil from the southern United States is so limited that it is practically all required for United States mines. The Forestry Branch chemists not only discovered how to make pine oil in Canada but they found that a by-product, creosote oil, of the hardwood distillation industry could take the place of the more expensive pine oil. This means much to the mining interests of Canada, and is another evidence of the Government's work to aid industry in increasing production to the highest possible point in war time.

## MAKING MORE NOW THAN BEFORE WAR

### What An Investigation of the Old Country Business Has Brought to Life

THE immense profits made by munition manufacturers of Britain, and even greater profits which they would have made had it not been for the supervision of their contracts, are disclosed in the report of the committee on national expenditure, issued recently.

The committee found that in the aggregate twenty-six firms selected at random have made profits five times greater than in normal times; others have made profits of 27 per cent. on the turnover, or 341 on their capital.

On the other hand, technical investigations have resulted in the saving of £3,000,000 on cordite contracts, more than £35,000,000 on gun ammunition, £2,000,000 on gun equipment, and £1,700,000 on aircraft.

## ACCEPT HUDSON MAXIM'S "NON-SINKABLE" DEVICE

### U.S. Shipping Board Officials Take it for Experimental Work

HUDSON MAXIM'S device for a non-sinkable ship has been accepted for experimental purposes by the shipping board which anounced that officials had decided some start should be made toward producing vessels that could not be sunk by submarines.

Out of thousands of methods suggested the Ship Protection Committee, headed by John A. Donald, has selected several for special for special tests, of which Mr. Maxim's will be the first.

As described by Mr. Maxim to a Senate committee, after the shipping board first made an unfavorable report on it, his device consists of a row of cylinders containing water placed around the interior of a vessel's hull. Back of the cylinders would be a steel screen. Explosion of a torpedo would atomize the water against the screen, the vapor dispersing the heat and absorbing the gases which cause the damage in an explosion.

## START BUILDING FROM THE BOTTOM

### So B. C. Men Will Urge That Making of Pig Iron Get First Consideration

THE initial objective of the British Columbia steel delegation when it meets with the Federal authorities at Ottawa during the next few weeks will be the establishment, first and foremost, of a pig iron plant, if the proposal put forward at last night's meeting of the Central Iron Committee is given effect. The building and operation of a pig plant, it is held, may be the thin end of the wedge that will eventually shape itself into the most prolific iron and steel industry on the continent.

Mr. Thomas Walker, of the Hafer Machine Works, Vancouver, made the suggestion that as a starter in getting the wheels of the steel business turning the delegation should urge, prior to any hint at the proposition of building rolling mills or steel plate works, the establishment of a pig iron plant. Such a plan, he declared, would be building from the bottom and not from the top. If the production of pig iron was given the principal consideration in the representations to Ottawa, there was a good chance that something definite might be done at an early date. If the other more advanced and costly projects were put forward the result of the agitation might prove negative.

## COSTLY MACHINE TO TURN OUT BRIQUETTES

### Hamilton City Council Finds Out Where It Can Spend $40,000

SOME time ago City Engineer Gray, of Hamilton, wrote to the Malcolmson Briqueting Co., of Chicago, seeking information regarding machines which might be used in event of the city undertaking to manufacture coal briquettes from A. Peart's recipe. This morning word was received that a suitable machine could be purchased for about $40,000, and that information regarding it was being forwarded. The Peart briquettes are made out of coal dust and mud, but it is doubtful if the city will be willing to spend $40,000 on a machine to experiment with them.

## ANTHRACITE BUYERS ARE LESS INSISTENT

### But the Demand is Still Well Ahead of the Available Supply

*The Coal Trade Journal* of Buffalo says: "The weather having moderated, the demand for anthracite is not quite so insistent, but it is still running ahead of the supply. The local trestles have

been getting more chestnut coal than any other size, with little stove coming occasionally. Some officials who have urged customers to get their coal in early would gratify those in receipt of this excellent advice if they would add a word as to where the coal could be procured. Dealers are way behind on orders and expect to be for some time. After the severe winter consumers are in a mood to put in coal as early as possible.

## MINERAL PRODUCTION IN QUEBEC

THE preliminary statement of the mineral production in the province of Quebec for the year 1917 issued by the Department of Colonization, Mines and Fisheries says:

The total value of the mineral production of the province of Quebec during 1917, as shown by the provisional compilation of returns received at the department, amounted to $16,051,188. This is an increase of $2,764,164, as compared with the previous year, or 20.8 per cent.

In the tables "building materials" have been kept separate from the "products of the mines." As in the three previous years, the building materials show a decrease, whereas the products of the mine show an increase of [illegible] per cent.

The following gives the total figures of the province for each year since 1900. It may be seen that in eighteen years the value of the mineral production of the province has grown from 2½ million dollars to 16 million dollars, a proportional increase of 540 per cent.

| | | | |
|---|---|---|---|
| 1900.... | $2,546,076 | 1909.... | $5,552,063 |
| 1901.... | 2,997,731 | 1910.... | 7,323,281 |
| 1902.... | 2,985,463 | 1911.... | 8,679,786 |
| 1903.... | 2,772,762 | 1912.... | 11,187,110 |
| 1904.... | 3,023,568 | 1913.... | 13,119,811 |
| 1905.... | 3,750,300 | 1914.... | 11,732,783 |
| 1906.... | 5,019,932 | 1915.... | 11,465,873 |
| 1907.... | 5,391,368 | 1916.... | 13,287,024 |
| 1908.... | 5,458,998 | 1917.... | 16,051,188 |

The mineral production of the province for 1917 is as follows:

| | Quantity. | Value. |
|---|---|---|
| Asbestos, tons .... | 137,242 | $7,198,558 |
| Asbestic, tons .... | 17,210 | 42,139 |

HOW to tell a GOOD File by the tang

First, understand what we mean by "good." For an ordinary file may, for a time, do fast work on soft material. A file, to be what we term a **good** file, however, must do fast work on the hardest, the toughest material, and continue to do it long after the teeth of a common file would be worn smooth. A file made of

Crucible Steel

is the only file able to retain sharp cutting teeth against hard metal.

Therefore, only a crucible steel file meets our idea of a good file.

There is but one line of files from 3 to 24 inches made absolutely of crucible steel, and they're backed by 50 years of file-making experience. You can tell them by this trade-mark on the tang.

## ALBERTA MINES INCREASE OUTPUT

ACCORDING to the figures for 1917, as compiled by J. T. Sterling, of the Mines Branch of the Department of Public Works, the total output of Alberta mines for the year was 4,863,414 tons, with 283 mines in operation. One copper mine was opened up on the main line of the C. P. R. west of Banff, and two shale mines are in operation at Red Cliff, near Medicine Hat. The total output of lignite coal for the year was 2,637,829 tons; of bituminous, 2,206,868 tons; anthracite, 118,718 tons; and briquettes, 93,818 tons. There were also 31,630 tons of coke burned. The total output for 1916 was: Lignite, 2,172,801 tons; bituminous, 2,335,259 tons; anthracite, 140,544 tons; briquettes, 107,959 tons; coke, 41,950 tons. This is the first time that the output of lignite has not been greater than the bituminous. It shows a considerable increase in lignite and bituminous and a falling off in anthracite, briquettes and coke. The total number of men employed in Alberta in the lignite field during the year 1917 was 5,779, as compared with 5,060 in 1916; in bituminous, 3,746, as compared with 3,234 in 1916; and in the anthracite, 287 for 1917 and 305 in 1916. The total number of men employed for the year was 9,812 in 1917 and 8,599 in 1916.

## MACHINERY BELTING FOR SOUTH AND CENTRAL AMERICA

THE London *Times* trade supplement says that the export trade of Great Britain in machinery belting—whether of leather, woven hair, or cotton—is of some importance is proved by the fact that our share of this industry is valued at something over £1,600,000 per annum. The German export trade of a similar nature has hitherto had a value of £700,000 or £800,000, while that of Austria-Hungary has amounted to a little over £23,000. The Latin-American countries, especially the larger States of Argentina, Brazil and Chile, and perhaps Mexico, are consumers of all classes of machinery belting, since they are always adding to their existing manufacturing plant. There are no belting manufactories of any consequence in any of these states. British-made belting is well known and very well thought of in Argentina and Brazil, and fairly largely used in Chile. To Argentina before the war we normally sold such goods to the value of a little over £25,000, to Brazil £33,000, and to Chile £9,500. The corresponding exports from Germany to these countries amounted to £8,700, £6,200, and £3,350. In regard to the export of woven hair belting, as well as of cotton belting, British manufactures enjoyed a wide popularitw. In 1913 we sold goods of this description to Argentina of a value of £24,700 (against Germany's £5,450); to Brazil £20,200 (against Germany's £650); and to Chile, £13,100 (against Germany's £8,450). It is, however, in the smaller Republics—Cuba, Bolivia, Uruguay, and the Central Americas—that the more serious German competition had hitherto been met with. It is here, therefore, that at the present time we have the better chance of extending our connection. Ordinarily Cuba took from Germany manufactures of this class four times in excess of British supplies. In 1913 Germany supplied machinery belting of woven hair or cotton worth £1,200, against our £300. Naturally the United States furnished more than the two together, but that was due to the advantageous geographical position occupied by our Transatlantic competitor. The reputation enjoyed in all foreign markets by British-made belting (raw hide is usually accepted in preference to the ordinary tanned leather; being stronger and much thinner) is very sound. Continuous woven leather belts of British make are to be found in many of the principal machine shops and railway shops of South America, while the patent laminated belting, made of a number of leather strands placed side by side on edge and then sown together, has also a market. The most serious competitor of the leather belting has been the Gandy belting, which is waterproofed and unaffected by a change of temperature. This class of belting is found peculiarly suitable for the South and Central American markets. Another class of manufacture for which there should be a demand is the belting made of several plies of canvas treated with gutta-percha and balata since it possesses considerable strength and is thoroughly waterproof. United States manufacturers have introduced an improved kind of belting made of American cotton canvas, cemented in layers by vulcanized india-rubber, and covered by a specially prepared compound of india-rubber, which is forced into the canvas while passing through the rolls of a special form of calendar. Belts of this description have a smooth, even surface, and are found very durable and unaffected by damp or exposure—valuable factors where much of the belting in South America is in open sheds or employed in underground damp atmospheres.

## AUSTRALIA'S MERCANTILE MARINE

D. H. ROSS, Canadian Trade Commissioner at Melbourne, reports that the Australian Prime Minister created considerable surprise in an announcement to the effect that the Commonwealth Government has placed orders for fourteen ships in the United States. The majority of these vessels are now under construction and some are nearing completion.

Since the war 121,192 tons of coastal

shipping has been withdrawn by periodical requisitioning by the Government for transport and other urgent Imperial work. The decision of the Government to replace at least a portion of this tonnage by American cargo carriers was quite unexpected.

It is stated that ten of the new fleet will be ordinary steamers, with a speed of nine to ten knots. They are being specially constructed for wheat transport and will have a deadweight tonnage of about 3,300 tons. Four of the vessels are to be fitted with Diesel oil engines and, theregore, can be classed as auxiliary ships.

Particulars have already appeared of the fifteen cargo steamers purchased in June, 1916, by the Commonwealth Government. This fleet, comprising 65,245 tons gross and 41,868 tons net register, has been actively employed at such remunerative rates that it is now estimated the net earnings have paid off the original outlay of approximately £2,000,000.

In addition, the Commonwealth Government's shipping department has controlled, since the beginning of the war, twenty-one steamers aggregating 108,419 tons gross register and five sailing vessels of 12,312 tons gross. One of the steamers has since been made available to the Government of India. This fleet of sailers has been augmented by the purchase of a large ship in Melbourne, which is now being refitted for oversea trade.

On delivery of the steamers and auxiliary vessels now under construction in the United States, the Government will be operating forty-five steamers, four oil-engined ships and six sailing vessels. This fleet will serve a most necessary purpose for the transfer of Australian produce oversea, earning profitable freights on return voyages. The ships are of the standardized type, similar to that being built in England.

DURING last year the sale of electric domestic appliances in the U.S.A. showed a tremendous advance, chiefly owing to the growing scarcity of domestic labor; another factor in the increased purchase of appliances has been the better earnings received by the wage-earners generally. A total of 13,545 electrical appliances were placed on the Minneapolis Electric Company's lines during the period from January 1st to November 1st, 1917. Electric flat-irons were the most popular of all devices sold, the total numbering 4,601. Electric vacuum cleaners were next, the total being 3,091. The other appliances in the order of number of sales ranged as follows:—Toasters, 987; washing machines, 612; heating pads, 401; grills, 384; and curling irons, 343.

# The Organization of an Efficient Foundry Costs System

By M. H. Potter

*An efficient costs system is a necessity for the successful operation of the modern industrial plant. Without one the organization throughout is at a loss for information regarding the cost of making and merchandizing the articles manufactured, and no systematic allocation of overhead expenses is possible. In the following article a description is given of one system developed for use in the foundry, the various costs being reduced to a poundage basis.*

DURING the past few years rapid advances have been made in the foundry industry along mechanical lines. Some progress has been made towards better business methods and more efficient systems of organization, but it has been rather slow. The following practical system will effect economies in almost any casting plant.

Gradually, foundrymen are realizing that a well-equipped shop is only half the battle and that correct business principles are equally important. Consequently there is a growing interest in cost keeping, since business, if it be done at all, must be executed at a profit, and work turned out at a loss is worse than none at all.

### Cost Keeping Difficult

One reason why the foundry trade, referring especially to the jobbing shops, has been slow to take up the cost keeping question has been due to the difficulty in working out systems that are efficient, accurate and also inexpensive. The few shops fortunate enough to have good cost systems have jealously guarded the details, with the result that many plants are working in the dark, often bidding low and preventing the whole industry from being conducted on a profitable plane.

It should be stated at the outset that the figures given in the accompanying forms are introduced simply for the purpose of illustration. They are purely arbitrary and, while an attempt has been made to use reasonable values and preserve correct proportions, the figures given do not represent actual costs, either in the shop under discussion or in any other plant.

The cost of castings is estimated on a basis of material and moulding labor ac-

| | | | | | | | | TOTALS. | $600 | $ 650 $1250 |

FIG. 2 DISTRIBUTION OF FIXED CHARGES BY DEPARTMENTS

P is the price of metal per pound.

L is the cost of moulding labor for the casting.

F is a factor which expresses all other expenses in terms of moulding labor.

W is the weight of finished casting.

The factor F is obtained from the monthly cost sheet and includes the following items, each expressed as a per cent of the moulding labor:

F=N+M+I+C+O where N is the non-productive department labor:

M is miscellaneous expense in the moulding department.

I is fixed expense in the molding department.

C is the cleaning department expense.

O is core department expense.

In applying this formula the cost record must be depended upon the furnish the price of the metal per pound, P the cost of moulding labor for the casting L, and the factor, F, the latter being especially important since it involves a burden carried by each separate department, is computed.

Take for example the investment account. The total valuation of the plant based on appraisal and cost of real estate is assumed at $50,000. For the purpose of cost keeping the plant is divided into five departments, namely, melting, moulding, core, cleaning and office. The proportion of the total investment of $50,000, chargeable to each department is indicated in Fig. 2, and a monthly charge based on 5 per cent. interest on the investment in each department is calculated. The investment in department 1, melting, being $22,500, the interest on this sum at 5 per cent. is $1,125 per year, or $94 per month approximately. In a similar manner the monthly investment charge for department 2, moulding, is found to be $56; for department 3, core, $8; for department 4, cleaning, $46, and for department 5, office, $4, or a total of $208 per month, equivalent to 5 per cent. interest in the aggregate investment of $50,000.

**Computing Monthly Depreciation**

The amount chargeable to each department monthly for depreciation is computed in a slightly different manner. As indicated in Fig. 2, there are two columns under depreciation account, which show the total depreciative value of the investment in each department at the beginning of the year and again at the end of the year.

DAILY SUMMARY FOR ONE MONTH.

| WORKING DAY | DATE | TONNAGE | BANK BALANCE | ACCOUNTS RECEIVABLE | ACCOUNTS PAYABLE | CASTINGS SCRAPPED. | FURNACE SCRAP | FLOOR SCRAP | GATES AND RISERS | SALES | LABOR. MOLDING | CORE | CLEANING | FURNACE | OFFICE | TOTAL | No. OF FURNACES RUNNING | No. OF HEATS | No. OF POTS | PUNCHINGS USED | SCRAP USED |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | $ | $ | $ | LBS. | LBS. | LBS. | LBS | $ | NUMBER OF MEN | | | | | | | | | LBS. | LBS. |
| 1 | 1 | | | | | | | | | | | | | | | | | | | | |
| 2 | 3 | | | | | | | | | | | | | | | | | | | | |
| 3 | 4 | | | | | | | | | | | | | | | | | | | | |

FIG. 3 DAILY SUMMARY OF COST ITEMS

The difference between these two quantities in each case is the total depreciation. This amount divided by 12, of course, gives the monthly depreciation charge directly. For instance, in department 1 the total depreciation value at the beginning of the year was $11,250, and at the end $10,460, the difference being 790, or $66 a month. The depreciative value of the entire plant at the beginning of the year is assumed as $25,000, or one half the total investment. While these figures are arbitrary in an actual case the depreciative value never equals the amount invested, since there is considerable property, such as real estate, which does not frequently depreciate and which, in certain cases, may even grow in value. When the various sums of depreciation have been computed in the manner described they may then be reduced to a percentage basis if desired.

Maintenance includes such extraordinary repairs and replacements as cannot be properly charged to depreciation, and which are always too large to be charged to operating expenses. The total of such charges for each department for the year is given in Fig. 2 under maintenance, and these items divided by 12 give the proper monthly charges. In a similar manner the insurance and tax items divided by 12 give the proper monthly charges, using the proper per cent. in insurable value and taxable property in each case as a basis.

The various calculations give a series of monthly charges, which may be transferred directly to the distribution sheet, showing the detailed costs in each department.

A monthly summary, showing the costs of each of the five departments is made out according to the form given in Fig. 1. From this summary the correct value for the factor F in the cost formula is obtained. The greatest simplicity coupled with accuracy has been aimed at in making up these sheets. The expenses in each department are divided into a number of general groups, such as labor, material and miscellaneous expense. The proper items for interest on investment, depreciation, maintenance, insurance and taxes are entered under a general head of miscellaneous expense in each case.

### Division in Melting Department

Taking for instance the melting department, the monthly charge for investment, as shown in Fig. 2, is $94, and under depreciation and maintenance $66 and $23 respectively. These items are set down against investment, depreciation and maintenance under the general heading miscellaneous expense in that portion of Fig. 1 devoted to melting department costs. In a similar manner the monthly fixed charges for the other departments, as given in Fig. 2, are transferred to the distribution sheet, Fig. 1. It will be noticed that the items charged to insurance and taxes in Fig. 1 do not correspond with the monthly charges for insurance and taxes for the various departments as given in Fig. 2. This is because an amount covering liability insurance and special taxes from month to month is added to the fixed portions of these items when they are entered in Fig. 1.

### Office Expense

There is no factor in the cost formula for office expense. This item, which amounted to $1,250 in the expense under

FIG. 1. FORM USED FOR SHOWING THE DISTRIBUTION OF COSTS FOR ONE MONTH

payrolls in the various producing departments. The total office expense, $1,250, consists of salaries $600, and miscellaneous expense $650, as indicated in Fig. 1.

The payrolls in each of the other four departments, melting, moulding, core and cleaning, are $200, $1,200, $100 and $900 respectively, the total being $2,400. The payroll in the melting department, $200, is therefore 8 1-3 per cent. of the total payroll of $2,400. Hence 8 1-3 per cent. of $1,250 office expense is charged to office in the cost of operating department.

The detailed expenses of department 1, melting, are grouped under three headings, namely, labor, expense, miscellaneous expense and material used. Space is also provided on the cost sheet for the total cost as indicated in Fig. 1. The heading expense labor includes $50, office labor charged to department 1, as explained above, and the $200 payroll. The latter covers the wages of the melters and their assistants, the total charged to expense labor being $250.

Under miscellaneous expense are grouped the five items covering fixed charges, namely investment, depreciation, maintenance, insurance and taxes. The method of entering the proper amounts against these items has been explained, miscellaneous expense also includes the amount paid out for crucibles, oil, brick, manganese, silicon, etc.

Since the melting department payroll is 8 1-3 per cent. of the total payroll, $54, of the $650, miscellaneous office expense is also charged with the foregoing items. The melting department is credited under miscellaneous expense with the scrap and crucibles sold, the net sum chargeable to the department being $2,150. In this case it is also assumed that the material used during the month cost $1,700, making the total charged to department 1, $4,100. It is also assumed that 100,000 pounds of castings are shipped. The cost per ton is therefore $82, and the cost per pound is $0.041. The cost per ton at the edge of the furnace, that is the cost based on material melted instead of on castings shipped, is $34 per ton. This figure is obtained by dividing the total cost, $4,100, by the amount of material melted, 120 tons.

### Department Two

The costs in department 2 are grouped under three headings, productive labor, expense labor and miscellaneous expense, also the ratio of the two latter items to the expense for productive labor is computed. The expense labor being $800, and the productive labor $1,200 the former is clearly seen to be 66.7 per cent. of the latter; the sum of the expense labor and the miscellaneous expense is $1,600, or 13.3 per cent. of the productive labor.

Since we have assumed that 50 tons of castings are shipped, the melting loss per ton works out at $56. The total cost for productive labor for the month under consideration being $1,200, the average cost per pound is calculated to be 1.2 cents. The various ratios to productive labor are very important, since they are used in computing the factor F appearing in the estimating formula.

From the foregoing explanation it is clearly evident how the expenses in the three remaining departments, cores, cleaning and office, are calculated. In each of these cases the expenses are grouped under two principal heads, expense labor and miscellaneous.

### Recapitulation

After the detailed expenses of each department have been worked out and the office expense properly proportioned among the other departments, the various totals are recapitulated, as indicated in the lower left hand corner of Fig. 1, and the ratio of all other expenses to the cost of productive labor in the moulding department is calculated. Using the figures which we have assumed this ratio is 296 per cent. The recapitulation, of course, does not include the melting department expenses, since the latter are dealt with separately in the estimating formula. As previously stated this formula is as follows:

$$\text{Cost per pound} \quad \frac{W\,P + L + F\,L}{W}$$

The price of the metal per pound, represented by P in the formula, is obtained from Fig. 1 under melting department expense, where it is given as $0.017 per pound. Fig. 1 also gives the average cost of productive labor in the moulding department as 1.2 cents per pound, and this may be used in computing the term L in the formula for any ordinary casting. In order, however, to have more specific information on this important matter separate records are kept giving the moulding time, and therefore the moulding cost of each job, with which new work may be compared. This is a more satisfactory method, since the average figure has only a limited application and is liable to lead to erroneous results if not properly applied. The individual records of moulding time indicate that the moulding time indicate that the moulding cost varies from $5 to $50 a ton. The factor F in the formula is obtained direct from the recapiulation in Fig. 1, and in this case is 296.

The application of the formula in connection with the cost quantities given in Fig. 1 may best be explained by an example. Assume for instance a connecting rod weighing 50 pounds. Assume also that the weight of the heads and rises is equal to 20 pounds, so that the total weight of the rough casting is 70 pounds. The cost of the casting is as follows:

$$\frac{W\,P + L + L\,F}{W}$$

$$\frac{(70 \times 1.7) + (50 \times 1.2) + (60 \times 2.96)}{50} = 7.15$$

cents per pound.

No cost system is absolutely accurate and the efficient system is the one which gives the most accurate results at the least expense. It is thought that the system described herein is specially noteworthy for its accuracy combined with economy. This is an important characteristic, since a cost system which is not accurate is worse than none. In fact, it is probable that more managers are led astray by false statements found in their cost records than get into trouble through the lack of any system at all.

Of course the human element enters into this phase of the question, it requiring no little amount of moral courage to face the actual figures when business is going badly. It is very easy in such cases to juggle the cost items a little so that they will give a favorable appearance, but this is encouraging a practice of self-deception that is very dangerous.

## A BIG INCREASE IN CANADA'S TRADE

AN increase of $315,292,044 in the trade of Canada during the fiscal year ending on March 31 last is shown by the monthly statement issued through the Customs Department. The statement shows that at the end of the last fiscal year the grand total of Canadian exports and imports was $2,564,482,215, as against $2,249,170,171 at the end of 1917. Domestic merchandise exported from Canada last year totalled $1,540,027,786, while the imports during the same period were $962,521,847. Foreign merchandise was exported to the total of $46,142,004.

Dutiable goods to the amount of $542,319,623 were imported into Canada during the year just ended, and free goods to the amount of $420,202,224. Duty collected during the year totalled $161,588,465, as compared with $147,623,230 in 1917. The imports of coin and bullion during 1918 were $12,279,173 against $28,081,120 in the previous year.

Although the total trade of the Dominion shows a marked increase in the year, the statement shows that there was a falling off in exports and imports in the month of March as compared with a year ago. In March, 1917, the total trade was $230,722,774, while during the past month it amounted to only $191,737,332. Of this total $87,255,698 represented merchandise entered for consumption in Canada, and the exports totaled $99,854,987.

Products of Canadian factories to the total of $636,602,516 were exported during the past fiscal year, as compared with $477,399,676 in 1917. Exports of domestic agricultural products reached a total of $567,713,584, and animal products exported amounted to $172,743,081. Products of Canadian forests were sent out of the country to the amount of $51,899,704, and Canadian minerals exported totaled $73,760,502.

## BRITISH INSTITUTIONS FAVOR DECIMAL COINAGE

THE question of a reform in the British coinage system has been urged for some time, and the movement has now gathered weight to such an extent that the advantages of the decimal system are

more generally recognized. In a report issued by the British Decimal Association details are given of a system which has been agreed upon as convenient and desirable by the Institute of Bankers, the Association of Chambers of Commerce of the United Kingdom, and the Decimal Association after lengthy deliberation in joint conference by these bodies.

### Eliminates the Penny

In considering the question of a change from the present to a decimal system the first difficulty to be dealt with is the fact that the penny is not a decimal submultiple of the pound sterling. It is considered wholly undesirable that any change should be made in the pound sterling, because of its universal recognition in the settlement of international transactions, and it has been decided, therefore, to retain it as the British standard monetary unit and to eliminate the present "penny" coinages, replacing the latter units by an entirely new series. The silver coins of the values of crown (5s.=$1.22), half-crown (2s. 6d. =$0.61), and threepence ($0.06) are also to be withdrawn.

The suggested coins are to be termed "mil," and the recommendations jointly agreed upon by the bodies above mentioned advise the adoption of the following table of currency:

| Coins | Value in £ | Value in Mils | Equivalent Value in Pres. Currency |
|---|---|---|---|
| Gold or Notes | | | |
| Sovereign ..... | 1.000 | 1,000 | Sovereign |
| Half sovereign .. | .500 | 500 | Half sovereign |
| Silver— | | | |
| Double florin .... | .200 | 200 | 4 shillings |
| Florin ..... | .100 | 100 | 2 shillings |
| ½ florin or shill. | .050 | 50 | Shilling |
| ¼ florin or sixpence .. .. .. | .025 | 25 | Sixpence |
| Nickel— | | | |
| 10-mil piece .... | .010 | 10 | 2.4 pence |
| 5-mil piece ..... | .005 | 5 | 1.2 pence |
| Bronze— | | | |
| 4-mil piece ..... | .004 | 4 | 0.96 pence |
| 3-mil piece ..... | .003 | 3 | 0.72 pence |
| 2-mil piece | .002 | 2 | 0.48 pence |
| 1-mil piece ..... | .001 | 1 | 0.24 pence |

It is urged that by this system it will be possible to adjust the price of goods or services more equitably and in more finely graduated proportions to the fluctuations in cost than is now possible. Under present conditions, it is pointed out, while the cost of many necessaries may increase by 20 per cent., the retailer must raise the prices of halfpenny goods and services by 100 per cent. to 1d., or of penny goods by 50 per cent. to 3 halfpence, for, although farthings (one-quarter penny) are coined, they are rarely used. British banks do not accept for deposit or pay out any fraction of a penny, but if the suggested system were adopted the smallest coin in value would be recognized.

## BRITISH INDUSTRIES FAIR

THE British Industries Fair, which has just closed, was held at the London Docks. Only British manufacturing firms were permitted to exhibit, and no exhibitor was allowed to show articles other than those of his own manufacture.

The main trades represented were those concerned with earthenware, porcelain and china, glass and glassware, fancy goods, stationery and printing, paper, toys and games—all affording evidence of the ability of British firms to capture business formerly in the hands of German and Austro-Hungarian competitors.

Special mention may be made of the exhibits by the group of exhibitors known as the British Chemical Ware Manufacturers' Association, wherein were centred key industries of paramount importance—glass, porcelain and filter paper for scientific purposes. The association comprises firms which have entered whole-heartedly into the problem of supplying our chemists, physicists, bacteriologists and medical men with many of their most urgent requirements; and an extensive variety of apparatus of excellent quality and design was displayed. Remarkable progress has been made with these commodities since the Fair of 1917. In engineering glassware, several firms showed ships' lantern dioptric lenses, railway lamp glasses, electric light and arc lamp globes and shades, gauge glasses, reflex glasses, protector glasses, cylinders, needle lubricators, miners' lamp glasses, etc.

## MARKET FOR OIL ENGINES IN ENGLAND

E. HALDEMAN DENNISON, U. S. consul at Birmingham, England, reports that there is a good demand in the Birmingham district for agricultural implements, particularly oil engines and tractors. Though a substantial amount of iron and steel has been released for the purpose of meeting these requirements, home manufacturers are experiencing some difficulty in meeting the demand. Even with regular importations from the United States and Canada there are arrears which, it is feared, may retard farm operations.

Oil-driven engines of moderate power are being called for in increasing numbers by agriculturists. Some of these are made in the district and others are imported. Engines of about 2¼ horsepower are being installed for the operation of mechanical milkers and other purposes, while for what is known here as "barn work" (pulping, chaff cutting, etc.) many engines of somewhat larger capacity are being sold.

While some British firms are building heavy tractors for breaking up the grass lands that are to be brought under wheat cultivation, they are unable to give the attention to the development of this branch that the occasion demands. A considerable proportion of the tractors now being acquired by individual farmers are of the type introduced from the United States by the Board of Agriculture. The ploughs attached to them, however, are more frequently of British make. They are adapted to the simultaneous ploughing of three or four furrows, according to the character of the land and the power of the tractor. Coming from plants of manufacturers who have gained their experience largely in the automobile industry, the domestic tractors are built with vertical engines, whereas in the United States the horizontal engine receives the preference. Some of the tractors are applicable only to agricultural operations; others can be used also for general road transport. Some of the smaller rural authorities are purchasing the latter type.

## WHAT IS A SKILLED MAN?

THE following definition regarding skilled workers and others is advanced by a correspondent in an English contemporary.

1. A skilled man is essentially a man who has served an apprenticeship (indentured or other) to the trade in which he is and has been continuously employed since completing such apprenticeship. He is capable of exercising his skill independent of his surroundings.

2. A semi-skilled man is a man who, not having served an apprenticeship to the trade in which he is employed, has acquired some skill in some portion or portions of the work which would otherwise be performed by a skilled man. He is only capable of exercising such skill as he may possess under certain conditions.

3. An unskilled man is one who performs any operation not requiring manual dexterity of any kind.

4. Both semi-skilled and unskilled men may have a special knowledge which is of importance in the particular work they are employed on but such knowledge cannot in any way amount to skill.

## AUTO IMPORTS TO CANADA

ACCORDING to the Department of Customs report for the fiscal year 1917, which has been tabled in the House of Commons, Ottawa, the total importations of automobiles for the fiscal year 1917 included 12,037 cars, valued at nearly $8,000,000, or one dollar per head for the population of Canada. There was almost as large a sum spent in the importation of parts, but these were largely for the manufacture of new automobiles in Canada—a Canadian industry. If the importation of entire passenger automobiles were prohibited outright, Canada would lose nearly $3,000,000 in duty. The figures for 1917 follow:

| | Value | Duty |
|---|---|---|
| Passenger autos .. | $7,981,177 | $2,790,256 |
| Freight autos .... | 423,824 | 148,338 |
| Motorcycles, etc. .. | 177,621 | 62,071 |
| Motor vehicles,parts | 7,200,017 | 2,171,723 |

ACCORDING to statements made by merchant captains arriving at ports in the United States the periscopes of German submarines are now being nickel-plated or bronzed with aluminum in order to make them invisible. This process, it is claimed, reflects the colors of the surrounding water and leaves the periscope indistinguishable from the water. The officers said the fact that so many steamships of late have been sunk without anyone aboard having seen any sign of a submarine is proof of the truth that the U-boat periscopes have been rendered invisible.

# U. S. Shipping Board: Its Handicaps and Accomplishments

By Edward N. Hurley •

*[illegible] transportation is the supreme question of the hour. Rumors and rumors have created some degree of uncertainty regarding the progress of [illegible]. On March 26 the following address was delivered before the National Union League at New York. The facts and figures are silently eloquent.*

If by [illegible] a bridge could be thrown across the Atlantic over which our armies, their artillery and supplies could move rapidly and unhampered to the battle lines in France, would any military man in Berlin, Vienna, Rome, Paris, London, or Washington have any doubt but that the world would be made safe for democracy before the year goes out? We have the men, we have the guns, we have the supplies, but without means of getting them to the front we might as well be without them. And unless we get our men to the battle line we will not win this war.

### Start Under a Handicap

So it all comes back to ocean transportation—to the vital need of ships. Fail there and we fail utterly. Upon the Shipping Board has devolved the responsibility of supplying this need, and supplying it under the most extraordinary conditions that ever existed-supplying it at the most crucial period of the war's history—at a time when every other industry is being taxed to its utmost capacity in the matter of materials and labor to provide [illegible].

The handicaps have been many. We were not a maritime nation. Our flag had almost vanished from the seas, and with the exception of a few widely scattered shipyards, merchant marine construction had almost become a lost art with us. Then came this sudden call to outdo the rest of the world in the upbuilding of a merchant marine; a call coming at a moment when the navy was undergoing the greatest expansion in its history, when most, if not all, of the established yards were feverishly engaged [illegible], destroyers, submarines, fuel ships, tenders, and other auxiliary craft, and when [illegible] called to government navy yards or private shipbuilding plants.

VIEW OF SLIP IN SHIPYARD SHOWING TYPE OF TRAVELLING CRANE AND SCAFFOLDING INSTALLED.

[illegible] by Committee on Public Information.

From the ground up, but of first securing the ground upon which to make a start, some of it marsh land which had to be filled in before launching ways could be laid. Therefore we who are engaged in the work appreciate the magnitude of the task. I doubt if its magnitude is generally realized. I am not here to emphasize that magnitude—I am not here as an optimist glorifying an outcome—I am not here as a pessimist saying the task can not be accomplished. I am here to tell you of the situation as it is—to deal with facts as they exist—to lay all of our cards upon the table, and face up.

When we took hold of this job of shipbuilding, we found there was not shipyard in existence with which we could place an order. The old yards, with their trained force of shipbuilders, were filled to capacity. We had to establish the yards first, get the shipbuilders to take charge of them and train the men to build the ships.

There were 17 steel shipyards in America at the time of our entrance into the war. We have located 81 additional steel and wood yards, while 18 other yards have been expanded. Does America realize what this job means? Does it realize what a tribute is paid to its own initiative in this achievement?

### Big Job in a Big Way

We are building in the new and expanded steel yards 235 new steel shipways, or 26 more than at present exist in all the shipyards of England. If we had been content with doing the job in a small way, we might have built a few new yards, and added a little to our capacity. A few ships might have been finished more quickly; but it was the spirit and will of America to do the job in a big way, and the judgment of the country will be vindicated by the results when all these new ways are completed and are turning out ships. Many of these ways have actually been finished. The new industry we have created will make America the greatest maritime nation in the history of the world.

### Battle With the Elements

Struggling against something that can not be avoided is more baffling than struggling against something that can be. You can appeal to striking men to go back to work, but you can make no appeal against zero weather. We did what we could. We told the new shipyards to go ahead and use dynamite in locating their pilings. The men in those new yards fought the bitter winter. They had the same spirit and demonstrated the same pluck and unselfishness as the men in the trenches. They have virtually completed the job of building America's new shipyards—the new yards that will make us the greatest shipbuilding nation.

It has been an uphill struggle. I am willing to confess there have been times when we have been discouraged, not at the magnitude of the task, but through a doubt of human ability to accomplish the stupendous work in the short time

But we have had our moments of elation when we have felt that we are making progress. The record made by the Skinner & Eddy Co., of Seattle, is a case in point. That company laid the keel for an 8,800-ton vessel, which was launched in 64 days. She was delivered to the Fleet Corporation on January 5, and started on the first voyage on January 14. This record accomplishment shows what can be done in live, wide-awake efficient American shipyards.

### Steadily Taking the Water

Then a few days ago we received a telegram from the Moore Shipbuilding Co., of Oakland, Cal., announcing the

successful launching of one of their large vessels. Twenty minutes later we received another telegram from the same company announcing the launching of a second ship of the same type, and 40 minutes afterwards a third telegram saying that a third vessel of similar character had gone overboard.

There are two methods for computing the construction of tonnage to show what is accomplished. One is by showing the tonnage in the water; the other is by showing the tonnage under construction. But when a great many ships are put under construction at the same time the question that should be asked is, How are they all progressing; how near to completion is the vast program? Here is the answer:

### Steel Construction Tonnage

The total amount of our steel construction program on March 1 was 8,205,708 dead-weight tons. This is made up of 5,160,300 dead-weight tons under contract with the Emergency Fleet Corporation, and 3,045,408 dead-weight tons of requisition vessels.

Of this total steel construction, 2,121,568 dead-weight tons, or approximately 28 per cent., has been completed. That means that in addition to the building of our big new yards we have also been building ships. That is, the program for steel ships has advanced 28 per cent. toward completion. Of the amount of steel ships under contract and under requisition, 655,456 dead-weight tons, or approximately 8 per cent., were actually completed and in service on March 1 of this year, nearly a month ago. This amount of floating tonnage exceeds our total output in 1916, including steel, wooden, and sailing vessels, by approximately 50 per cent.

In the yards which we have already completed and those which are nearing completion the progress will be cumulative from this time on.

### Building Yards and Ships

Thus, while we have been building the yards and training the new forces necessary to construction, we have also been building the ships.

Notwithstanding the difficulties of organization, of the handicaps of bad weather conditions, of transportation embargoes and railroad congestion, nearly as much tonnage has been constructed in American waters in the past three months as by all the other maritime nations of the world combined.

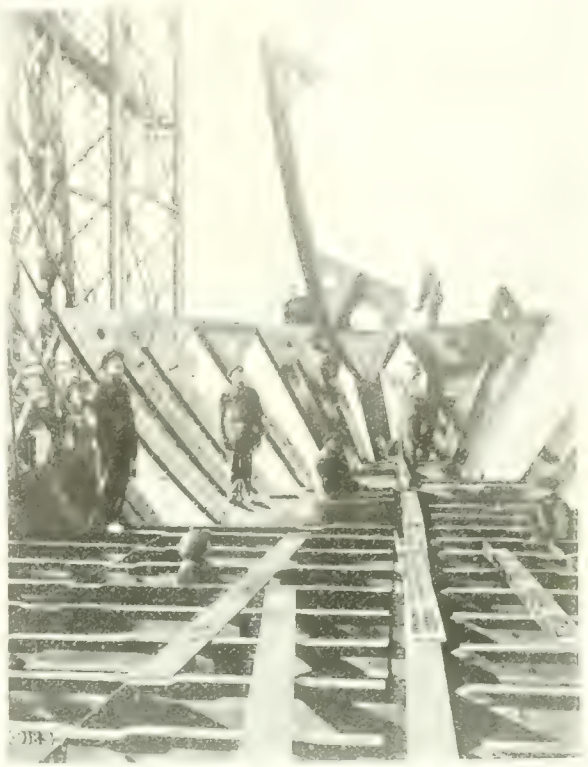
I have referred to the necessity of providing additional facilities for the building of ships. That is, for the creation of new shipyards, for enlarging old ones, for the education of new shipbuilders, and, I may now add, the necessity of providing increased means for obtaining engines, boilers, turbines, and other equipment. At the outset the 37 old steel yards began increasing their capacity until they now have 195 ways as against 162 eight months ago. Other parts of their plants have increased in proportion. We then made provision for additional new steel yards, some of which have been given financial assistance by the Emergency Fleet Corporation. Thirty additional new steel shipyards are thus being created, with a total of 203 shipbuilding ways. Thus we now have in the aggregate 67 steel shipyards either wholly or partly engaged in Fleet Corporation work. These yards will have a total of 398 steel building ways. Of these 35 yards, with 258 ways, are on the Atlantic and Gulf coast; 19 yards, with 66 ways, are on the Pacific; while 13 yards, with 74 ways, are on the Great Lakes.

VIEW OF STEEL HULL IN COURSE OF CONSTRUCTION. THE MEN ARE PLACING FRAMES IN POSITION FOR RIVETTING TO THE KEEL

Copyright by Committee on Public Information

### Wooden Ship Construction

Our program for building wooden ships has been beset with many difficulties and handicaps which could not



ASSEMBLING THE LOWER PORTIONS OF THE BOW FRAMES OF A STEEL SHIP

Copyright by Committee on Public Information

well be foreseen. A year ago wooden shipbuilding in the United States was almost a lost art. We found 24 old wooden shipyards with 74 ways. The capacity for wooden shipbuilding has been increased until we now have 81 wooden shipbuilding yards, with 332 ways completed or nearing completion.

Assuming that these ways will each produce two standard ships per year, we should turn out about 2,300,000 dead-weight tons of wooden ships annually. These 332 wooden shipbuilding ways, now nearing completion, added to our 398 steel building ways, will give us a total of 730 berths upon which to build steel and wooden vessels. When you consider that we had only 162 steel building ways a few months ago and 73 wooden shipbuilding ways—a total of 235—an increase is shown of 495 wooden and steel berths on which we can build ships.

### Delayed by Railroads

Our program on wooden ships was delayed by the fact that we were unable to provide the necessary big timber in sufficient quantities from the forests east of the Mississippi River. We found ourselves obliged to go to the west coast and arrange for the transportation of hundreds of carloads of Douglas fir, which it was necessary to substitute for long-leaf yellow pine for keels and other heavy timber. Here again we encountered a serious phase of the transportation problem. Our shipments were held up for weeks by the railroad embargo.

RIDING THE LOAD IN A SHIPYARD. THE MEN ARE CARRIED ON A SHIP'S RUDDER.

Copyright by Committee on Public Information.

the shipbuilding program caught the turbine and engine manufacturers totally unprepared. In the past the engines for ships built in this country had been manufactured at the shipbuilding plants. As contracts for new shipyards were given it became necessary to increase the turbine and engine building capacity at the same time. Special tools of all kinds were required for the engine builders' shops, and these tools had to be secured from manufacturing shops already overcrowded with war orders. In addition to this, the severe weather and the transportation tie-up seriously delayed the construction of some of our largest turbine-building plants. We anticipated delay during the earlier months for lack of the turbines and engines, but expect to make up for the early shortage.

### First Concrete Vessel

The proposal to build ships of concrete was first regarded as a fascinating absurdity. On March 14 there was launched from the yards of the San Francisco Co. the first concrete steamship, a vessel which the builders christened Faith. We hope she will exemplify her name. The builders believe she will, for in the telegram announcing the successful launching of the vessel were added these words: "Appearance after launching warrants us in saying to you that we believe this form of construction may be safely depended upon."

Now as to labor—[illegible] right arm. There has been much talk of conscripting labor—of forcing it into shipyards as our soldiers have been brought into the camps. I am fully aware that I am flying in the face of a growing popular sentiment that men should be drafted into the industry which supports the battle lines, but I wish to put myself on record as being opposed to the conscription of labor. I do not believe conscription necessary, for I believe labor itself will produce conditions which will render idle all thought of conscripting workmen. The vast majority of our workmen are men of intelligence, and when they come to a full realization of the fact that any defection on their part now will injure their fellow-workers in almost every field of industrial activity, I feel sure they will respond to all demands made upon them. Unless they fully do their part, their brothers will suffer.

### Labor Loyally Expected

It would be useless to manufacture material and supplies and pile up the products in the wharves if there are no ships to transport them. So unless our ship workers do their best, other industries must slow down or halt completely, with the result that thousands of workers throughout the country will suffer for lack of employment.

I believe that labor has begun to realize that fact, but I want to drive it home to them, for there are some, I regret to say, who do not yet sense their responsibility. There are many who are not working to their full capacity. There are many who, because of the high wages they are earning, are prone to take too many holidays. Labor generally throughout our shipyards is to-day receiving the highest rate of wages ever paid for similar work in the history of the world. The additional cost of our ships, due to increased wages in shipyards covering the program we have mapped out, will be in excess of $300,000,000. We expect, and we have a right to expect—the country has a right to expect—that labor will render for this increase of wages a corresponding increase in production—that is, the output of ships.

### Confidence in Leaders

All has not gone smoothly in the labor situation, and there have been times when this phase of the problem was enough to cause discouragement. The vast majority of laboring men are patriotic; the leaders whom I have known through close contact in Washington, especially Mr. Gompers and his immediate associates, have my confidence, and the country recognizes their patriotism. With only one exception the leaders of the shipyard crafts generally have shown a spirit of co-operation, ready to sink their personal differences in the common pool of patriotism.

We have established a labor adjustment board whose complete fairness can not be questioned.

We have felt that it was our duty to see to it that the problem of housing the workmen in these vast new plants we have been creating was solved with care. We have not rushed into this work with closed eyes. Our duty is to guard the public expenditures; to see to it that there is no abuse of the liberality of Congress in the matter of appropriations. Every dollar expended must bring a dollar's worth of return to the Government. The cost-plus system has been banned by Congress in the housing op-

ASSEMBLED COMPONENT OF SHIP'S FRAMING AWAITING INCORPORATION WITH THE HULL.

—Copyright by Committee on Public Information.

erations, because Congress itself, as well as the rest of us, have felt that there should be a greater check, not merely upon profits but upon the actual cost of all work done for the Government.

### Army of Reserve Workers

The new yards have been established, wherever possible, away from the congested districts, and while this was necessary, it brought with it the problem of transportation, as well as of housing. We are arranging now for proper transportation, as well as for proper housing.

We have recruited a volunteer force of 250,000 highly skilled mechanics who have, with a patriotism that has made us all proud, agreed to hold themselves in readiness for our call. These men are being held in reserve, remaining in their present employment until such time as in the development of our yards the demand arises for their services.

### The Fabricating System

This brings me to the point where I desire to make a brief reference to what have been popularly termed our three fabricating shipyards. The term is more or less a misnomer, for these yards, located at Hog Island, Newark Bay, and Bristol, Pa., are in reality assembling yards. The shipbuilding materials which will go into the making of vessels launched at these yards are being fabricated in scores of steel plants, scattered throughout the country as far west as Omaha, Neb. In some instances 95 per cent. of the work on these materials is being done at points far remote from the shipyards. The so-called fabricated ship is almost a new method of ship construction—almost as new to England as it is to us. But from the progress of the work as it has thus far developed we are confident that it will be the means of adding millions of tons to our merchant marine.

When the high point in the curve of production finally is reached and the magnitude of America's shipbuilding program is realized it will be a continuous performance of production and launching.

There is no doubt that we are destined to be one of the leading shipbuilding nations of the world.

## BRITISH WEST INDIES TRADE

CLOSER commercial relations when the war is over between Canada, the British West Indies and contiguous British territory is a subject that is receiving some attention at the present time among upper Canadian manufacturers and shippers.

It is one that has a deep interest for the Maritime Provinces, as any development in the direction referred to must inevitably lead to increased shipments through the maritime ports of St. John and Halifax, and must also tend to stimulate the manufacturing industries of these lower provinces.

### Tariff Increases Trade

As a result of the operation of the preferential tariff, says the St. John "Board of Trade Journal," there has been a slight increase in the trade between Canada and the British West Indies. In the last fiscal year the imports from the West Indies reached a total of $14,239,595, as against $6,354,991 in 1916. Exports from Canada did not show the same ratio of increase, the figures for 1917 being $5,179,083 and for 1916, $4,134,901. It is quite apparent from the above that the manufacturers and shippers of Canada are not getting all out of the trade that they should get, or that they might obtain under improved transportation conditions.

The "Barbados Advocate," in a recent article on the subject, remarked:

"It cannot be too strongly pointed out that this one market, that of the British West Indies, is comparatively close at hand, is waiting for further development, and possesses these direct advantages that the merchants there are strongly desirous of having more extensive and closer trade relations with us, and that, already, throughout these colonies there are active branches of two leading Canadian banks, ready to assist with information and banking facilities in developing our trade."

### Fast Steamship Service

The same paper declares that these advantages would be futile if they were not linked with such transportation conditions as more frequent and quick steamship services between near Canadian ports and the British West Indies, fast through freight services with Canadian business centres timed to meet the arrival and departure of the steamships, and through freight rates and charges between the West Indies and Montreal and Toronto via a Canadian port and not exceeding those via New York and Boston. There must also be cold storage facilities; cool, ventilated accommodation, especially for fruits, in both steamships and cars, rapid sailings and prompt handling of cargoes.

These results can be obtained by the utilization of the advantages possessed by the Canadian ports of Halifax and St. John. Both possess peculiar advantages. St. John has western connection by two transcontinental lines, the Canadian Pacific Railway and the Canadian Government Railway; Halifax has the latter line of railway. There is practically little difference in the ocean distance between the two maritime ports and the West India Islands. The advantage in this respect is with Halifax, but there is only a difference of twenty-one miles. Against this short ocean advantage, St. John has the advantage of a very much shorter land haul by both transcontinental lines. By the Canadian Pacific Railway the combined rail and ocean mileage from Montreal to Bermuda via St. John is 1,254 miles, while via Halifax and the Canadian Government Railway it is 1,588 miles. In the shipments north of the molasses crop of 1917 a much larger proportion came via St. John, illustrating the advantage that the shorter rail haul to the interior gives to St. John.

Clearly, the two ports must work together in this as well as in other national enterprises involving the use of lower province ports.

Concentration of the business thought of Canada upon the whole question is very much needed at the present time, so that when the war is over no time may be lost in putting plans into effect.

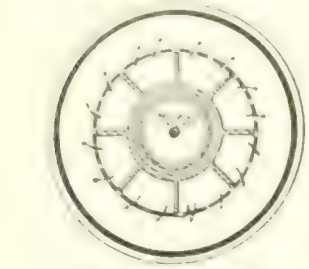
## SHIP'S AIR PURIFYING APPARATUS

DIFFICULTIES with the attuning apparatus of radio receiving and sending instruments have been the subject of experimentation by William J. Baldwin of New York, who recently designed an apparatus for a radio room that would admit air not only separated from rain, salt spray and spume, but that would also condition or regulate the humidity within the room by keeping it at a common standard of humidity, regardless of the outside changes.

Cold water in the spray form will do this, provided the spray can be gotten rid of after it has combined with the excess of humidity (steam in the air) and then separated from the air by some practicable form of apparatus that is simple and clean, and that occupies small space.

While a shower of rain will clear the atmosphere, the elements of nature have all outdoors in which to set up the appa-

as small as a cabin or radio cabinet.



Section X-Y

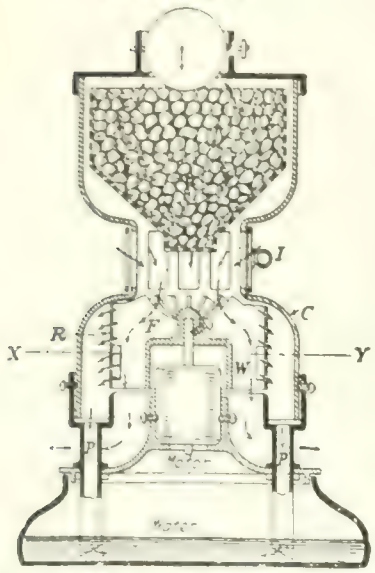


FIG. 1—SECTIONAL ELEVATION OF BALDWIN AIR DRYER AND COOLER.

apparatus was used similar to one designed two years earlier for the purpose of precipitating the $CO_2$ when found in great excess in a confined space, as in the hold of a submarine, when forced to stay a long time under water.

In this machine a spray of potash water was used in connection with a mechanical dust precipitator for the purpose of seizing on the carbonic acid in the air and thrown it down, so to eliminate the $CO_2$ at the dust and water discharge of the apparatus.

It was proposed to put the apparatus in a bulkhead; the discharge side of the apparatus coming into the air of the living quarters, the air freed of its $CO_2$ being forced back again into the chamber of greatest vitiation, thus forming a cycle.

In the general experiments it was found that a prepared spray of chemical liquid or even cold water not only seized the dust but on the other gases in the air, with which the chemical in the spray would combine, and that a pure-water spray turned into the apparatus would keep the humidity of the air constant by suitable regulation of the temperature of the water spray. In a room of 90° F. and a humidity of almost 90%, it was possible to drop the humidity to 45% by reducing the temperature of the spray to 70° F.

A simple form of the apparatus arranged for cooling a room is shown in Figs. 1 and 2. The apparatus from the inlet to the line X-Y (Fig. 1) is an ordinary fan or blower F, and the downward extensions of the fan blades or wings W are necessary to accelerate the rotary motion of the air.

The rotor R is a rotating hoop of permeable metal, against the inner side of which the air is thrown with all its impurities. If the heavy particles in the air, such as dust, mud or particles of water, strike into the perforations of the hoop, they pass through into a quiet space formed by the outer case C. Or, if they strike on the solid part of the hoop, they are rubbed through the nearest holes by the forward movement of the air. They then pass into the quiet space C, drop down within it, and escape by the pipe or pipes P into the tank.

The air does not escape with the heavy particles, as might appear at first, for the lower ends of the pipe legs are sealed by the water in the tank. The tank may be of any shape, or there may be no tank, the separated particles going to a waste pipe.

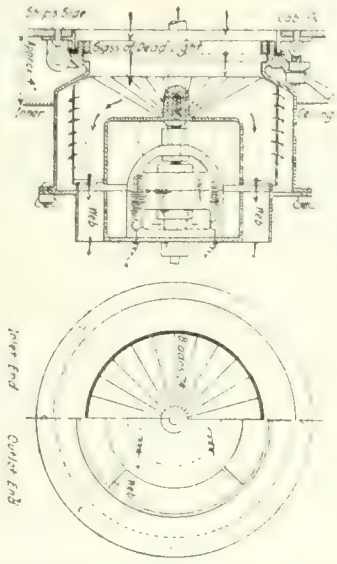

FIG. 2—ARRANGEMENT OF APPARATUS ADAPTED TO SHIP'S PORT-HOLE.

The greater the velocity of the rotor R the more efficient is the apparatus. A speed of 5,000 ft. per min. is very practicable, but 10,000 is not excessive, either from the point of bursting or for any other reason.

The fan gives the same static pressure as any other centrifugal blower of equal diameter and speed and requires only equal power for equal work, and the power required for separation and friction is considerably under 25% of the blower power required to move the air.

The device as described above illustrates the principle of the various types of apparatus, whether used for taking the dust from the air, the $CO_2$ from a chimney or an enclosed space, the excess of humidity from the air, throwing down fog, cooling and moving air, etc. It will be noted that the ice in the upper tank serves both as a cooling medium and for the supply of cold water, broken into spray by the rapid motion of the fan, for the purification of the air.

FIG. 3. ARRANGEMENT OF APPARATUS FOR REMOVING FLUE DUST FROM CHIMNEY GASES.

## BAY OF FUNDY SAFE

THERE was a time in the history of the Bay of Funday when some fears respecting its safe navigation were justifiable, but these days have long since gone by. With the protection that is thrown around the mariner in the way of lighthouses, lightships, for alarms, automatic buoys, bell-buoys and other forms of precautionary signals, the perils of the Bay of Funday navigation have now been almost wholly eliminated. This is borne out by the fact that for the past four years, though 22,614 ships, of a tonnage of 13,660,866 tons have passed in and out of St. John, coming from or going overseas, there has not been a single casualty of any consequence to any of them in the Bay of Fundy.

Some years ago, when the question came before the St. John Board of Trade, a careful study was made of the wreck record for a period of eighteen years subsequent to 1896 with the result that it was shown that with a total tonnage of 42,029,262 tons entering the port, the casualty average was only .033 of 1 per cent. This statement was based on the whole Bay of Fundy from Cape Sable up.

The statements above made as to the safety of the Bay of Fundy were fully established in the evidence submitted to the Special Pilotage Commission (which sat in St. John recently) by several masters of ocean steamers using this port. The pilotage service in the Bay of Fundy was also favorably commented upon. To make the pilotage service more effective it was recommended to the commission that the present three districts be consolidated into one and a pilotage station established about eight miles below Partridge Island.

The suffocating poison gas first used by the Germans is not chlorine as generally supposed but phosgene, which is a combination of chlorine and carbon monoxide. This powerful gas is an important factor in the manufacture of synthetic colors. Here is a case where a German peace product was immediately available for military offensive.

# Some Considerations Regarding Modern Plant Organization-V

By M. H. Potter

*The factors which enter into the successful manufacturing business of to-day are interdependent to an ever-increasing degree. Location, type of building, transportation facilities, staff organization and plant equipment are features which require to be considered both singly and as a whole in relation to the particular product to be undertaken. A clear and concise idea of such considerations is necessary before entering any one line of manufacture.*

### Cost Records

A CONVENIENT system of indicating what work shall be got out by the shop has been found to be a system of orders, known as production orders or shop-work orders. These orders must be capable of being separately identified, and it will be readily understood that to give each the actual name of the work in progress would not be practicable; therefore, a system of numbers is used, and by the number given to a work order the work is known in all its stages.

It is desirable to allot a series of numbers for standing orders. The distinction between a factory "standing order" and a "factory work order" is that the former is an order, which stands until changed, to perform certain work in the nature of expense, and to which such material as may be used is charged, also the labor pertaining thereto, while the work order is issued to authorize work to be got out in the nature of product and to identify it while in progress of manufacture.

### The Cost Clerk

One clerk to be known as the cost clerk—with such assistance as may be necessary—should be responsible for the operation of the cost system. In the equipment of his department there is ample opportunity for the use of cards, indexes, loose-leaf records, and other convenient and quick helps in the assembling of cost data.

### Importance of Exactness

If system is desirable in the workshop in obtaining records, orderly methods should also obtain in the cost department to permit of the information furnished by the factory records being assembled for entry in the cost accounts with reasonable promptness. This is necessary if the cost system is to be effective.

The entry in the cost accounts of charges from factory records should never be allowed to be in arrears. It is not unreasonable to expect that the entry of charges in the cost records shall be overtaken on the day succeeding that in which they occur. Cost accounts lose much of their value when the information they purport to give is delayed for weeks after the completion of the product.

If the system of obtaining costs is found to affect the promptness with which records should reasonably be expected, then the cause of the delay must be located and an immediate remedy provided, whether it be in the factory or in the cost department. It may be that the clerical assistance is inefficient, or, if it is efficient, the work is in excess of the means to overtake it. These conditions are also capable of adjustment.

If the cost of machine operating is kept, the cost ledger should contain accounts with the various machines. The form of ruling to be used in the cost ledger accounts will be as varied as the industries for which it is required. There should, however, be sufficient provision for analytical detail to show quickly what the cost is, and what it contains.

FORM 3 SUMMARY RECORD OF MATERIALS USED.

departments, and the fourth copy is retained by the purchasing department.

### Method of Working

The goods having been received, the invoice accompanying same is compared with the order and checked as to quantity and quality; the invoice is then passed to the purchasing department for approval of prices, after which it is sent to the accounting department. The prices mentioned in the invoice are now entered on the copy of the original order which the accounting department has received, and the order is sent to the factory superintendent, who exchanges his copy for the one he now receives, first checking with his requisition to verify the fact that all goods required have been ordered and shipped. The factory bookkeeping department next enters upon the stock record the quantity and prices of the goods.

For the verification of receipt of goods, prices, extensions, all necessary approvals and the ledger folio of the creditor and the designation of the account which is to receive the debit, a form should be rubber-stamped on some convenient space on the invoice. A cover on which is summarized the charges and credits contained within is then fastened to the invoice, and through this medium posting can be made directly to the accounts affected. In practice, however, it has been found advantageous to post only the creditors' ledger from the invoice, carrying the debits to a purchase summary, from which monthly totals are posted to the general ledger accounts.

### First Necessary Requirements

The raw material having been received, a stores ledger is necessary in order to keep a summary of the following:

1. Material received.
2. Material used in the factory.
3. The exact amount of material used on any particular piece of work.
4. Data to maintain a running or perpetual inventory. One card or page is allotted to each article purchased. (See Form 1.) From this it will be seen that when goods are received the stock clerk places at once on the debit side of the card the date of receipt, quantity purchased and unit price.

### Withdrawals

When goods are to be withdrawn from stock for use it should be done only by requisition, prepared usually in triplicate, and properly signed by some one competent. This requisition contains at the top the number of the order against which the material is to be charged, the date, and the quantity desired (see Form 2).

NAME _____ DATE _____ WORKMAN'S No. _____

| ORDER No'S | No HOURS | UNIT RATE | EXTENSION |
|---|---|---|---|
| | | | |

FORM 4- TIME CARD ALLOCATING TIME TO VARIOUS WORK ORDERS.

One requisition should be used each time material is drawn, each order having a separate requisition. The worker requiring the goods should go to the clerk who issues the goods, secure on one requisition a proper receipt, file this, and on the other requisition make an extension from the stock card of the cost of the material issued. This requisition is then sent to the accounting department, where it is entered on a summary sheet of materials consumed (see Form 3) the amount being extended to the column designated to correspond with the order number against which the goods are drawn. This sheet is totaled every period and the total charged in the cost ledger to the respective order. In the general ledger manufacturing is debited, and materials and supplies credited.

A trial balance of the stores ledger should be taken monthly, its balance of stock may be verified by checking with the physical inventory at regular periods or at such times as the various items of stock are at a minimum. It should also agree with the balance of "raw material" account on the general books.

### Time Reports

Each employee engaged in productive labor is required to report his time each day on a daily time report, showing the number of hours consumed on each order number (see Form 4). This report is checked by the foreman and passed to the accounting department.

When these time reports get to the accounting department they contain merely the employee's number, the number of hours employed on respective order numbers, and the date. The time clerk will then extend the cost of labor expended upon each, and all reports relating to the same number are collected and the number of hours and cost thereof on a labor distribution sheet (see Form 5).

At the end of each paying period this sheet is totalled, and should, of course, equal the amount of the pay-roll, which is posted directly from the time reports. This makes one of the best possible checks on the pay-roll. In the general ledger, manufacturing is debited and accrued labor is credited. This will always keep a credit balance to accrued labor, except on the day on which the

| DATE | ORDER No 1 | | ORDER No 2 | | ORDER No 3 | |
|---|---|---|---|---|---|---|
| | HOURS | AMOUNT | HOURS | AMOUNT | HOURS | AMOUNT |
| TOTALS | | | | | | |
| L.F. | | | | | | |

FORM 5 ALLOCATION OF TIME COSTS TO PROPER WORK ORDERS.

pay-roll is paid, and even then in cases where payment is not made up to date. The cost of the productive labor expended on each order number is then posted to the debit of the respective order accounts in the cost ledger from the summary sheet.

### Incidental Expense Reports

In order to ascertain correctly the general expense, it must always be remembered that the labor expended upon the reports is always non-productive. The orders or units against which all general expenses are charged are, in every instance, standing orders. The material is ascertained usually in the same way as outlined above for material in general, but there is apt to be a deviation from the rule that the storekeeper receive and issue all materials. It is sometimes necessary that the supplies be first consumed and then a report made as to the order numbers against which they should be charged. This often occurs in the consumption of very small lots of inexpensive supplies, such as coal, etc. A summary sheet of materials consumed is shown in Form 6.

The time expended under manufacturing expenses is reported in the same manner as that expended by productive labor, except that no record is kept of the number of hours expended.

| ACCOUNT | AMOUNT | ORDER No | HOURS | RATE | EXTENSION | L.F. |
|---|---|---|---|---|---|---|
| | | | | | | |
| TOTALS | | | | | | |

FORM 7. DISTRIBUTION SHEET OF MANUFACTURING EXPENSES

Having charged to each account in the manufacturing ledger the expenses pertaining to it, the next step is to distribute them over the various orders for the production of goods as shown in the cost ledger. This distribution is made by means of a distribution sheet of manufacturing expenses (see Form 7).

In the account column is placed the name of each account appearing in the manufacturing ledger, and in the amount column the total expended under the account. In the order number column are placed the numbers of all the orders worked on for the period, taken from the cost ledger, and in the next column is placed the number of hours of productive labor expended on each such order number. The total of this number of hours divided by the total amount expended as given in the amount column gives the unit rate or constant by which the total amount of the manufacturing expenses is thus properly distributed, and is ready for transfer to the proper accounts on the cost sheet. This distribution is made at the end of each period.

### Closing of Completed Order Numbers

When the articles to be manufactured by an order are completed, that order number is ended and the account in the cost ledger must be closed. To do this a summary sheet of order numbers completed is prepared for each given period (see Form 8. This is the medium through which is completed the transfer from goods in process of manufacture to finished product.

### The Main and Auxiliary Ledgers

In addition to the main or general ledger, there are four auxiliary ledgers maintained, each of which has a controlling account in the main ledger. These are: Stores Ledger, Cost Ledger, Creditors' Ledger, Manufacturing Ledger.

The account in the main ledger is manufacturing, which is the controlling account for the cost ledger. This account is debited with the total account of material drawn from stores, accrued labor, and accrued manufacturing expenses.

| DATE | ORDER Nos | FINISHED PRODUCTS | |
|---|---|---|---|
| | | SALES | STOCK |
| | | | |
| TOTALS | | | |
| L.F. | | | |

FORM 8. SUMMARY SHEET OF ORDER NUMBERS COMPLETED

The auxiliary ledgers are self-explanatory. The stores ledger is a record of stock received and issued. The total purchased is carried to the main ledger through the summary sheet of goods received.

The summary sheet of orders completed is posted in detail to the credit of respective completed orders in the cost ledger, there being no debit, this being but a transfer of completed orders from the cost ledger to the summary sheet. The summary entry on this sheet is posted in the main ledger to the debit of finished product and to the credit of manufacturing.

When this transfer of cost totals for the month to the general books account has been made, there remains but little to be done to complete a monthly statement of the results of operating and trading. The figures presented are not the results of estimates but of actual operations, and, if the accounts have been well and carefully kept, are not of less value because of being presented at the end of the month, instead of at the end of twelve months. Monthly statements of operating and trading are of the greatest value.

In these days of immense transactions, quick trading, close margins and frequent incident of risk, yearly statements showing the results of operating and trading are largely matters of past history. Something more than this is required for the wide-awake business man. In a fiscal year a concern may suffer serious loss, or let pass the opportunity to engage in profitable manufacturing because of the absence of immediate information which modern methods of accounting would afford. Once a complete system is installed the issue of frequent statements is a matter of comparative ease, with the result that the company is at all times thoroughly in touch with every phase of its affairs.

## UNITED STATES MACHINERY AND TOOL BUILDERS' WAR CONVENTION AT CLEVELAND

Cleveland committees which are working ply industry the largest in the histories of the various organizations which will

To consider ways and means of keeping the supply and machinery industry and decisive conclusion will be the work of the convention. During the week of May 13 the Hollenden Hotel, Cleveland, Monday and Tuesday, May 13 and 14, the National Pipe and Supplies Association will meet. Wednesday, Thursday and Friday, May 15, 16 and 17, there

HOTEL HOLLENDER, CLEVELAND, WHERE CONVENTION IS TO BE HELD

will be a joint convention of the National Supply & Machinery Dealers' Association, the Southern Supply & Machinery Dealers' Association and the American Supply and Machinery Manufacturers' Association.

R. F. Valentine, of Cleveland, president of the American Supply & Machinery Manufacturers' Association, has been named the chairman of the Cleveland committees. W. M. Pattison, general chairman, is past president both of the National Supply & Machinery Dealers' Association and the National Pipe & Supplies Association. Mr. Pattison is a member of the Stores Division of the Council of National Defence, and is one of the most active civilian aides of the Ordnance Department in the present emergency. H. W. Strong, chairman of publicity, is president of the National Supply & Machinery Dealers' Association, and was one of its organizers.

D. K. Swartout, chairman of the press committee, is past president of the American Supply & Machinery Manufacturers' Association. H. E. Dickerman, chairman of the decorations committee, is also past president of the American Supply & Machinery Manufacturers' Association. S. D. Latty, of the Kirk-Latty Mfg. Co., is chairman of the entertainment committee. George M. North, of the Ferry Cap & Set Screw Co., is chairman of the finance committee. H. C McKean, of the Standard Tool Co., is chairman of the ladies' entertainment committee. F. H. McIsaac, of the Kirk Latty Mfg. Co., is secretary of the convention, and Harold D. North, of the Ferry Cap & Set Screw Co., is treasurer.

At the Wednesday session addresses will be given by the presidents of the associations represented and reports and discussions on business methods will take place.

Papers will be read by representative manufacturers on the business situation as affecting their various lines on Thursday and addresses on the supply and machinery man's part in winning the war will be given. Friday will be given over to executive sessions and discussions on sales problems.

It is expected that a national speaker will be present to give an address dealing with the machinery and supply trade as relating to the war.

## NAVIGATION OPENING ADJUSTS EXCHANGE

CANADIAN financiers expect the exchange situation to become more normal now that lake navigation has opened. Vast stores of Canadian grain ore and merchandise have lain in the holds of vessels, warehouses and granaries throughout the winter months awaiting the going out of the ice. These stores of goods will now be delivered in American ports as rapidly as Canadian wooden and steel freighters can carry them there.

Steamship companies look for the most active freighting season ever experienced on the Great Lakes. Not only have several new vessels been put into commission, but many old vessels have been completely overhauled and put back into service. In addition to this the holds of most passenger steamers have been enlarged, and all but a few passenger vessels will also carry package freight. Authoritative figures show that actual lake tonnage will be considerably greater than a twelve-month ago, despite the taking over for war purposes of a number of fresh water boats.

Exchange statistics show that soon after the opening of navigation last year there was a sharp decline in Canadian funds of New York, and that after shipment of Canadian goods had been going forward by water for about a week, par was reached and from then on the exchange rate ruled more favorably for Canada. At the present time the rate for us is much more unfavorable than a year ago, as the balance of trade is preponderatingly in favor of the United States. So that even with increased shipments of Canadian goods it may take longer for a rate favorable to Canada to be reached. But the Canadian restriction of imports recently decided upon is also a considerable factor which will materially assist in reducing the balance of trade now against Canada.

## CANADA BUYING ROLLING STOCK

CANADIAN car builders will require about 80,000 tons of steel bars, plates and shapes for the construction of cars, and 30,000 tons of cast rolled and forged steel for building locomotives, orders for which have been placed with equipment manufacturers in the last few weeks. This steel tonnage is probably a part of the 700,000 tons reported on order with American mills for shipment to Canada. In addition to the 6,400 cars placed with the Canadian car builders a few weeks ago, the Dominion Government has ordered from American manufacturers 1,721 cars, including tanks, refrigerators, side and centre dump cars and cars for passenger service. The total expenditure of the Canadian Government for cars and locomotives will be $32,966,515, of which $23,759,435 is for car construction alone. Some additional orders for cars and motive power may be placed in the near future.

THE Shanghai electric power station continues to suffer from the defective working of the German machines, says "Eastern Engineering." A recent report by the acting engineer-in-chief and manager, Mr. A. H. Blagden, shows that further serious breakdowns have occurred, with the result that in November of last year the whole of the 14,000 kilowatts of A.E.G. plant was out of commission. It was impossible to effect all the repairs locally, and it is questionable even when the repairs have been made that the results will be satisfactory. It is significant that this failure of German electrical machinery has also occurred in such widely distant countries as South Africa and Australia, so that the breakdown in China is not an isolated or exceptional case. It is equally significant that the British machinery at Shanghai has stood the test of time, and has in every way proved itself superior to the A.E.G. plant.

## TEST PIECES FOR MATERIAL COMING UNDER SUPERVISION OF LLOYD'S REGISTER

By A. F. Menzies.

METHODS and procedures for the accurate testing of materials have assumed great importance in the last three years, consequent upon the expansion in all metal working industries necessitated by the insatiable demands of modern warfare. The impetus given to shipbuilding by the inroads of the submarine and the increased volume of traffic handled has resulted in a widespread demand for knowledge of matters relating to design and construction and the testing of materials entering into ship construction is of considerable interest at the present moment.

Material entering into the construction of ships coming under the supervision of Lloyd's Register of Shipping, is subject to test and the test-pieces illustrated in this article have been standardized by a Canadian plant for their own convenience. Since considerable time can be wasted in the looking up of specifications and requirements for the test-pieces used, tabulated drawings were prepared in such a manner that all the dimensions required by Lloyd's and those governed by the design of the machine were readily accessible together with the requirements which had to be met by the test-pieces under load. By this means the information was always available and the making of rough sketches was obviated.

Fig. 4 shows the test-pieces required for the tensile proving of plates and shapes. The elongation required in the table applies to material ⅜ inch thick and over. For ship-material less than 5/16 inch thick the requirements as regards elongation are slightly smaller, the minimum elongation necessary being 16 per cent. For boiler plate the elongation of material less than ⅜ inch thick may be not more than 3 per cent. below the tabulated values.

The cold and temper bend test piece for plates and shapes is shown in the upper view of Fig. 2 and for cold and temper bends the test piece must withstand bending double on itself, the maximum allowable internal radius being 1½ times the thickness of the test piece.

The tensile test pieces for bars are shown in Fig. 3. Test piece B is used for bars one inch or less in diameter and C for bars over one inch. Test piece B may be used for bars over one inch in diameter provided that the diameter of the gauge length is turned down to one inch or less diameter.

For steel castings and forgings the test pieces, shown in Fig. 4, are threaded. This enables a shorter over all piece to be used and economizes in material. The third piece would have required an 1½ inch thread which would have been too large for the jaws of the testing machine. This piece is therefore shown with a square end, which also enables a shorter grip to be taken than if the piece were cylindrical.

The bend test pieces for steel forgings and castings are shown in the lower part of Fig. 2. The test piece for steel castings must withstand without fracture being bent cold through an angle of 120°, the internal radius being not greater than one inch.

The bend test piece for steel forgings must withstand being bent cold through an angle of 180° without fracture, the internal radius being not greater than ¼ inch.

FIG. 2.—UPPER COLD AND TEMPER BEND TEST PIECE FOR PLATES AND SHAPES. LOWER BEND TEST PIECE FOR STEEL CASTINGS AND FORGINGS.

**Cold and Temper Bend Tests For Plates and Shapes**

In a cold bend test and in temper bend tests for plates and shapes [illegible] 1 in. in thickness the rough edge may be removed by filing or grinding. In samples 1 in. in thickness or over the edges may be machined. For both cold and temper bends the test piece shall withstand, without fracture, being doubled over until the internal piece and the sides are parallel.

**Bend Test Steel Castings and Forgings.**

For steel castings the test piece must withstand without fracture, being bent cold through an angle of 120° the internal radius being not greater than 1 in.

For steel forgings the test piece must withstand, without fraction, being bent cold through an agle of 180é the internal radius being not greater than ¼ in.

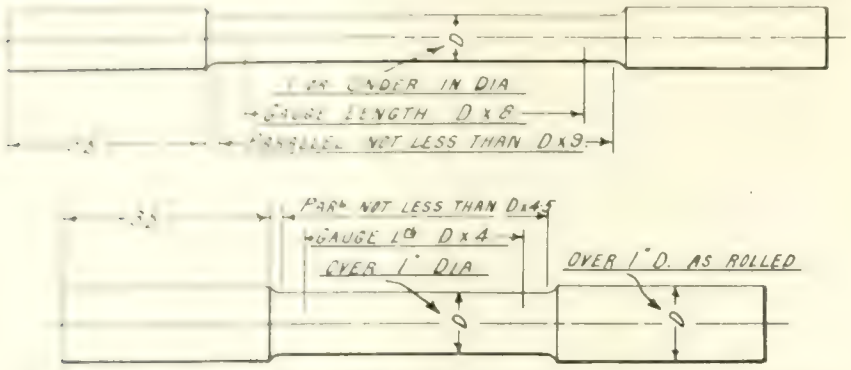
## BRITISH SHIPBUILDING ACTIVITY

NEVER has there been greater activity in the shipbuilding yards of GGreat Britain than exists at present. On the four principal shipbuilding rivers of the British Isles every available foot of adjoining land has a ship more or less in construction on it. Nearby engine works are turning out motive power for the vessels at a tremendous rate. Shipbuilders of various sorts—men, women, boys, girls—are all working at top speed. Great Britain has two great objects in all this activity. The first is to help to beat the German U-boat destructiveness and the second is to recoup her greatly theatened prestige as the first maritime nation of the world.

Nowhere is the growing importance of the United States and Japan as maritime



UPPER, TENSILE TEST PIECE B FOR BARS. LOWER TENSILE TEST PIECE C FOR BARS.

Note: Test piece B may be used for any dia. bar provided gauge length is turned to less

| | Tensile Strength | Elongation B | Elongation C |

| Combination Chamber Stays | 28-32 tons | 20% | 24% |
| | 26-30 tons | 23% | 28% |
| | 26-30 tons | 25% | 30% |
| | 25-30 tons | 25% | 30% |

assume their maritime precedence, and the British navy, which has been kept intact during the war, will enable authority to be given to these demands. It is well known in America that British builders are rushing out countless destroyers, cruisers and other naval ships, which must for the present remain as "mysteries." Standardization of construction has been adopted in the shipbuilding yards to the greatest possible extent. All parts of hulls, engines—in fact everything—are standard and may be used where first needed. Hitherto thirty-five sizes of steel sections were used in the construction of ordinary vessels, and standardization process has reduced the number to eight. Before the war Germany was the only real competitor on the sea and now there are two—friendly may be, but nevertheless competitors—Japan and the United States.

## REGULATION OF IMPORTS

In its commercial letter for the month of April, the Canadian Bank of Commerce takes it for granted that some regulation of imports will become necessary, and asserts that Canadians as a people are not economizing to the extent that is desirable. The letter says:

"The War Trade Board is contemplating the adoption of some decisive steps to regulate the importation of non-essential commodities, but the precise nature of these steps has not yet been announced. The object will doubtless be to reduce our imports from the United States, with a view to conserving our financial resources for war objects and to placing exchange conditions on a more satisfactory basis. Some lines of business may by this action be temporarily dislocated, but the capital and labor employed therein might be diverted to other forms of enterprise with ad-

funds indicates the continued existence of a considerable adverse balance of trade, which is partially created by the importation of non-essential articles.

"Public men, realizing how imperatively necessary it is that the resources of the country should be conserved in every possible way, continue to urge economy and co-operation with the departments of the government established for that purpose, but it is quite obvious that the general public is not depriving itself of its usual comforts and luxuries, despite the continually advancing prices of all necessaries. The abundance of employment at high and advancing wages, due to war conditions, is sustaining the present apparent prosperity, which, as might be expected, is not accompanied by evidences of personal sacrifice and frugality. Our railroad, financial and industrial organizations are working at very high pressure, and on the whole have, since the outbreak of the war, developed greater efficiency. The output of our industries continues to increase, and more orders are being placed here by the Government of the United States. It remains highly desirable, however, that industries necessary for the successful prosecution of the war should not be hampered by lack of labor and should have the sympathetic co-operation of Government agencies. The producers and importers of commodities not of this class may, however, reasonably expect to have their operations curtailed, and any effort to this end on the part of the War Trade Board will be welcomed by all who realize the seriousness of the outlook."

THE larger part of the antimony shipped from Hankow, China, comes from the province of Hunan; only a very small part of it is smelted in local furnaces. The trade is largely in the hands of Japanese firms.

The addition of small quantities of molybdenum and chromium to iron by an experimenter in Europe has produced a practically acid proof alloy.

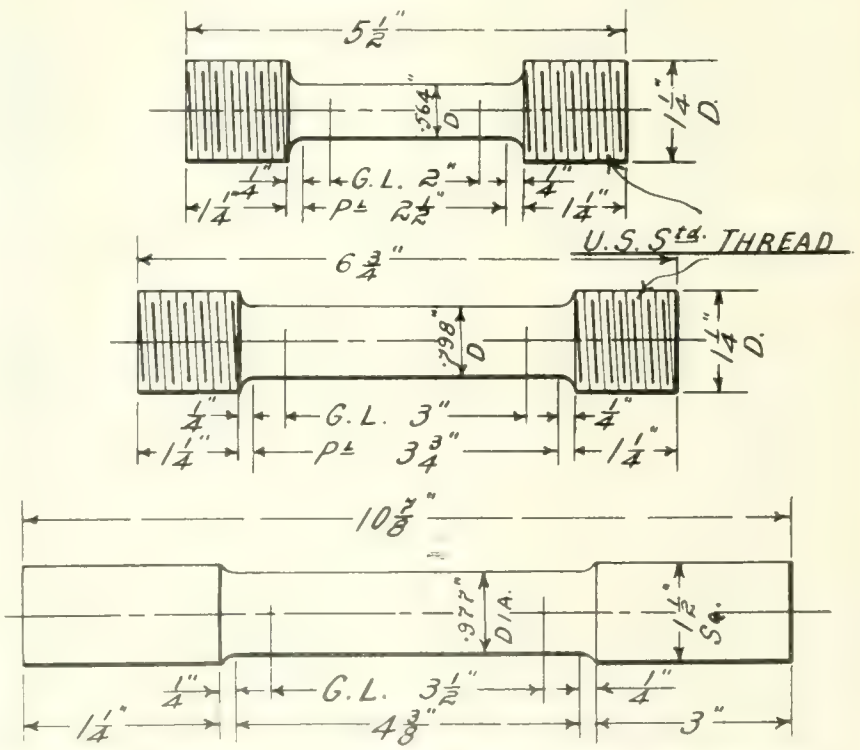

FIG. 4. TENSILE TEST PIECES FOR STEEL CASTINGS AND FORGINGS.

| TABLE 3. | Tensile Strength | Elongation |
|---|---|---|
| Steel Castings | 26-35 tons | 20% |
| Forgings | 28-32 tons | 29% for 28 tons T<br>25% for 32 tons T. |

In no case must the sum of the tensile strength and elongation be less than 57 for steel forgings

# Worm Gearing: Principles of Design and Manufacture III*

By Francis J. Bostock

*For many years the manufacture of worm gears was undertaken by means of empirical and more or less rule of thumb methods and as a consequence efficiencies were low and unsatisfactory. Improved methods of design and manufacture in recent years have effected such improvements that the worm gear is to-day one of the most efficient methods of power transmission. Considerable interest attaches to the description by the writer of the various machines and methods used in the production of worm gears.*

### Worm Thread Grinding

IT has been mentioned that it has been necessary to design special machines for each individual operation. The various movements to be executed in the grinding of a multi-threaded worm are intricate and require to be carried out with the greatest precision. The ideal machine should, of course, be automatic in action, but the designing of a machine to fulfil such stringent conditions is a most difficult proposition; nevertheless it has been accomplished, with entirely successful results.

The general lines of this machine are based on the best modern practice of up-to-date cylindrical grinders, as will be noted in Fig. 11. The abrasive wheel is mounted upon a universal head, and is of large diameter, its shape being generated by a patent diamond generating device. The wheel is so mounted that it can be easily placed in the best position relative to the thread of the worm, with regard to the spiral and pressure angles, thus enabling a large diameter to be used without interference. The worm is caused to travel spirally in front of the wheel; the change gears, in order to give the necessary lead and index, are situated respectively at the top and side of the fixed head, and the motion, after rotating the work, passes through the lead change gears and the differential, so driving the lead screw nut, thus giving the necessary spiral movement. During the cutting operation the motion passes through a gear-box to give various grinding speeds, but for the quick return the drive is taken direct; and the mechanism is so connected to the abrasive wheel slide that at the moment of reversal for the return stroke the latter is rapidly withdrawn from the work, and at the end of its travel it slowly approaches the worm thread, ready for the next cut. During the quick return stroke the differential comes into action and causes the worm to be automatically indexed to the next thread.

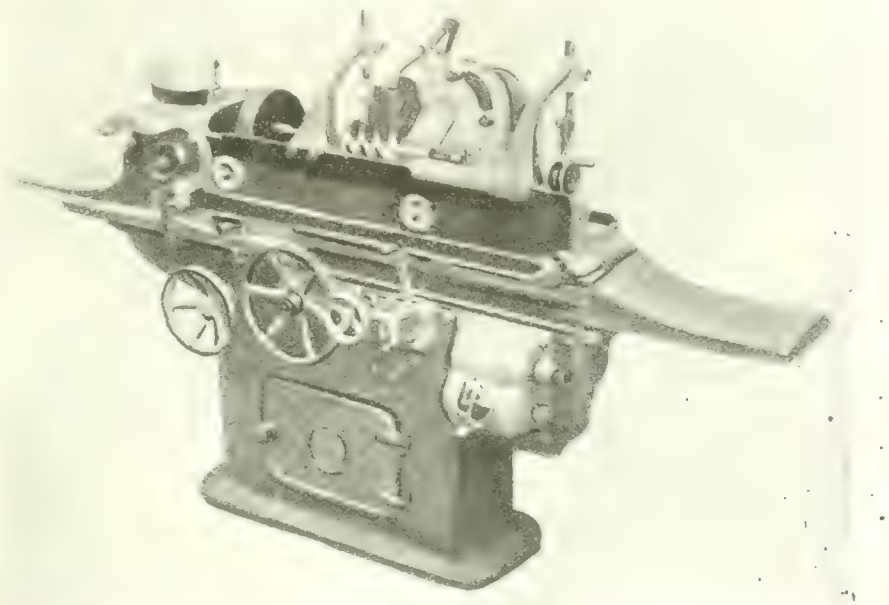

FIG. 11. WORM GRINDING MACHINE WITH ITS MEASURING INSTRUMENTS.

The machine is so designed that the worm is revolved on fixed centres, the top table being also pivoted to provide for the correction of parallelism. An easy movement of the handles gives instant setting to suit either a right or left-hand worm. The whole of the operating hand wheels and levers are situated in front of the machine in a most accessible position. The simple movement of a lever automatically arrests, at the end of the next quick return stroke, all the movements of the machine, thus enabling the operator to gauge the work that is being ground. After gauging, the machine is ready to commence the next cutting stroke, it being only necessary again to move the above lever, when the cycle of operations is once more resumed.

### Generated Grinding Wheel Curves

One has already observed how it is necessary for the worm-milling cutter to have its contour generated, and when this is with a cutter diameter of only 5 in. how much more so is it not imperative

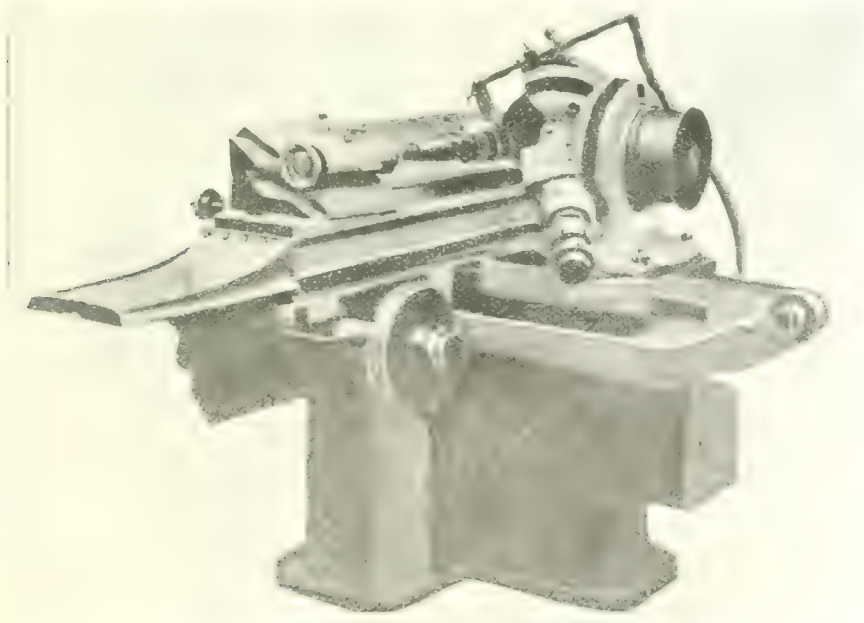

FIG. 11A. ANOTHER VIEW OF WORM GRINDING MACHINE.

*Read before the Manchester Association of Engineers.

FIG. [illegible] WORM GRINDING ABRASIVE WHEEL GENERATOR

[illegible] which carries a reciprocating diamond set to travel at the required pressure angle and situated exactly upon the centre line of the system; hence it follows that its movement corresponds to a line on the worm face, so that when it is caused to reciprocate at the same time as it traverses spirally across the face of the wheel, it will give to the latter just that particular shape which will in turn grind the worm with the correct shape of tooth.

The work is fed laterally to the face of the wheel, hence the contour remains constant during the grinding operation. After one side has been done the worm is turned end for end, and the other side ground in like manner. The machine is fitted with measuring devices for the [illegible] of the work during grinding operations.

### Manufacturing and Sharpening of Hobs

The teeth of worm wheels are of such construction that they do not lend themselves to operations of planing, shaping or milling [illegible] forms of gearing, and can only be produced by a process of generation by means of a cutting tool called a hob.

At first the hob would appear to be a reproduction of the worm, with which the wheel will have to mesh. Whilst it is true that the spiral angle, pitch, number of threads, and pitch diameter must correspond exactly with that of the worm, yet both the outside and bottom diameters are made larger in order to provide requisite clearance in the roots of the teeth. There is a still further difference in that the hob thread is gashed along its length normal to the spiral angle for the purpose of providing a cutting face, whilst the sides of the teeth are relieved in order to provide a cutting clearance.

As the shape and contour of the wheel teeth are entirely dependent upon the design and accuracy of the hob, it is necessary that this tool should receive the most careful supervision in all the stages of its progress, because when finished it is extremely difficult to examine it without cutting a wheel, and so verifying the shape by means of a worm. No matter how perfectly one may make a hob, unless it be sharpened with a corresponding degree of accuracy and precision the original object is quickly defeated, rendering it useless for first-class production. It has therefore been found necessaryy to design and build a special machine for the purpose of sharpening hobs and cutters.

The general lines of this machine will be apparent from Fig. 13. It consists essentially of a column carrying a ram slide, the latter carrying, at right angles, the abrasive wheel slide. The hob or cutter to be ground is mounted vertically on a suitable holder, which is centrally situated in a circular water basin, which in turn is fitted to the bed of the machine. The abrasive wheel is mounted upon a universal head, which can be rotated at an angle to suit the lead of the gashes of the hob, and is driven from an overhead countershaft by means of round leather belting.

The ram slide is reciprocated in a vertical direction, thus causing the abrasive wheel to traverse the length of the hob, the latter having given to it by means of change gears the requisite rotation to give the required spiral movement. The machine is so designed that the return stroke is at a higher velocity than the cutting one, and the depression of the operating pedal causes it to stop at the top of its next up or return stroke. The indexing is accomplished by means of a dividing plate, in conjunction with which is a fine adjustment for obtaining the feed or cut.

Hobs are generally made with their cutting faces radial; it is therefore necessary that they be sharpened radially, or an alteration in shape will result. The same, of course applies to ordinary rotary cutters. In order to accomplish this an abrasive wheel generator is placed in the machine instead of the hob. In this generator the diamond reciprocates radially, so that when it traverses the face of the abrasive wheel it removes that interference which would prevent the wheel from cutting a radial face. This interference is very great, and the resultant shape is a peculiar curve which varies with every hob, position and diameter of wheel.

It will be readily seen that as a hob is sharpened its diameter is reduced, but with a reamer hob the reduction in diameter is only a few thousandths of an inch in the whole length of the tooth; thus uniformity of shape is obtained. Most of the hobs are made from high-speed steel, many of which are ground on the threads after hardening.

### Worm Wheel Generating

Generally the worm wheels are rough-turned on automatics and turret machines, and pass from thence to the worm-wheel section for rough cutting of the teeth, after which they are finish-turned, and finally the teeth undergo a reamering or finishing operation. In no small measure is the interchangeability and high efficiency of the wheels due to this reamering operation.

The generating of the teeth of the worm wheel is carried out in a machine as illustrated in Fig. 14, the blank being mounted upon a revolving table, which is positively driven at a predetermined speed, according to the ratio of the gears being cut, whilst the hob is caused to travel longitudionally across the face of the wheel. Owing to the spiral of the hob it is necessary to compensate for its longitudinal travel by means of a differential, whilst the rate of travel or feed can be varied at the will of the operator.

A special feature is made of the mounting of the worm wheel on the table. A hardened and ground micrometer adapter carries the arbor, which supports various other adaptors to suit the locating register of the worm wheel blanks, the micrometer being adjusted until the specified distance from the locating face of the blank to the axis of the hob is obtained.

To facilitate setting up, and to test the true running of the registers and worm wheel blank, the drive to the table

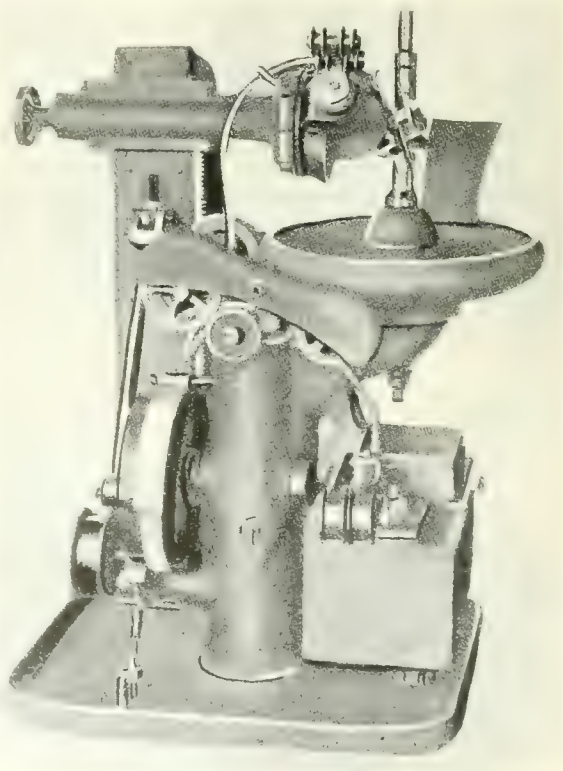

FIG 13 SEMI-AUTOMATIC HOB SHARPENING MACHINE WITH QUICK RETURN MOTION TO GRINDING HEAD.

is arranged so that it can be disconnected in order that the operator may be able to revolve the table by hand and so, by means of a clock indicator, test the accuracy of the mounting.

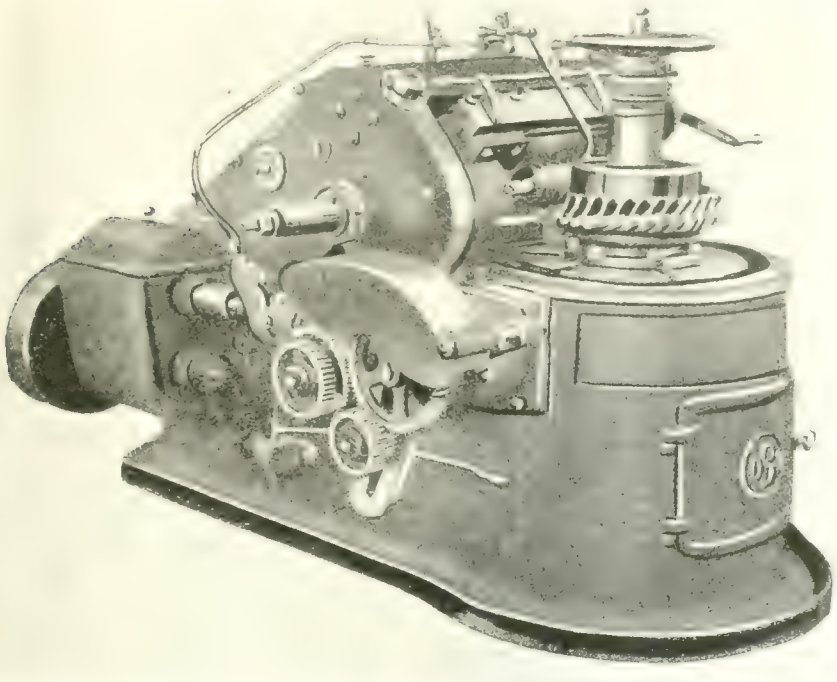

FIG. 14. WORM WHEEL GENERATING MACHINE WITH SPIRAL HOB MOVING LONGITUDINALLY TO INCREASE DEPTH OF CUT.

The head, which slides horizontally along the bed towards the worm wheel, contains the whole of the mechanism for driving the hob and traversing the hob slide. The latter is mounted on the head at an angle normal to the direction of the stress, so as to present the maximum bearing area to the very best advantage.

The main drive is taken from a single pulley fitted with an internal friction clutch in conjunction with a four-speed gear-box. The drive is then transmitted in one case directly to the index change wheels for driving the table, and in the other to the worm wheel mounted on the hob spindle.

It should be mentioned that the dividing wheel is of greater diameter than the largest blank which the machine will cut, and a neat design is effected by allowing the cuttings to fall through the arms of the table into the bed of the machine, from whence the cutting lubricant is drained.

### Inspection and Testing

Interchangeability of the worm wheel is ensured by the use of a double ball micrometer, which measures the comparative pitch diameters.

The final inspection is made on the testing machine shown in Fig. 15, where the work undergoes a more rigorous test. The wheels are tested for concentricity of cutting and the distance from the centre of the worm axis to the locating face, after which they are tested together to verify the centre distance. From the foregoing it will be realized that the system of manufacture and inspection described enables the worm and [illegible] wheels to be regarded as independent components, hence facilitating production and duplication.

Turning now to the application of worm gearing: in many cases the contracts for reducing gear units specify that prior to despatch they shall undergo to the satisfaction of their engineer running tests as near as possible to the actual service conditions, during which [illegible] various observations and readings are taken to determine the satisfactory running of the gears.

Some time ago, in order to ascertain the efficiency of a worm-driven back axle as a unit, a series of tests were made on a chassis which was in the course of erection. The carden shaft was replaced by an Amsler torsional dynamometer, the differential was locked, the chassis jacked up, and a special prony brake was applied to one of the rear wheels. The resulting efficiencies at different speeds and loads varied from 94 per cent. to 96 per cent. The result included the loss in friction by the universal joint, journals and thrust races, felt washers, the air resistance of the spokes and felloes of the wheels, in fact as near as possible to the actual road conditions. When it is remarked that this worm and wheel had been assembled exactly as they came from the machine shop, it shows conclusively that, with the method and degree of accuracy obtained by the processes described, the high efficiency is attained right at the commencement, the net efficiency of this gear being within the region of 96 per cent. to 98 per cent.

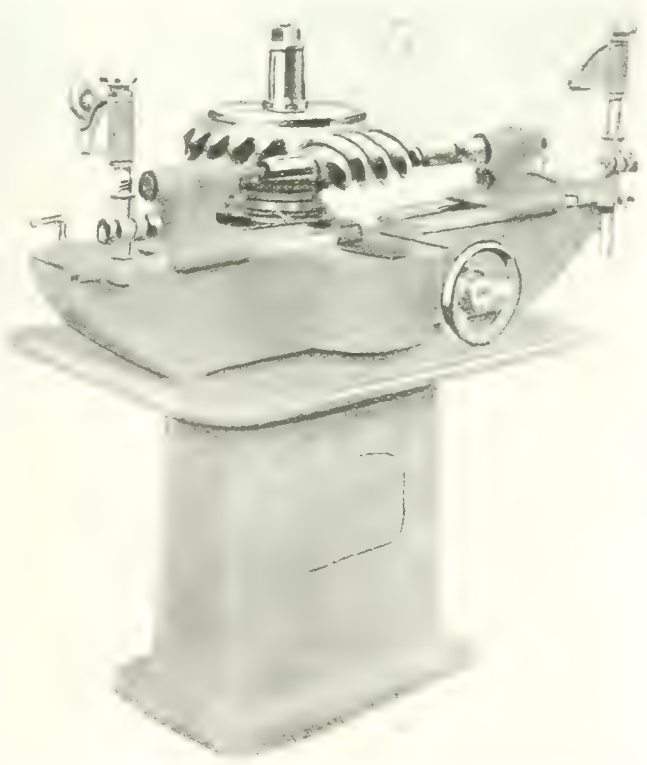

FIG. 15. MACHINE FOR TESTING CONCENTRICITY OF CUTTING, DISTANCE FROM CENTRE OF WORM AXIS TO LOCATING FACE AND ALSO CHECKING THE WORM AND GEAR TOGETHER.

### Worm Gear Application

Worm reducing gear units are with great advantage coupled direct to electric motors, enabling reductions in speed from 4: 1 to 100: 1 in a silent and efficient manner, and when both of them are mounted on the common baseplate they represent a simple, sound and economical proposition. For shop drives, machine tools, boiler feed pump, blower, and other work they have proved themselves to be invaluable.

On account of their ability to withstand considerable overload for short periods they lend themselves admirably to intermittent work, because for the work they are called upon to do they can be made relatively small; therefore they are of great use in crane work and for starting purposes of electric motors, steam, gas and oil engines.

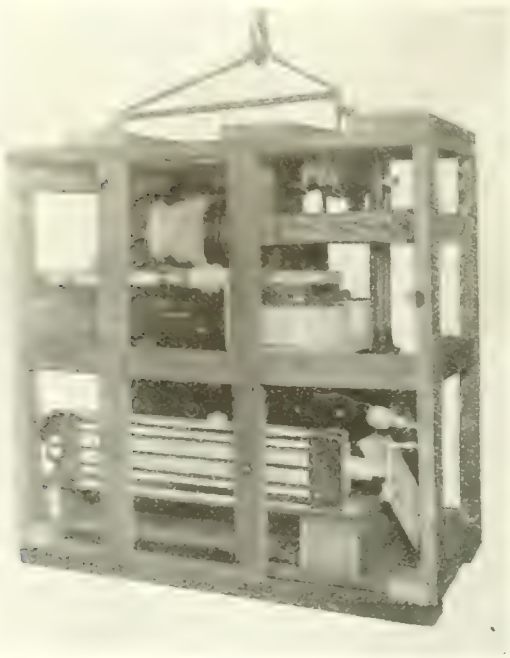
placing at his disposal the facilities for the reading of this paper.

### CRATING MACHINERY FOR EXPORT

As a result of the development of the machinery export [illegible] a packing case manufactured and used by the Ford-Smith Maching Co., of Hamilton, for shipping their machine tools to Europe, [illegible] parts of the world. Former experience in the export trade made the company realize the necessity and obvious advantage of providing a strong and not too cumbersome packing case for this particular purpose. The ordinary method of packing machinery was found to be unsuitable for the hard usage meted out to shipments going abroad particularly at this time when skilled stevedores and laborers are scarce. The possibility of having machinery broken in transit, occasioning delays and other inconveniences, was too serious because of the necessity of the shipment reaching its destination intact, as soon as possible, as machinery exported now is required for work [illegible].

The Ford-Smith Machine Co. are making a new line of plain and universal machines in addition to grinders of various types. The demand for this product developed to such an extent that for the European and foreign mar[illegible] a special packing case for export shipments alone. The description of the crate, which in this particular case was made for shipping milling machines, will doubtless be of service to other [illegible].

The illustrations show the packing case with the outside boarding removed in order to give a better idea of its general construction. The case is made of substantial lumber which was found to be absolutely necessary in order to stand rough handling in transit. The case which is compact and rigid measures 5 ft. 5 in. x 5 ft. 4½ in. x 2 ft. 7¾ in., and is entirely enclosed with 1 in. x 10¼ in. boards, all being dressed on the outside. The top of the case is composed of 2 in x 10 in. boards also dressed on the outside. The bottom skids for the No. 2 size millers are made from 5 in. x 4 in. hard maple, while for the No. 3 size machine 6 in. x 4 in. hard maple skids are used. The uprights are 2 in. x 4 in. and 2 in. x 5 in., well braced at important points. The main members are bolted. At the corners band iron straps, bolted through the main members, are used to further stiffen the crate.



GENERAL VIEW OF MILLING MACHINE PACKED FOR EXPORT.

END VIEW OF MILLING MACHINE PACKED FOR EXPORT.

Two lifting rings or slings made of round iron are used when lifting with a crane. The slings are put round the arm of the machine, which is protected with bagging, and pass through slots in the top of the crate when required for lifting, otherwise they are not exposed. This is not the least important factor in the make-up of the case, as the crane lifts the machine direct, avoiding undue strains on the packing case and also facilitating handling during transit.

The boards and skids are all cut to specification and assembled to drawings, ensuring all crates being of equal size and strength, and materially lowering production costs. The box fastened to skids at the bottom contains the arbors, handles and miscellaneous equipment, at the same time acting as a rest for the miller table. The countershaft pulleys rest on stiff bracing at the top of knee, while the countershaft proper is well supported by two special blocks shaped for the purpose.

### GEAR MANUFACTURERS MEET

THE second annual meeting of the American Gear Manufacturers' Association was held at White Sulphur Springs, West Va., April 18 to April 20. At the opening session on Thursday Mr. F. N. Sheppard, of the U.S. Chamber of Commerce, spoke on "How we can get behind the government and help win the war." Mr. B. F. Waterman presented a paper on gear standardization at the same session.

At the morning session on Friday, routine matters were disposed of, including the election of an executive committee and officers for the ensuing year as follows: For three years, F. W. Sinram, Cleveland; Frank D. Hamlin, Philadelphia; H. E. Eberhardt, Newark; for two years, Frank Burgess, Boston; Gee L. Markland Jr., Philadelphia; Milton Rupert, Pittsburg; for one year: Wm. Ganscou, Chicago; E. J. Frost, Jackson; H. W. Chopin, Syracuse.

The following officers were elected: President, F. W. Sinram; vice-president, H .E. Eberhardt; secretary and treasurer, Frank D. Hamlin. Friday afternoon was spent out of doors, the delegates amusing themselves as fancy dictated.

The annual dinner was held at the Greenbrier, Friday evening. Mr. John G. Willys and Mr. F. N. Sheppard spoke on this occasion. At the Saturday session two papers were presented as follows:

"Uniform Cost Accounting," by J. H. Dunn; "Hobbs and Hobbing Machines," by F. G. Hoffman and John Edgar.

About fifty members of the association were present.

The next meeting will be held in September, 1918, the exact time and place to be determined later.

### U. S. INLAND WATERWAY DEVELOPMENT

GREAT efforts are being made in the United States to improve the inland waterways throughout the whole country, and to increase the employment of motor barges, motor tugs, etc. There are many inland waterways in the country which are advocating the improvement, and the Inland Waterways Corporation of Louisiana and Texas at a recent meeting urged the construction of a canal, 9 ft. deep and 100 ft. wide, between New Orleans and Brownsville, which, it is stated, will shortly be put into execution.

A short time ago a convention was held of the Atlantic Deeper Waterways Association, when many improvements in inland waterways were suggested, and it was pointed out that these were needed, as the great railway system had almost broken down under the strain of increased traffic. Telegrams of approval were sent to the meeting by the Secretary of the Navy and also the Secretary of Commerce.

# Apparatus and Machines for Testing of Aeroplane Materials

*When it is realized that the aviator's life depends entirely upon the skill with which his machine is constructed and upon the soundness of the materials entering into its make-up, it is readily seen how important the testing of these materials becomes. The following article describes some of the machines used for this purpose.*

THE mastery of the air is possibly one of the factors which will influence the successful termination of the present war and the value which aeroplanes have for reconnaissance, bombing, artillery observation and fighting is so great that little need be said as to the necessity of outdistancing the enemy in their production.

It is not alone sufficient that aeroplanes be produced in greater numbers but they must also be of better design and higher efficiency than enemy machines employed for the same uses.

It is of interest in this connection to note some of the machines specially designed by Messrs. W. and T. Avery, Ltd., Soho Foundry, Birmingham, for use in aeroplane manufacture.

### The Balancing of Propellers

The device shown in Fig. 1 is a development arising out of the principles of static balance. A rocking bar with knife edges is mounted in bearings fixed to a substantial cast iron wall bracket. A spindle is mounted on this rocking arm in such a manner that the centre of the spindle is in line with the knife edges upon which the rocking bar is supported. A constant friction is thus obtained as well as an axial movement around the true centre of the propeller. On the spindle is mounted a gunmetal sleeve which fits the bored propeller boss. The sleeve is 8 inches long and has an attachment which allows it to turn on the spindle. This arrangement permits the turning of the propeller into different positions for balancing without disturbing the friction fit between the propeller and the gunmetal sleeve. The sleeve can be locked so that the propeller can be screwed on or off easily.

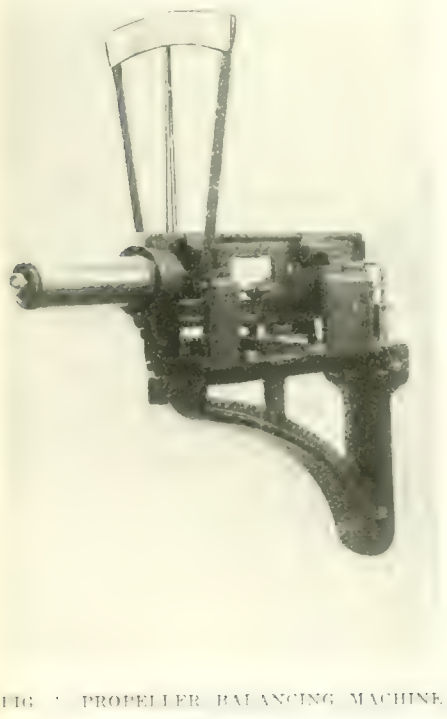


FIG. 1. PROPELLER BALANCING MACHINE.

A zero pointer and graduated chart are provided to indicate the quantitative errors in inch ounces, the minimum divisions being ½ inch ounce. These graduations show at once how near the propeller is balanced to the usual specification of ½ inch ounce error. The graduations are also useful in matching up the out of balance of laminations numerically before gluing. This process takes the place of matching heavy ends with light ones, and obtains a closer balance before this stage is reached. The graduations are of great assistance in the actual process of balancing, as with their use it is possible for the operator to gauge how much material must be removed.

The apparatus is controlled by a small dashpot placed at the rear of the rocking bar and so arranged that undue vibration of the propeller and the effects of draught are eliminated.

### Operation

When the machine has been installed it is adjusted by means of a small weight riding on a beam and moved by a key, until the pointer just returns to zero, when moved from the vertical. It does not affect the accuracy of the test if the pointer stops at a position slightly to either side of the zero mark.

When placing a propeller on the balancing machine the beam or rocking bar is locked by a slide and the propeller worked on to the sleeve by a to and fro motion.

### Balancing Two-Bladed Propellers

The propeller is first placed in a horizontal position. If the pointer swings beyond the graduations and against the stop the error is so large that plenty of material can be removed.

When the pointer shows the extent of the error in inch ounces then the excess weight can be estimated, if it is to be removed from the top of the blade, by knowing the distance from the tip to the centre. For instance, if the reading is 10 inch ounces and the distance from the tip to the centre is 48 inches then approximately ¼ ounce of material must be removed. If, however, the weight is to be removed uniformly over the blade, then the readings can not be converted into ounces but with practice the operator will know how much to remove for any design of propeller. As long as the excess weight can be removed by scraping, the propeller need not be removed from the machine and the gauging of the sections can be done quite easily.

FIG. 2. APPARATUS USED IN THE BALANCING OF CONNECTING RODS.

### Balancing Four-Bladed Propellers

In the balancing of four-bladed propellers two blades are placed in the horizontal position, the other two being in the vertical. The reading is taken and the horizontal blades now placed in the vertical position. The reading is again noted and it is readily seen which two blades are heavier than those opposing, the comparison of weight in each one being according to the difference in the readings. The balancing with the blades making angles of 45° to either the horizontal or the vertical can be done in a similar manner to the above, placing the propeller in two positions and making sure that the heavy part in the first position is located below the centre in the second to avoid unstable effects.

The polishing and varnishing of the propeller can be done as usual on the bench until the final coats are applied. The propeller is then placed upon the balancing machine and finished and balanced in position.

Hard and fast [illegible]

fers as to which part of a blade or blades the excess material is to be removed from. Some manufacturers take off excess weight from the tips or the flat face of the section according to the amount and to the gauging of the sections.

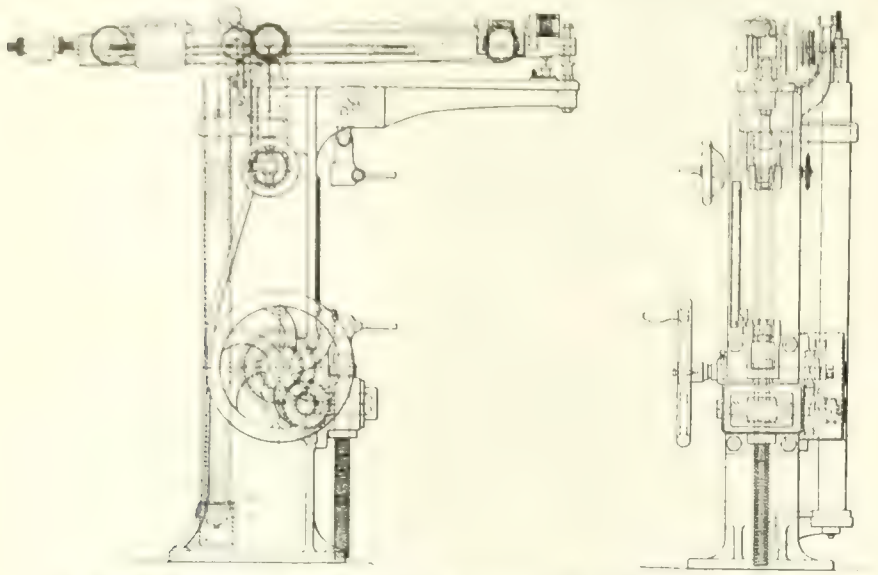

FIG. — AUTOPOISE WIRE-TESTING MACHINE OF 6,000 LB. CAPACITY.

With a four-bladed propeller it is not possible even by a process of elimination to determine that one blade is heavier than the other three, except at the initial stage of balancing, and it is more probable that the weight is distributed in two blades or portions of them.

Considering the rapidity with which balance varies, a tolerance of about one inch ounce might be allowed before polishing to be brought down to ½ inch ounce error in accordance with the specifications by means of the final polishing and varnishing.

A final check on the assembled propeller and steel holder or hub prevents any error creeping in, and for this a quantitive reading is most useful.

### The Balancing of Connecting Rods

On account of the high speed and delicacy of the aeroplane engine considerable care must be taken to eliminate vibration due to the faulty balance of the working parts. The connecting rods should be all of the same weight and also the distribution of the weight should be the same in all cases. Although the rods are machined all over variations in the density of materials and other causes frequently affect the centre of gravity of the rod.

With the machine illustrated in Fig. [illegible] to determine what correction, if any, is needed. A cast iron base plate, fitted with bevelling screws, carries the frames supporting the two steelyards shown. One of the frames can be adjusted to accommodate rods of different lengths.

In using the machine, a standard rod which should be somewhat lighter than those tested is suspended from the inner ends of the steelyards and the counterpoises adjusted until a perfect balance is obtained. This rod is then removed and replaced by the rod which is to be balanced, material being removed until both the weight and its distribution are the same as those of the standard rod.

It is necessary that all the rods should be suspended from the same centres and for this reason a short mandril having knife edges at each end along the axis is slipped into each end of the rod. These knife edges rest in stirrups suspended from the ends of the steelyards.

If desired, the steelyards can be graduated in ounces and provided with small poise weights which can be set to predetermined tolerances. Such tolerances are often used in specifications, and, in any case, the auxiliary poise weights form a convenient method of determining the exact amount of excess material to be removed.

### Tensile Strength Testing Machine

The many rods, wires, turnbuckles and shapes entering into the construction of aeroplanes are subjected to large stresses and the proper testing of these parts is very necessary.

The machine shown by the elevations and plan Fig. 3 forms a convenient piece of apparatus for this class of work, taking specimens up to ¼ inch, round or square, and flat specimens up to ⅞ inch wide by ⅛ inch thick.

The specimens may be of any length up to 12 inches between the grips and the maximum load that can be applied is in the neighborhood of 6,000 pounds. It will be seen that the machine is of the compound lever type, the levers being carried on a cast iron standard which also supports the straining gear.

The straining gear comprises a screw operated by means of a handwheel, and spur and worm gearing, all being enclosed in a cast iron housing.

A high speed gear is provided for the quick adjusting of the lower grips and this gear may be used for the testing of light wires where little power need be used.

### Indicating Arrangements

The extension of the specimen is indicated on a vertical scale graduated on nickel silver by means of an adjustable pointer fastened to the lower grips.

The main lever is an iron casting fitted with hardened steel knife edges and supported in hardened steel bearings. The upper grip is suspended from the middle knife edge of this lever as may be seen by reference to Fig. 3. The steelyard is an iron casting provided with hardened steel knife edges, the fulcrum knife edge resting in a bearing on top of the main standard while the rear knife edge carries a link to which the main lever is attached. The steel-

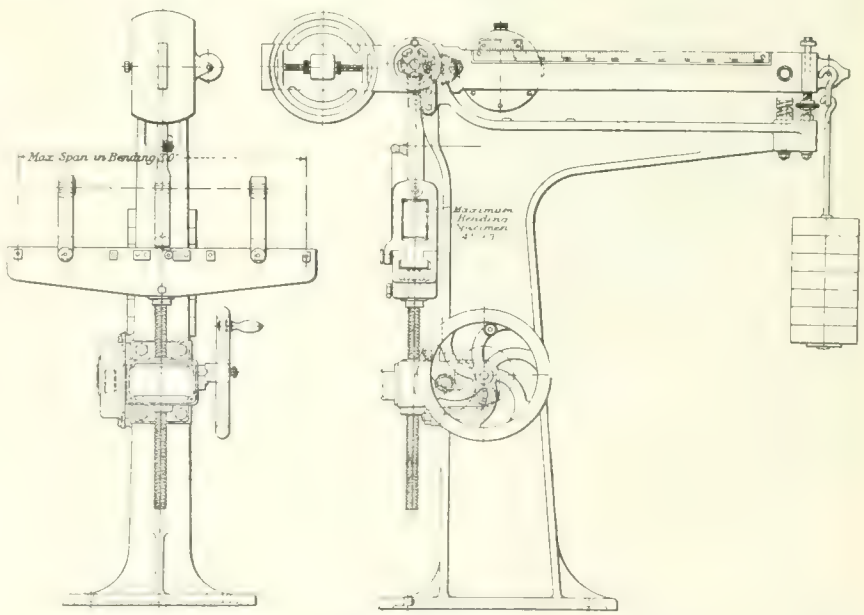

FIG. 4—10,000-LB. TESTING MACHINE ADAPTABLE TO A WIDE SCOPE OF WORK.

yard carries a scale graduated in steps of 20 pounds up to the full capacity of the machine, and the load at any moment during the course of a test is indicated by the position of the poise weight on this scale. A vernier attached to the poise enables the load to be read in single pounds. No loose weights are used.

The load is balanced by means of a very ingenious feature which automatically moves the poise along the arm as the load is applied. The poise mounted on rollers is propelled along a machined track on the steelyard by means of a falling weight enclosed in a tube filled with oil. The rate at which the load may be applied is varied by altering the viscosity of the oil. In making a test the operator has only to keep the straining wheel turning at such a rate that the steelyard is kept floating.

When the steelyard drops owing to the fracture of the test piece an electrical contact is made which automatically stops the movement of the poise.

Its position then gives an accurate record of the breaking load since there is no possibility of the movement of the poise continuing after fracture has taken place. There is therefore no need to watch the movement of the poise in tests which are only required to determine the breaking load. The small hand wheel near the top of the main standard, and visible in the illustrations, is for the purpose of returning the poise to the zero position at the completion of a test. It will be seen that the automatic movement of the poise at a constant rate enables any number of tests to be carried out under uniform conditions, which is important in that the strength of some materials is considerably affected by the rate of loading.

Three sets of wedges are provided with this machine to take specimens of the dimensions stated above, and, if desired, a pair of clamp holders can be supplied to take thin strips up to 1 inch wide. In all cases the wedges are opened and closed by the movement of a single lever, which leaves one hand free to insert the specimens.

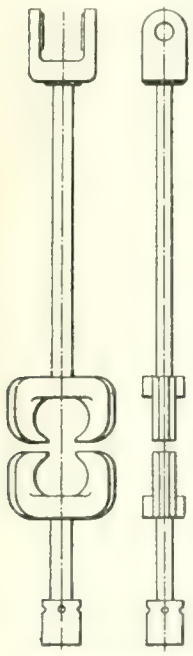

FIG. 5—CEMENT BRIQUETTE HOLDER.

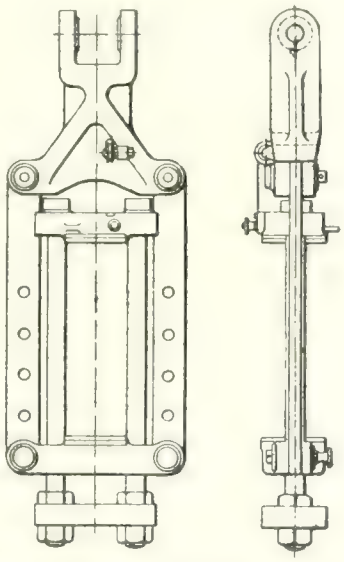

FIG. 6—COMPRESSION TOOLS.

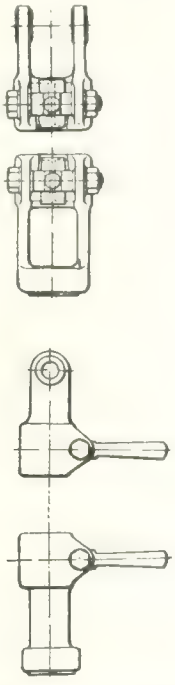

FIG. 7—TENSION TOOLS, TWO FORMS.

### 10,000-lb. Testing Machine

A machine adapted for similar work but lacking the automatic poise movement and of a wider scope is shown in Fig. 4. This machine has a capacity of 10,000 pounds and will take specimens up to 18 inches in length when stretched. It is of the single lever type and the steelyard is graduated up to 1,000 pounds, reading to 1 pound by means of a vernier attached to the poise. Additional loading, up to the full capacity of the machine, is obtained by means of loose weights, and, in favor of this system, it may be pointed out that tests requiring small loads, say up to 100 pounds, can be carried out with as great a degree of accuracy as those using the full capacity of the machine.

As mentioned before this machine is not provided with automatic means for moving the poise, so that the operator must use both the hand wheels shown when making a test, the lower one being used for straining the specimen and upper one for moving the poise. Accessories used for testing cement briquettes and for making bending and compression tests are shown in Figs. 4, 5 and 6, the apparatus used for bending tests being shown on the machine. Fig. 7, shows the usual forms of tension test clamps.

### Fabric Testing

Aeroplane manufacturers sometimes find it convenient or necessary to test the fabric used in wing construction, although such tests are generally made by the Government. This is the case when the effects of a new dope or wing varnish are to be known.

In testing fabrics the rate at which the load is applied seriously affects the results and to a secure uniform rate of loading the machine shown in Fig. 8 has been devised. The load is applied by allowing shot to fall from an upper fixed reservoir to a lower one suspended from the end of a lever to which the fabric is attached.

The flow of shot can be regulated so

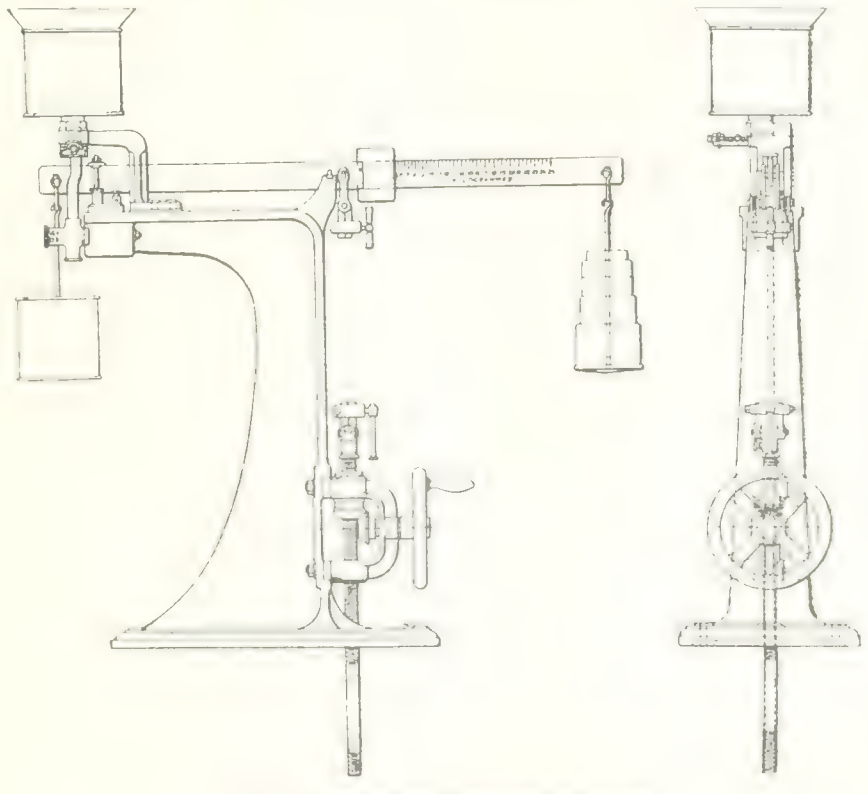

FIG. 8—MACHINE FOR TESTING FABRICS.

## POWER DEVELOPMENT NEAR MONTREAL

IN view of the present interest in the power development in Montreal and Quebec province and the apparent need of further development in the near future, the fact that Montreal Power can develop 300,000 horse power against the 240,000 which it will have by midsummer will be of interest.

The [illegible] Rapids is 100,000 horse power, though the water power development is 180,000 horse power. [illegible] horse power are now being installed, and will be completed by the end of July, when the power from the plant will be 120,000 horse power units, for the remaining 60,000 horse power will be installed as required.

Lachine and Soulanges plants develop from 12,000 to 15,000 horse power. The contract with Shawinigan would give the Power [illegible] 75,000 horse power.

The situation is that in a couple of months the company will have a nominal capacity of 240,000 horse power hydro-electric for distribution, and may increase this to 300,000 horse power hydro-electric simply by adding necessary units. In addition, its auxiliary steam plants have a capacity of 30,000 horse power available at any time.

This may be divided approximately, as follows:

| | H. P. |
|---|---|
| Power Co's. Chambly plant | 20,000 |
| Power Co.'s Lachine plant (12,000 to 15,000) | 12,000 |
| Power Co's. Soulanges plant (12,000 to 15,000) | 13,000 |
| Power Co's. Cedars Rapids by July 31 | 120,000 |
| Shaw W. & P. on contract | 75,000 |
| Hydro-electric power available by August | 240,000 |
| Cedars Rapids additional unit capacity | 60,000 |
| Hydro-Electric, totals | 300,000 |
| Capacity Co's. steam auxiliaries | 30,000 |

## EVERYONE MUST CONSERVE COAL

AT the close of the conference held here recently of coal operators, labor delegates and transportation representatives with Mr. Neale representing the United States Fuel Administration and C. A. Magrath, Dominion Fuel Controller, a memorandum was submitted by Mr. Magrath covering the chief developments of the conference, which lasted for a couple

The memorandum contained the important statement that the United States Fuel Controller felt it his duty to inform the Canadian Fuel Controller, so that he could pass the information to the Western Provinces of Canada, that the situation is as follows:

(1) That anthracite coal supplies to points in Western Canada will be very materially restricted during the present coal year.

(2) Under the circumstances it is safe to predict that no American anthracite coal will be available for shipment to points west of Winnipeg.

(3) It is also proposed to restrict shipments of anthracite to Canadian lake ports during the early part of the present season.

(4) That the public, both east and west, must be given to understand distinctly that conservation of coal must be practised to the utmost extent by all classes of consumers.

Mr. Magrath's memorandum said Sir George Foster had been able to announce that the attitude of the United States Fuel Administration was that Canada would receive precisely the same treatment as the various States of the Union. The Western States had been given to understand that they must use the softer coal of the West and that the available anthracite would have to be conserved for the purpose of supplying the eastern part of the Union and the Provinces of Ontario and Quebec.

## SHORTAGE OF MARINE ENGINEERS

There is a great shortage of marine oil engineers at the present time for commercial work. According to the *Motor Ship*, owing to the tremendous increase in the employment of internal combustion engines for war purposes of every conceivable class, the demand for men skilled in the usage and repair of this type of motor has been very considerable, and the result is that nearly every man in this position has been drawn from his normal work, even though he is over military age. Consequently the number of men remaining in civil employment who are qualified internal-combustion engine mechanics, or even reliable drivers of such motors, is comparatively small, and a good deal of difficulty has been experienced by owners of commercial motor craft to provide an efficient engine-room staff. This applies to all manner of vessels, whilst the motor ship is far from immune, many engineers having left motor ships to take up commissions in some branch of the Army, where a knowledge of internal-combustion engines is essential. Naturally, this fact is inimical to whatever prospects there might be of building commercial motor vessels at the present time, since owners realize the difficulty they will experience in obtaining suitable men to run such craft. The greatest difficulty is being experienced in connection with hot-bulb-engined boats, since there are extremely few men remaining out of the Army or Navy who have a satisfactory knowledge of such engines.

## RUST PREVENTATIVE

As a preventive from rust for machinery of all kinds, an application of iron phosphates has been found effective. The metal, after being thoroughly cleaned, is placed in a bath containing ferric and ferrous phosphates, a little manganese dioxide being added at boiling temperature. The articles should remain in the bath until hydrogen is no longer generated, then dried in the air, and painted, japanned or coated with mineral oil. The phosphate being attached chemically to the surface of the metal prevents rust forming at any spot. Marine motor parts, such as springs, or any portion exposed to the salt air, would be kept in good condition by this treatment.

## THE CAUSE OF WAVES

Waves in mid-ocean are caused entirely by the action of the wind. The adhesion between the rapidly-moving particles of air which compose the wind and the surface particles of the water causes the water's surface to be dragged along with the air. Small ripples are immediately formed, and these soon overtake others near them. They unite, and, due to the friction betwen the water particles, each succeeding ripple piles up on the top of the previous ones. Just as soon as oil is spread on the water, however, the size of the waves is reduced like magic. The reason for this is interesting. Oil, unlike water, has very little internal friction between its particles. The ripples of oil formed by the wind, therefore, cannot pile upon each other to any considerable height; hence water waves cannot grow in an area of oil placed about a steamer. They begin to fall down instead. By the time these waves reach the boat they will have lost their formative ripples.

## SALE OF AUSTRALIAN COPPER TO BRITISH GOVERNMENT

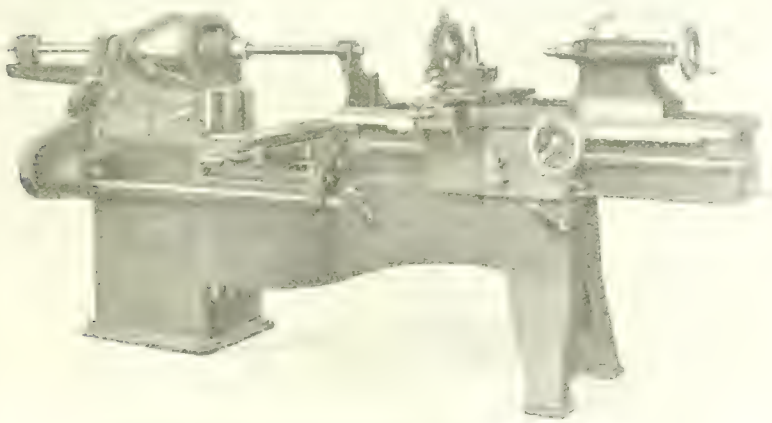
THE Australian Copper Producers' Association, recently formed by the principal copper mining companies, has accepted an offer from the British Ministry of Munitions, to June 30, 1918, for the Australian output of copper, excepting copper required for local consumption and copper sold under existing contracts. The amount of money involved under the contract will be approximately £2,150,000. The price to be paid for electrolytic and Wallaroo (South Australia) copper will be £108 per ton, and for other brands £106 per ton f.o.b. steamer at Australian ports. If the proportion of other brands exceeds one-fourth of the total tonnage the Munitions Department require an abatement in price of £4 per ton, thus reducing the price for the excess to £104 per ton. The maximum quantity which may be delivered under the contract is 20,000 tons, and the minimum 15,000 tons. If the maximum is exceeded the surplus will be taken by the British Ministry of Munitions at a price to begotiated. If, however, the minimum is not reached the Ministry of Munitions may claim delivery of the deficiency later at the contract price, but has no right to action for breach of contract.

# DEVELOPMENTS IN SHOP EQUIPMENT

*Notice of equipment and processes in metal working and machine shop practice, and illustrations of typical departments and machines.*

## COMBINATION LATHE BORING AND MILLING MACHINE

A MACHINE of a wide range of usefulness and of considerable adaptability is illustrated herewith. The construction permits of its use as a 16-in. engine lathe, a horizontal boring mill, a plain milling machine, or a sliding bed gap lathe.



MACHINE SET UP FOR USE AS A BORING MILL

Each unit is as complete and distinct as the same machines individually and gives the same range and capacity.

The base carrying the sliding member is strongly ribbed and the ways are scraped true to alignment for both carriage and tail stock.

The lathe carriage is made with the bridge on the end towards the headstock and extends out over the face of the apron to permit the use of the compound rest up to the full swing of 25 inches permissible in the gap.

The headstock is made with a four step cone pulley and is single back geared.

The milling machine table saddle and knees are of rigid construction scraped to accurate bearings on all moving surfaces. The table is elevated on the face of the column by means of helical gears and screw. The crank for operating the elevating gear is located on the face of the column in a convenient position for the operator. The standard machine is equipped with hand feed to milling machine table.

The horizontal boring mill is of the platen and table type. The boring bar is 1½ inches in diameter and is provided with power feed driven from the lathe change gears.

Power longitudinal feed to the milling machine table and additional equipment is furnished when desired.

The following dimensions of this machine are of interest: length over all with bed closed, 83½ ins., length with bed open, 105 ins., lathe takes between centers, closed, 36 ins., open 57½ ins. The lathe swings 17¼ ins. over ways and 32 ins. in gap, and will turn up to 25 ins. diameter. The milling machine has a longitudinal feed of 20 ins., a vertical feed of 20 in., and a cross feed of 7½ ins.

In the shop where a wide variety of work is handled the combination lathe-boring and milling machine is a valuable machine and enables the work to be accomplished with a minimum of investment.

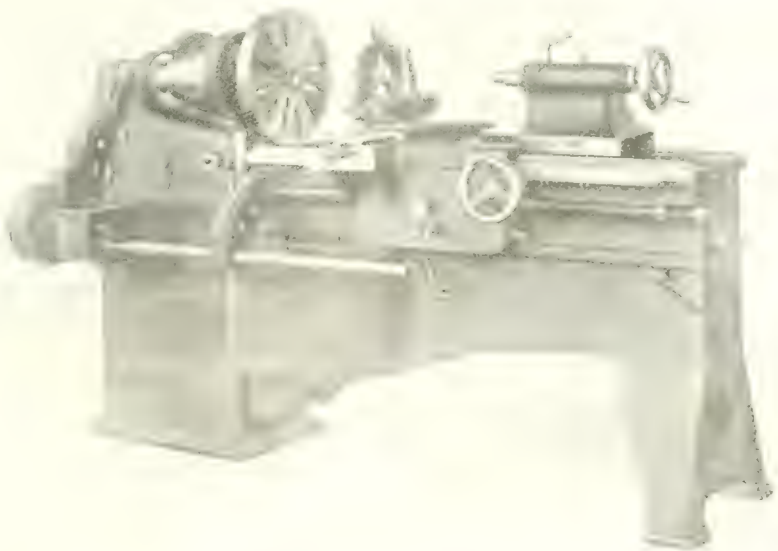
The G. W. Fleming Co., 16 Broadway, Springfield, Mass., are the manufacturers of this machine.

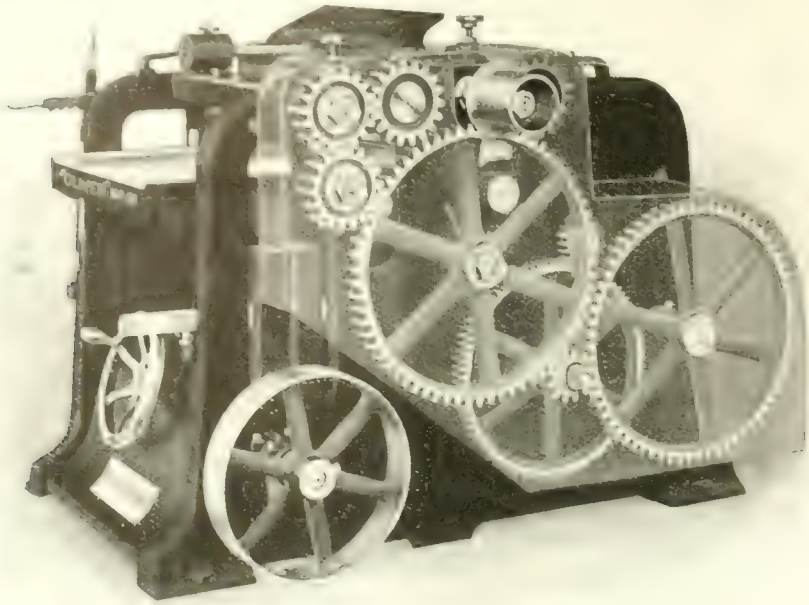
## CABINET SURFACER

A cabinet surfacer built by the Oliver Machinery Co. of Grand Rapids, Mich. is illustrated herewith. This machine has a number of improved features.

The demand for an accurate smooth planer capable of a wide range of work both in soft and hard woods is well met in the design of this planer, its correct design, compactness, feeding power and general efficiency making it readily adaptable to the requirements of pattern makers, aeroplane manufacturers, government shops, engineering works, shipbuilders and railroad car shops.

The machine is made in two widths





SINGLE CYLINDER FOUR ROLL DOUBLE BELTED CABINET SURAFACER.

tributed, eliminates strains and vibration.

To assure perfect balance, hence smooth planing, the cylinder is of the circular type, made of a crucible steel forging of uniform texture and belted at both ends. It carries two thin high speed air hardening steel knives securely clamped against hard steel chip breakers, whose lips are shaped to repel shavings and chips. The entire cylinder is nicely ground to perfect size. The journals are long, of unusually large diameter and machine ground.

The cylinder pulleys are two in number, and their faces are grooved spirally, preventing air pockets under the belts and augmenting the belt power through its close contact with the pulleys.

The cylinder bearings are of the self-oiling side-clamping type with large oil chambers. They are readily adjusted to hold the cylinder firmly in place for smooth planing. Readjustment of caps can be made instantly.

The back pressure bar follows the cylinder and is held by adjustable screws for regulating the hold-down pressure on the lumber as it leaves the cut. The throat between the front and rear pressure bars is only 2⅛ inches for service in planing smoothly and without end clipping on very short stock.

The chip breaking pressure bar before the cut holds the lumber firmly to the bed as it is planed, and prevents the chips from tearing its surface. It is attached to the main frame in such position that it raises concentrically with

raising into the knives. A steel spring shoe is secured to the lower part of the bar, which not only holds the stock firmly on the bed but yields to any ordinary inequalities in rough stock. An adjustable weight regulates the pressure.

The bed is of suitable dimensions, gibbed properly, and is raised in a wide central slide that is deep to give the bed the proper rigidity. A guide is located at each side to prevent material from leading away from the bed and striking the frame or gearing. The bed is supported on heavy square thread screws with ball bearings, reducing friction and permitting the raising of the bed without exertion. The bevel gears used in elevating the bed are machine cut and are protected from dirt by a wide shelf that covers the inner space below the table and keeps the shavings within the frame making it very easy to clean around the machine. Directly underneath the cylinder is a centre plate adjustable to wear, removable from the bed when worn. It may be redressed and refitted or discarded for a new one as the occasion demands.

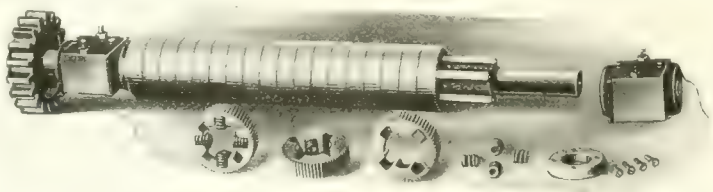
There are four feed rolls, one pair back of the cylinder to feed the material free of the knives and assist in carrying it through the machine. They are large in diameter, made of hammered steel and are supported in self-oiling boxes. The upper feed-in roll is corrugated for gripping the stock firmly. All the rolls are driven by a train of heavy gearing, three pitch, the teeth machine cut, insuring a smooth and positive feed. The feed-in rolls are weighted and the delivery rolls have spring tension. The upper delivery roll has a cover over it and is provided with a scraper which keeps the rolls free from shavings.

Sectional feed rolls may be provided when so desired. It consists of sections 1⅛ inches wide and 4 inches diameter. While giving a horizontal drive as positive as a solid roll, they yield vertically independently of each other to the extent of 3/16 inch. Each section is composed of an outer ring enclosing four sections or seats placed radially to the centre of the roll shaft and each carrying a helical spring.

The sectional chip breaker consists of 1⅛ inch sections pivoted in connection with section weights, on two horizontal bars attached to two plates. They yield concentric to the cylinder independently of each other.

The gearing that transmits the power to the rolls is all machine cut and perfectly finished throughout. Such gears as revolve on steel studs are provided with oiling devices that are right. Grease cups mounted on each stud furnish oil through channels in the studs to the inner surface of the hubs, producing effective lubrication. The studs are large and the bearings for shafts that pass through the machine are fitted with dust-proof spring oilers. The master driving pinion is hammered crucible steel and machine cut.

A grinding attachment is provided which will quickly and accurately grind the knives of planers and jointers without the trouble of taking the knives off the machine. The attachment can be quickly mounted on the machine or removed therefrom. The motor is mounted in grinder head; current is taken from an ordinary lamp socket.



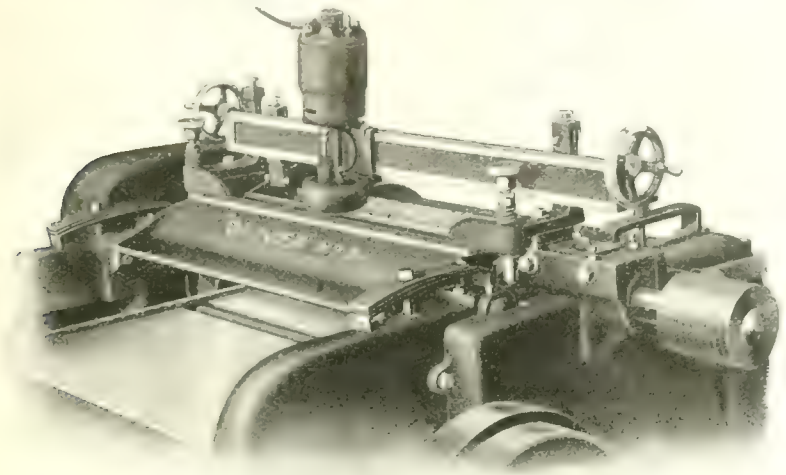
SECTIONAL FEED ROLL SHOWING POSITIVE DRIVE AND STRONG CONSTRUCTION.

## AUTOMATIC ELEVATOR FOR SHELLS

THE AUTOMATIC elevator illustrated in the accompanying engraving has been recently designed and erected by Ed. Bennis & Co., Ltd., of Little Hulton, near Bolton. It is arranged both to elevate shells or similar cylindrical bodies from a lower to a higher level, and to lower them, and can perform these operations simultaneously. A feature of the appliance lies in the fact that the articles do not pass round the top or bottom drums either when being raised or low-

ered, the feeding and discharging in each case taking place on the same side of the elevator.

The elevator can conveniently be bolted to a wooden framework. This framework is provided with bearings for the shafts of the top and bottom drums



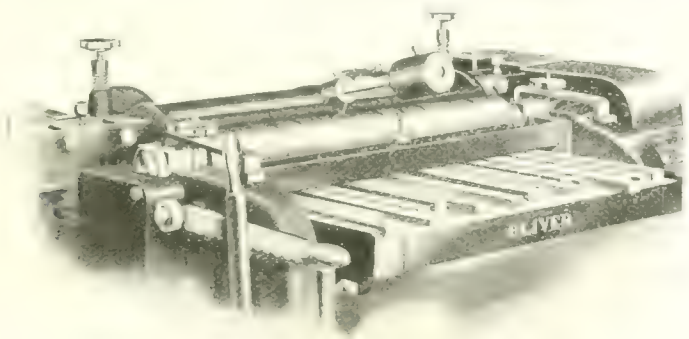
GRINDING JOINTING AND SETTING ATTACHMENT IN USE.

shown in the engraving. These drums are of cast iron, and are provided with sprocket teeth to engage the elevator chains. The shaft of the upper drum is extended to carry a driving belt pulley. The endless elevator chains are two in number, and are formed of cast steel links united by mild steel rivets. At intervals the two chains are connected crosswise by a horizontal rod. These rods serve as spindles whereon the shell carriers are pivoted. The carriers are built up of lever-like cast steel bossed plates A, the number of such plates in each carrier varying with the length of the article to be lifted.

The plates, pivoted on the cross spindle at B, are riveted together at C, and are joined by an axle at D. This axle does not rotate, but carries at each end

turned steel prongs J are fixed. The plates of the carrier passing between these prongs lift the lowest shell, which rolls into the position shown at K. On reaching the level at which the shells are to be discharged, the rollers of the carrier pass into a bend L in the guides F. This causes the carrier to tip the shell on to the gently-sloping discharging table M, the end of which is provided with straight prongs.

Passing over the top sprocket drum the carrier, now upside down, is available for lowering shells from the level N to the level P. The table at N slopes gently towards the elevator, and at its end is provided with a group of pivoted and balanced prongs Q. Two of these prongs are formed with projecting lips R against which projections S on two of the plates of the carrier strike during the descent. The shell resting on the prongs Q is thus allowed to fall into the hollow on the back of the carrier, as at T, is lowered thereon until it reaches the fixed straight prongs U on the end of the lower table P.



VIEW OF AXLE SHOWING FEED ROLLS

a roller E, the body of which is hollow and filled with lubricant. The rollers work against two pairs of mild steel angle iron guides, F, G, fixed to the wooden framework.

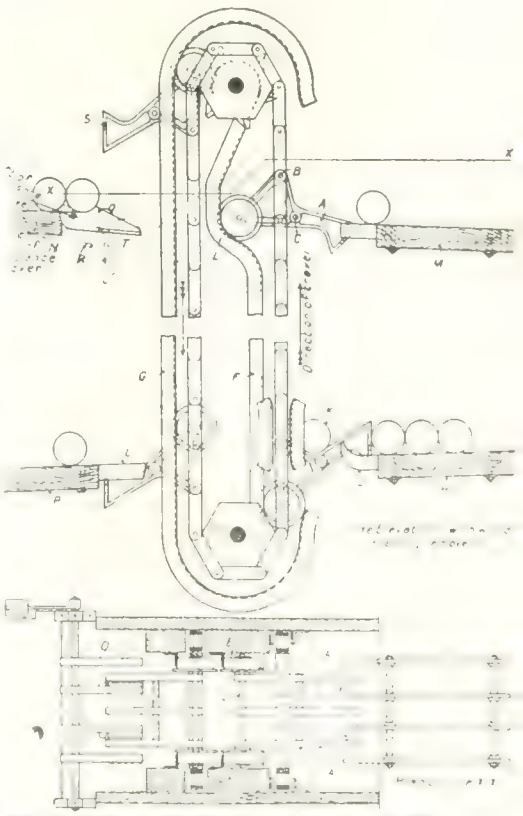
The shells to be raised approach the elevator by rolling down a gently sloping table H, at the end of which up-

## NO PASSPORTS WITHOUT CREDENTIALS

ALL American seamen must now show a seamen's certificate of citizenship, or intention to become such, before they can obtain their passports to sail coastwise or overseas. This applies to licensed officers as well as seamen, engineers, firemen, coal passers and stewards. Aliens must have a certificate of nationality issued by their respective consuls or be able to show continuous discharge books from previous employers. No alien enemies will be allowed to ship on American vessels of any sort, or on the vessels of the British Allies. It is very important that this information should be impressed on sailors, as they have not yet realized that they absolutely must show their papers as described above to obtain passports.

## THE WORLD'S PRESENT MOST VALUABLE ASSET

IT is predicted that the demand for tonnage will be even greater in 1918 than it was in 1917, and the utility of ships will enormously increase. The economic world crisis, however, it is believed, will not reach its climax until after the war. If



PLAN AND ELEVATION OF SHELL ELEVATOR

the law of supply and demand was allowed to operate, ships might some day be worth their weight in gold to their owners, but in the present controlled state of trade their immense value as national assets really detracts from their value as money-making instruments. Ships are, and will continue for some time to be, the most important factor of all in helping to preserve the lives of nations, and the States of Europe will not be likely to slacken their ship production and acquisition after the war until there are sufficient craft to ensure safety in regard to supplies of food and other essentials. The nation, in fact, that owns the greatest amount of tonnage and has it under the best control will have the most valuable asset when the war closes.

## CANADIAN PROJECT MEETS WITH WIDE APPROVAL

A [illegible] Washington [illegible], the commendatory opinions which have been expressed throughout the Dominion regarding the projected plate mill plant in Nova Scotia. Such a step will afford considerable relief to the mills in the States with ultimate beneficial effect on congestion generally.

Announcement has also been made that the first order for steel has been placed in the States for the Canadian shipping program, calling for 80,000 tons of plate and sections. With the gradual increase of government ship work, as the Munitions Board vessels are completed, the volume of material required will assume considerable proportions, and in this respect much interest attaches to a recent statement by the management of the immense Hog Island yard that an average of two months elapses from the time the steel leaves the mill until it reaches the shipyard in fabricated form.

The additional four months required from the time the keel is laid until fitting out is completed mean that six months is required from the time the steel leaves the mill till it is afloat ready for duty.

An idea of the prospective load on transportation facilities in the States may be gathered from the fact that thirty-five shops, widely distributed, are engaged on the work of fabrication: this for one yard's output alone.

The Canadian program we understand calls for the adoption of the fabricated steel system of ship construction and if the plans adopted correspond to those now in use in the States, a high degree of output may be rapidly attained in the Dominion yards.

While the completion of the plate mill is quite some time distant, possibly eighteen months, some advantage may be gained by the fact that two-thirds of this time will be normal weather conditions allowing maximum rate of preparation. It is also not unlikely that in view of its desirable effect on traffic conditions south, the work of building the new equipment will be afforded every facility by United States authorities for rapid completion by the builders.

The project marks an epoch in Canadian industry, and its advent at the present juncture justifies the importance with which it is regarded in the eyes of the industrial leaders of the United States.

## THE NEEDS OF CANADA IN REGARD TO INDUSTRIAL RESEARCH

THAT scientific industrial research has proven its worth in cold cash as a business investment was stated by Professor F. C. Fields of Toronto, in a recent public address, although the initial cost of such expenditure is one of the chief obstacles to a more liberal attitude towards research on the part of many manufacturers.

Figures given by Professor Fields regarding such work in America are illuminative:

"In the case of one firm, an investment of $25,000 in two years had yielded assets of $200,000 and an annual profit of $1,000,000. In another case the same investment in 18 months was bringing a profit of $50,000.

"In one instance an investment of $25,000 in four months paid $1,500 per day."

Such instances of course are confined by the nature of circumstances to a limited number of firms, and in the broad national aspect are not of benefit to the population as a whole except via the sales department of the firm making the investment. All that is right and proper, but such a feature differs essentially from British practice which has been considerably accelerated of late.

The "State Department of Scientific and Industrial Research" in Great Britain has a fund of a million pounds sterling at its disposal and among its activities it has been founding co-operative laboratories for manufacturers in similar industries, the department defraying the costs.

The Council of Industrial and Scientific Research in Canada has ample precedent for its existence and while numerically its results may be less than those of similar bodies of other countries, it is a national necessity and as such should be kept closely in touch with by manufacturers throughout the Dominion.

Only by knowing what to look for can the efforts of such an institution be efficiently directed, and while natural resources offer many fields of application, the industrial life of the Dominion will become more consolidated if manufacturers once see the possible benefits to be derived by judicious consultation with the council.

## INTERNATIONAL INFLUENCE OF U.S. MACHINERY DEALERS' CONVENTION

CANADIAN machinery manufacturers and dealers are taking more than passing interest in the thirteenth annual convention of American associations connected with this branch of industry.

Just as the United States did not at first fully realize the magnitude of Canada's war effort, so are we liable to be misled by incorrect, exaggerated, and otherwise erroneous reports regarding our ally's activities.

Much information of a military nature will not be available, but much information, of a kind designed to assist individuals and firms in the efficient discharge of their duties as loyal citizens of a country at war, will be made available by the three supply and machinery associations concerned.

The event is particularly interesting in many ways. Secretary of War Baker; Charles A. Hinch, president of the American Bankers' Association; Fairfax Harrison, president of the Southern Railway, are expected to deliver addresses.

The impressive aspect of the convention is that machinery dealers and manufacturers are receiving the approval and personal co-operation of government, banking and allied interests in their efforts to serve their country.

It is now thirteen months since the United States declared war on Germany. Much of that time has been too strenuously occupied with active preparation. Although the first rush is still on and will be on till the end, the organizing instinct, the team-work microbe, has now got to the surface and the racial characteristic for co-operative discussion will be given full play.

Canada missed much of this propaganda work when it was most necessary, but just as peace time knowledge has been utilized in war, so can war time activities and ideas be studied with a view to peace however distant. Personal addresses by prominent officials of the leading industries concerned will be of a nature calculated to exert a powerful and beneficial result on the efforts of those concerned.

The closely allied and parallel paths of Canada and her big neighbor make the event truly international in the machinery world.

# Has Not a Moulding Apprentice in the Shop Although Wages Are Running High at Present

## Workers Have Given Good Satisfaction in Some of the Shops Where They Have Been Employed.

[illegible] there does not seem to be a well-organized apprentice system in the trade would seem to threaten a serious situation [illegible] more seriously affected than the manufacturer of stoves.

"We have not an apprentice in our shop to-day," said Mr. Charles Stewart of the Stewart Mfg. Co., Woodstock. "It cannot be said that there is no money in it for young men. We have offered unusual wages to beginners but they seem to prefer other work at less money. The men we have with us to-day have been with us for years, and same of them are [illegible] good workmen, and under the circumstances are worth the money, but they will not work six days a week. It may be that they are better men for the extra day's recuperation, for they certainly go some while they are at it.

"But the question is, how are we going to fill the ranks as they are thinned out? I understand that there are 200 moulders in Toronto to-day who are working at other trades. Are these men going back to the bench when there is no longer work for them elsewhere? Not likely if they can get as good money and cleaner work. What, then, is the remedy? Another stove manufacturer told me the other day that he had a shop full of apprentices but that they were all foreigners, and therein seems to be the only solution of the problem. Foundries must have moulders and I suppose it is hardly fair to expect the government to require that all tradesmen should seek employment in their own particular trades. That would be encroaching on personal liberty. Let us hope that this is one of the many problems to be solved after the war."

Mr. Stewart observes that scarcity of material and labor and consequent high prices would seem to induce falling off in demand, but it is a present-day peculiarity that the opposite is the case.

### About Women Workers

[illegible] tool makers, Galt, have been employing several young women in their factory for some time, and Mr. Preston states that he is more than satisfied with their work.

"It has not always been possible to secure men," he said, "and our experience is that on certain classes of machine work, such as repetition processes, we could not have done better than employ girls. Fortunately there has been available a certain amount of help that has had fine machine experience. For example, [illegible] have worked on shoe or knitting machinery have a practical aptitude and are quick to learn the different lathe manipulations. I do not say that we have placed them on calculative work or fine adjustments, but when they understand [illegible] operations that are necessary the work as a rule is done quickly and with intelligence. Ours of course is a light class of work, such as a girl could engage in at any time. After the war many of the girls who are employed in such plants as ours may seek other employment, but not because they have not made good on certain classes of work in the machine shop.

# HUDSON BAY MINERAL WEALTH IS LARGELY IN HANDS OF AMERICANS

APPARENTLY the people of the [illegible] the mineral wealth of the Hudson Bay district, especially in copper and gold, large quantities of which are already taken annually from the rocky sections of that country. CANADIAN MACHINERY had an interesting talk with A. D. Porter, who has been on the engineering staff in charge of the construction of the Hudson Bay Railroad, which is now held up on account of the shortage of steel, and the fear that some of the work may have to be lifted to make up for the shortage caused by taking Canadian steel to Europe.

Le Pas has been Mr. Porter's headquarters for some time past. The road is now built for a stretch of 380 miles, to Kettle Rapids. "It has not been a bad country to build through, one of the chief troubles being muskegs. Big bridges have been constructed, principally at the Saskatchewan river, Manitou Rapids and Kettle Rapids. The latter was a particularly hard piece of work. The water is deep and rapid and much of the work was carried on in the very cold weather, and by cold I mean 40 below for days and weeks at a time. Ninety-pound steel has been used so far on the road, but there is a chance that this may be brought to a lighter type if the work is carried on at all.

In answer to a query about the minerals of the country, Mr. Porter said, "The country is rich beyond words, in copper and gold, and what else I don't know. The Mandy Mining Co. took 9,000 tons of copper ore from their property. They team it on an ice road to Sturgeon Landing on the Saskatchewan, then it comes down to Le Pas. From there it is loaded and shipped away off to Trail, B.C., for the purposes of refining, and even with all that handling they make a good profit out of it. To give you an idea of the mineral wealth of the quartz, a team of mules took nine tons in one load from the mine along the ice road that they use. But it's all American capital that is interested in the property. Then there is gold at Herb Lake, some ten miles from the railroad. The provincial government built a wagon road in there, and the quartz that is taken out is rich stuff. McKeefer Bros., of Boston, have a stamping mill there, and when the ore is broken up the free gold can be seen very plainly, and in liberal quantities.

### Other Natural Resources

"Then there is the spruce timber being cut there," continued Mr. Porter, "I don't believe there could be finer wood. Fishing is carried on very extensively by the traders and Indians, and furs are sold largely to the trading companies and New York buyers."

Mr. Porter's brother, J. W. Porter, is chief engineer on the work of the Hudson Bay road. The mail comes to their headquarters every two days, and in that way they get a fairly good news service. "I have read CANADIAN MACHINERY for the last ten years," said Mr. Porter, "and through that paper I have been able to keep in touch with what is happening in engineering and machinery lines while I have been more or less out of touch with them in Northern Manitoba." Prior to working on the Hudson Bay road Mr. Porter was engaged in railway work in Montreal and other points, and filled a number of responsible positions, also having much to do with the outfitting of the C.N.R. For the past month he has been in Toronto working on the valuation of the C.N.R. rolling stock in connection [illegible] the worth of the stock.

# MARKET DEVELOPMENTS

# War Demand for Steel Dominates Situation

## More Steel Required for War Work—No Permits on Steel Plate for Stock—Machine Tool Market More Active—Tin Continues Very Scarce and Again Advances—Shortage of Steel Scrap.

SIGNS are not wanting that the orders for shells from the United States will be an important factor in the munitions industry in Canada this year. Already considerable contracts have been placed and indications point to interesting developments in this connection. Not only will the adverse balance be reduced materially but the additional flow of money into Canada will benefit the manufacturers and the country generally. Already there has been quite a revival in the machine tool trade on this account, and a stimulation among Canadian makers to build new and special tools for this purpose. This is an important development and one that will have a beneficial effect on the trade. The need for steel for war purposes is indicated in a new arrangement backed by the War Industries Board whereby steel is to be distributed in a classified order of priority. By this means firms engaged on war orders will have first claim on the mills, and when their requirements have been satisfied the balance will be allocated to the ordinary consumer. An order has been issued from Ottawa stating that no more export licenses will be issued by the United States Government until further notice on shipments of steel plate to Canada when required for stock. This again makes the position of the private consumer increasingly difficult. The demand for steel products in Canada continues good but merchants are handicapped by the difficulty that is being experienced in obtaining material. The scrap metal market is quiet and business continues dull. Buyers are keeping out of the market as they anticipate lower prices. There is a serious shortage of heavy melting steel and cast iron scrap with the result that prices of these materials are holding very firm. There is a good demand for machine shop supplies stimulated by the activity in the munitions industry. Prices are generally firm with an upward tendency in some lines. The continued scarcity of tin is the outstanding feature in the non-ferrous metal markets. This metal is in very short supply and there is no sign of relief in sight. The price of tin has advanced. It is asserted in some quarters that the fixed price of copper may be advanced to cover increased producing costs. Lead and spelter are easier and prices are lower. Solders have advanced on account of the acute tin situation.

## INCREASED ACTIVITY IN MUNITIONS INDUSTRY

### Opening of Navigation Will Relieve Freight Situation

MONTREAL, Que., April 29, 1918.—The feature of industrial activity in Montreal and the surrounding district is the revival of the munitions business. The decline that was apparent in this direction some six months ago or more has again given place to increasing business, more particularly in the demands for shells from the American Government. Large orders have recently been placed with a Montreal firm for the production of the 9.2-inch shell. This contract, while coming from the United States, will be identical in character as former shells of this particular size, as the ordnance of the American army is being adapted to conform as close as possible with that of the other Allies to avoid complications. One firm here has recently obtained an order for 155 m.m. shells for the American Government, and equipment is being obtained as rapidly as possible. In connection with one of the largest contracts ever placed by the American Government for valves for navy requirements an engineering firm of Montreal succeeded in obtaining business to the amount of over $65,000. This firm's total business for the year that has passed did not reach the total of this one order, and the manager recently intimated that his prospects for the present year would be close to 2½ millions. A feature of present developments is the suppressed interest that is being displayed in the demand for fuel conservation. Several local firms are planning to instal electric units in place of the steam equipment now in use, buying outside power from companies that are now generating current from water sources.

#### Steel

Steel activity throughout the district continues quite brisk, and consumers who are dependent upon shipments from outlying points report that they are getting better delivery than they have had for many months. This is partly due to the relief that has come with the opening of navigation and the consequent greater supply of cars that have resulted; in addition the various roads are gradually obtaining more cars for freight transportation. Local steel plants, both those that are working on rolled steel for light and heavy bars and those engaged in making billets for different-sized shells, are very active. Some little difficulty is still experienced by those plants working on the 75 m.m. shells in getting an ample supply of forgings for capacity operations. In this connection, however, Canadian manufacturers are endeavoring to overcome the handicap, and one firm in this district is now producing sufficient forgings for maximum operations on the machining of the shells. The delivery of plates to the steel shipbuilders is more encouraging, although there are times when operations are slightly suspended owing to the lack of sufficient material. One of the engineers of a plant in this district said "that it did not take very long to consume a thousand tons of steel plates, and there are times when we are necessarily waiting for a further supply." With the summer approaching, this firm anticipates better delivery of plates and expect much better progress in the construction of the vessels. Canadian mills making small-sized plates are reported to be exceptionally active, as this class of material is becoming more difficult to obtain from steel mills in the States. The local dealers report conditions that are practically normal in comparison to the activity of the past several weeks, but intimate that delivery has shown much improvement. The difficulty of placing orders with any assurance of definite delivery is still pro-

nounced and will likely continue so under the present pressure of business. Practically all quotations are held at last week's figures.

### Metals

With the exception of tin the metal market is normal in character and the general demand steady, with little to feature the developments of the week. Copper continues to be firm, but interest is centring in the possibilities of an advance in price. Tin continues to hold the place of honor in the metal movement and the situation here is nervous and acute. Spelter is very quiet, as lack of even moderate buying has given the metal an additional weakening tendency. Lead continues firm, although the demand has not been very heavy. Antimony and aluminum are unchanged, but relatively firm in prices asked.

**Copper.**—Little development has taken place to alter the firm tone of the market, and buying here has been very steady. Some interest is being shown locally over the prospect of the American Government, acceding to the demand of the producers for a higher price for this metal. Just what attitude the Government will adopt in this particular is not clear, but some sections of the trade apparently believe that a slight advance may be made. Dealers here continue to ask 29c and 30c on a steady market.

**Tin.**—The extreme scarcity at the present time has resulted in an exceptionally strong market, both here and in New York. This additional strength has developed from the announcement that a recent shipment of tin from England has been sunk in transit. This has created a temporary shortage on this side and quotations have jumped upward. Local dealers are asking as high as $1.10 per lb., this being an advance over last week of 10c per lb. The demand, however, is not very heavy at present, as many of the consumers are conserving as much as they can the supplies they have on hand, these supplies having been obtained before the situation became so acute. Dealers here are looking forward to an easier market within a week or so.

**Antimony.**—This market has developed a weaker tone owing to the decline in the demand and the plentiful supply of metal. The local situation is reflected in the easier quotation, dealers here asking 15c per lb., a decline over last week of 2c per lb.

Spelter, lead and aluminum are unchanged, both as regards the demand and the dealers' quotations.

### Machine Tools and Supplies

Activity throughout the machine tool trade is apparently steady, although not over active; inquiries are still coming in for medium-sized machines suitable for 4.7-in. and 6-inch shells. One large firm here is getting plans out for certain machines and intend to construct them in their own plant. The designer of these machines has installed many of the smaller sizes in different shell plants, but has had great difficulty in getting firms to undertake the manufacture of them, one of the reasons being that the firms complain of being unable to get sufficient skilled labor to produce the work.

## POINTS IN WEEK'S MARKETING NOTES

**Canadian firms are making special machine tools for munitions plants.**

**Machine tool trade more active as a result of American shell orders.**

**Export licenses for steel plate for stock will not be issued by United States Government until further notice.**

**Stocks of plate in Canada to be conserved and only used for more urgent requirements.**

**Munitions contracts placed in Canada by United States Government may total $100,000,000. Orders already placed include 12-inch, 9-inch, 155 m.m. and 75 m.m. shells.**

**Reported that Allied war orders will be transferred from the United States to Canada to speed up deliveries.**

**War Industries Board will distribute steel in order of priority according to urgency of requirements.**

**United States Government steel requirements growing heavier, absorbing a large percentage of output.**

**Sharp advance in tin, due to serious shortage, with no relief in sight.**

**Lead and spelter both easier, and prices have declined.**

**Copper prices come up for consideration shortly. Report states that prices may be advanced.**

Some dealers here report that goods are being received more promptly, but shipments from the States are still uncertain owing to the delay resulting from the necessity to obtain import license. Demand for small supplies of every description is very active, and prices in most cases are well maintained.

### Scrap

Little change is noted in the activity in old materials, as dealers here report a situation that is not encouraging owing to the uncertainty that apparently pervades the market. Consumers are only interested in immediate requirements, and heavy buying is not pronounced. Steel turnings for electric steel making are in fair demand, and prices are very firm. Brass and copper scraps are steady, but with a slight undertone of weakness. The general tone of the situation is one of firmness, but dealers would like to see a release of the tension that seems to dominate the market.

## BETTER DEMAND FOR MACHINE TOOLS

### Manufacturers Building Special Tools for Munition Plants

TORONTO, Ont., April 30.—In order to take care of the adverse balance of the trade against Canada with the United States, it is likely that large contracts for munitions and other lines of war orders will be placed in Canada by the U.S. Government. It is understood that munitions orders alone to the extent of $100,000,000 will be placed in Canada, while possibly several millions of allied war orders placed in the States will probably be transferred to Canada. This will also have the effect of relieving the congestion in some lines of war orders in the States where deliveries are said to be months behindhand. The expenditure of such large sums of money will be a great benefit to this country and also correct the adverse balance of trade against Canada. Already large orders for shells have been placed, and others will likely follow in due course.

### Steel

All indications point to more complex conditions in the iron and steel trade in the future than at any period previous to the present time. The insistent demand for steel for war purposes has created a most difficult situation for the ordinary consumer, and it is unlikely that conditions will improve until the war is over. An instance of the difficulties that consumers and dealers have to contend with may be shown in an order or regulation recently issued from Ottawa. The War Trade Board has informed dealers that no more export licenses will be issued by the U. S. Government until further notice on shipments of steel plate when required for stock. Dealers have also been instructed to conserve supplies on hand, and it is also intimated that no material will be released from stock without a permit from the War Trade Board at Ottawa for each individual shipment. Supplies of plates and sections for shipbuilders are arranged for direct between Ottawa and Washington so the order will not affect war activities. Merchants, however, will be hit and the private consumer also. They have no redress as the urgency of war demands is solely responsible.

A recent development in the United States indicates that the position of the ordinary consumer is becoming increasingly difficult. What happens over there will in a measure be reflected in Canada. Every day it is becoming more apparent that the commercial market for steel is growing narrower, because such a large percentage of the output is being absorbed by the U. S. Government, leaving a comparatively small tonnage available for private use. According to a new arrangement steel is to be distributed in a classified order of priority in which the national needs are so prominent and so heavy that anything else will receive

little attention. From this it follows that permits will in future be more difficult to obtain and the civilian consumer will be the first to suffer. Canadian car builders will require about 80,000 tons of steel bars, plates and shapes for the construction of cars and 30,000 tons of cast, rolled and forged steel for building locomotives, orders for which have been placed the last few weeks. This steel tonnage is probably a part of the 700,000 tons reported on order with American mills for shipment to Canada.

### Pig Iron

In regard to supply there is very little improvement to note in the domestic pig iron situation. Oil the maleable and foundry pig iron that is being produced quickly passes into consumption. The demand for basic iron continues insistent and is beyond the capacity of the furnaces. In the States very little pig iron is being sold except through government intervention for consumers that are working on war contracts, but there are few foundry interests that are not working either directly or indirectly on war orders. It seems probable that the iron industry must come more than ever under government control, in which case the furnaces would be relieved of the responsibility of satisfying the demands of their customers. Receipts of coke at the furnaces have increased, but deliveries have been irregular and furnace operations have not increased to the extent anticipated.

Steel manufacturers and importers of ferro-alloys are concerned over the embargo on ferromanganese, effective May 13. The trade is especially desirous of knowing if the embargo applies to manganese brought on British ships as well as on those operated under the American flag. The impression is that it would restrict importations of ferro-manganese carried by any vessel into United States ports. It is hoped that mining of manganese ore in the United States may be stimulated by the war necessities of the steel manufacturers. The price for 70 per cent. manganese remains $250 per ton, but the market would readily rise under present conditions were it not for the probability of government price-fixing. It is possible that ferro-manganese could be shipped from England into Canada, and thence overland into the United States, but British supplies are short and Canadian manufacturers are trying to obtain ferro-manganese here.

### Scrap

The market for old materials continues in much the same condition as has obtained for several weeks. There is a marked disinclination on the part of buyers to operate, while on the other hand dealers do not appear to be particularly anxious to sell. Business consequently is decidedly dull and shows little or no indication of activity in the near future. Heavy melting steel and cast iron scrap are still very scarce at firm prices, with so many electric furnaces now operating in Canada there is not much chance of stocks of steel scrap accumulating as supplies soon pass into consumption. In this connection a market has been found for shell borings and turnings. There are no price changes to report this week.

## U.S. NAVY VALVE REQUIREMENTS LARGE

**Canadian Firm Secures a Contract for Reducing Valves**

SOME idea of the magnitude of the shipbuilding activity may be gathered from the data herewith in connection with the recent bid for valves for use of the United States Navy Department. This bid is known as Schedule 1712, steam engineering section, and was opened on April 2. The aggregate number of valves required on this particular schedule is about 834,000, this quantity comprising all types of valves. The class of valve of which the greatest number is required is the ordinary globe valve, the requirements being upwards of 383,000, about 143,000 of these going to the yard at Norfolk, Va. The total number of ½ inch globe valves will be approximately 75,000. The total number of gate valves of various descriptions will be in the neighborhood of 70,000, these include steam and water valves and 100 or more 1½ inch quick opening for low pressure. The bid calls for nearly 2,000 pressure relief valves, including snifting, muffler and air types; 880 are of the flanged variety, ranging from 1 inch to 1½ inch in size. The total requirements for check valves including swing, horizontal and vertical, and will approximate 132,000. Pressure reducing valves will number about 4,000; these will be for reduction from 175 to 25 lbs. per sq. in., exclusive of about 600 of a heavier type requiring a pressure reduction of 300 lbs. per sq. in. to 30 lbs. per sq. in. Radiator valves of various sizes will be required to the number of about 9,000; these include lock shield, renewable disk, and plain globe and angle types. Many of these radiator valves will be nickel-plated; about 1,000 of the ⅛ inch size being automatic. Nearly 1,100 ⅛ inch needle valves will also be required. When it is understood that the above requirements are exclusively for American navy purposes, the activities in the marine field are very remarkable. In connection with the above it might be stated that a certain Canadian engineering firm have received a contract for the manufacture of about 2,500 of the small size reducing valves, the amount of the business being well over $50,000.

### Machine Tools

A marked revival in the machine tool trade has followed the placing of American contracts for shell in Canada. The sizes covered in the contracts include 12 inch, 9 inch, 153 m.m. and 75 m.m. In the millimetre sizes some new and special equipment will be required for certain operations, for the 12 inch heavy tools will be required. An interesting development of this new business is the impetus which will be given to the machine tool industry in Canada. Neither the Canadian or U.S. Governments are encouraging the importation of machinery, with the result that Canadian makers are becoming more interested in this market and a number of firms have taken up the manufacture of new lines.

### Supplies

The market for machine shop and mill supplies continues active and seems destined to remain in this condition for some time. The revival in the shell business and fitting up of new plants will stimulate the demand for supplies generally. Express shipments lately have not been coming forward as regularly as formerly. Dealers complain of packages going astray and shipments as a rule being delayed in transit. The heavy burden on the express companies has doubtless something to do with this state of affairs. There are no price changes of importance to note although there may be an advance in lubricating oils in the near future.

### Metals

In the non-ferrous metal markets, tin continues to be the principal object of interest. Prices have again advanced and the metal is still very scarce with no indication of increased supply. Copper continues unchanged although it is reported that the War Industries Board may advance the price to 24¼c at the conference which is to be held shortly. Lead and spelter are both easier and have declined. Solders have advanced. Business continues very good locally and the outlook favorable.

**Copper.**—The principal feature of importance is the conference which will be held shortly by the copper producers and the War Industries Board. It is reported that the fixed price of copper may be advanced to 24¼c as it has been estimated that there has been an advance in producing cost of ¾c since the date when the present price, 23½c was agreed on. The market is quiet and quotations are unchanged. Lake and electrolytic are quoted at 28½c and casting at 28c per pound.

**Tin.**—This metal continues in the same unfortunate position. There is no spot metal offering. Small lots have been reported sold in the last few days in New York at as high as 95c. It is not a question of price now but one of obtaining the metal. Inquiries for tin of any grade and in all positions indicate anxiety of consumers to obtain a supply but the holders of Chinese, which is the only tin which can be offered with any assurance of delivery, ask so much for their products that buyers hold off as far as possible. Straits and Banca tin are for the time being out of the market. Tin has advanced again and is now quoted at $1.05 per pound.

**Spelter.**—The market is easier and prices have declined ½c per lb. Little interest is being shown in spelter and business is consequently dull. It is understood that the British Government

# SELECTED MARKET QUOTATIONS

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning—with rigid single bar for boring, or with swivelling bar for inside profiling.

### Plate Rolling Mill Plans

Special to CANADIAN MACHINERY.

WASHINGTON, April 30.—Closest co-operation between the United States and Canada is being planned here in the carrying out of the shipping programs which have been adopted by both countries.

Announcement made here during this week of the ambitious program adopted in Canada under the direction of C. C. Ballantyne, Minister of Marine and Fisheries, has aroused interest and the various administrative bureaus of the United States are now making plans to fit the shipbuilding plans of the two countries together. Announcement that plans are being made for a great steel rolling mill in Canada have been very gratifying to the War Industries Board because such a step will afford considerable relief to the mills in the United States and will relieve the congestion to a considerable degree. The outline of the plans for the Canadian mill have not been made complete here yet but officials are in hopes that a co-operative agreement can be reached between the two governments ... will effect a far greater steel out... for shipbuilding than is now available, without restricting the use of steel for other purposes.

Until Canada can establish the proposed steel rolling mill the United States will furnish that government with the supplies of plates and angles necessary for their shipbuilding program. This has been made possible ... W. Purchases ...nission, the War Industries ... and other government bodies working in co-operation with members of the Canadian War Mission.

It has been announced here that the first order for steel for the Canadian shipping program has been placed in this country and it calls for the delivery of 50,000 tons of steel plate and angles. The agreement made for the purchase of this supply of steel calls for prices for the Canadian Government which correspond to the prices paid by the United States Government. In the meantime the eyes of the industrial leaders of the United States are turned to the efforts of the Dominion Iron and Steel Corporation in its efforts to produce a Canadian steel supply for Canadian use. Close watch is being kept on this proposition because of the fact that it is being carried on with private funds and there has been no government subsidy. Officials of the United States have favored the policy of government subsidy and there are numerous plants now working under this arrangement. The Canadian project is expected to be a fair test of the advisability of allowing private interests to finance projects for the government.

Reports received here indicate that the Canadian plan will call for the adoption of the fabricated steel plan for ship construction. It is likely that efforts will be made to secure the adoption of plans for the Canadian ships which will correspond to the plans for the ships of the United States, in order that there may be the greatest speed in turning out the necessary fabricated parts. Word has also been received here that English shipyards are adopting the fabricated style of ship construction.

The 1919 shipbuilding program of the United States Shipping Board has been almost completely worked out. For military reasons the plans have not been disclosed but from statements made by Chairman Hurley it is generally estimated that the construction in 1919 will be in excess of 10,000,000 tons, the largest amount ever built by any one nation in one year. Before January 1 all of the new shipyards in the United States will have been completed. It is estimated that of the total tonnage about 8,000,000 tons of the program will call for steel vessels and 2,000,000 tons of wooden vessels. This is exclusive of any possible program for concrete ships which may be adopted following tests of a concrete vessel to be carried out next week. The working out of the 1919 program has been in co-operation with Sir Connop Guthrie, the British representative on the ship control committee. It is expected that of this program at least one-fourth will be turned out on the Delaware river. Admiral Bowles of the Shipping Board has estimated that the capacity of the eleven shipyards on the Delaware river will be about 3,200,000 tons.

A new record for construction of steel ships has just been established by the Skinner and Eddy plant in Seattle, Washington, with a record of 55 working days from the laying of keel to launching.

In order to speed up work the United States Shipping Board is now backing a great rivet driving contest among all ship workers. Reports of the records made each week are posted in every yard.

The fuel situation in the United States has not been generally alleviated yet. Reports come in of car congestion and mine owners from many states are reporting to the Fuel Administration that they are not able to produce to their full capacity because of the fact that they are not given sufficient cars. Every effort is being made by the Fuel Administration and the Railroad Administration to straighten out the difficulties in order that there may be no possible shortage next fall. The situation in the east is becoming better and the Fuel Administration is receiving reports which indicate that there is a general disposition on the part of manufacturers to lay in large stores of coal now for the winter season.

The appointment of John D. Ryan, prominent in the copper industry, to be in charge of all aircraft production in the United States has been well received both by the country and the industrial leaders. It is expected that the placing of a practical man of this sort at the head of the industry will give it a great ...

## HEAVY ORDERS FOR STEEL AND TOOLS

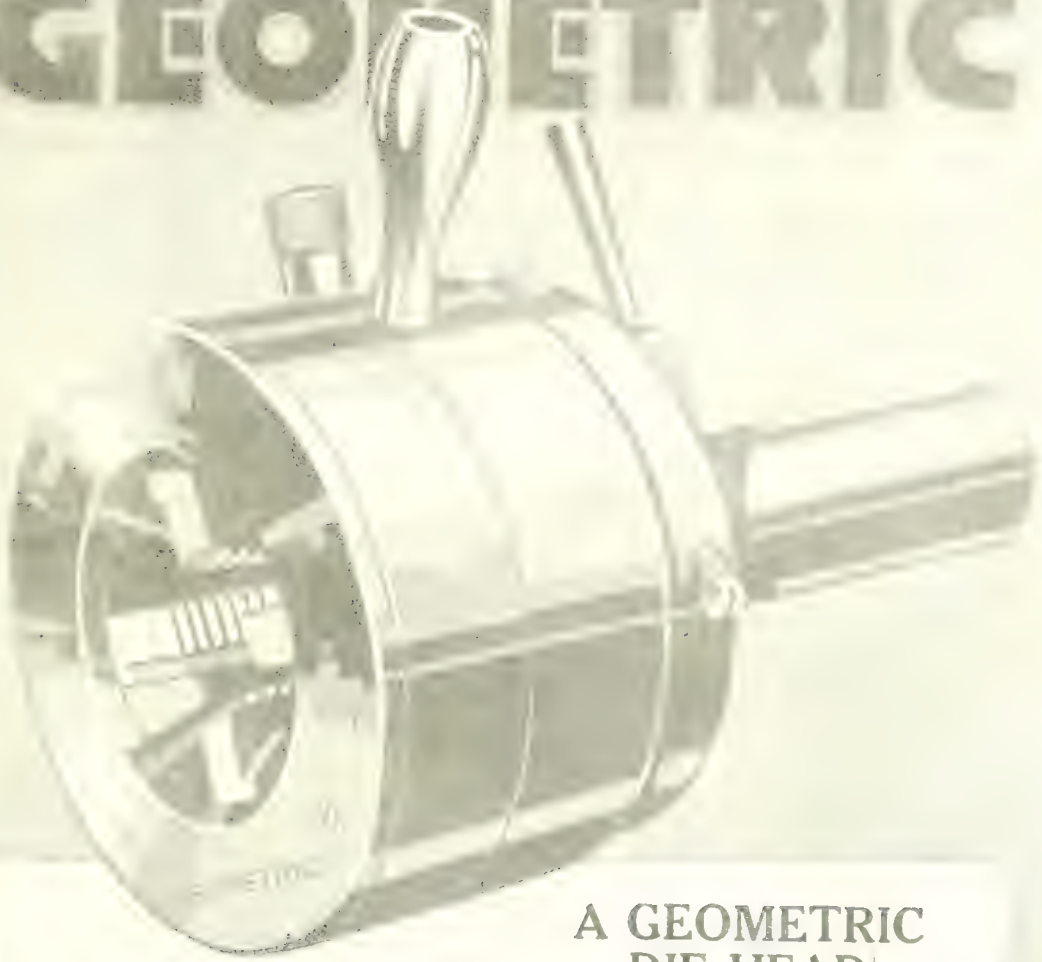
### U. S. Government Buying Machine Tools for Munitions Plants and Shipyards

Special to CANADIAN MACHINERY.

NEW YORK, April 27.—A most important meeting of the steel manufacturers and Government officials representing the War Industries Board was held at New York on Friday and supplementary conferences were held Saturday. No official information is available, but it is understood that the steel requirements of the U. S. and its Allies as detailed by the Director of Steel Supplies was most impressive. Heretofore, at least for the last month or so, war needs have absorbed 70 per cent. of the output of rolled steel and Government needs in the last ten days have grown to 80 per cent. Now it is understood that all commercial contracts will be held in abeyance until the pressing needs of the United States and its Allies have been satisfied.

It is estimated that in the next eight months, steel war needs will amount to 20,000,000 tons, including the manufacture of shells and ordnance, the building of ships and railroad equipment, and the production of wire products, pipe, structural steel and a host of other war munitions. Shell requirements alone are estimated at 6,000,000 tons. Ships, including merchant boats, naval warships for both domestic and foreign service, will amount to 5,000,000 tons, of which 3,000,000 tons will be required at home. Railroad equipment buying in its modified form will call for 4,300,000 tons. Structural steel requirements outside of the tonnage for ships, cars and locomotives will be between 750,000 and 1,000,000 tons. The needs of wire products, including barbed wire, nails, cold rolled strip steel, rivets, bolts and

# GEOMETRIC



## A GEOMETRIC DIE HEAD

### THE MONARCH OF THE SCREW-CUTTING INDUSTRY

For nearly a quarter of a century Geometric Die Heads have been steadily increasing production for the user and increasing business for themselves. Every Geometric Die Head sells another.

Inquire of the established users of Screw Machines and Power Lathes and get their opinion of the Geometric Die Heads.

Whatever your threading problem, there is a Geometric Die Head to solve it—in the most economical way.

Why should you not take advantage of the Geometric method of Screw Cutting? Whenever you are ready to take up your threading proposition with us, you will find us ready to advise with you.

## THE GEOMETRIC TOOL COMPANY

NEW HAVEN CONNECTICUT

Steel Production Increase

[illegible] now operating at the rate of 95 per [illegible] adequate transportation service the plants will be capable of turning out between 26,000,000 to 27,000,000 tons of rolled products during the remainder of the year, provided that all war requirements will be fully met if Government plans for ships, cars, motive power, ordnance and shells, and for military structures are not changed. Heretofore the mills have been seriously embarrassed by frequent alterations in Government orders which have [illegible] the drawing of new plans, the derangement of mill schedules and the discarding of many thousands of tons of steel previously rolled, resulting in expensive delays in the launching of boats and the manufacture of numerous kinds of war munitions and in the building of military structures.

In the last few days, there has been evidence of reformation which will result in expediting the building of ships and of railroad equipment and large orders for ordnance and shells, long delayed, are on the point of being placed. Contracts for projectiles aggregating $50,000,000 are now ready for distribution. Orders for 30,000 freight cars have been released and the Shipping Board has awarded contracts for 22 more merchant ships to Atlantic and Pacific coast yards and for 66 ships to lake builders.

### Machine Tool Buying

Buying of machine tools has been less active in the East, but there is still some activity in the interior. At Chicago the Pullman Co. has ordered $275,000 worth of shop equipment to be used in making 155 mm. shells. The Buda Co., Harvey, Ill., has placed large orders for machine tools and the Globe Stove & Range Co., Kokomo, Ind., has been buying machinery to execute a contract for trench mortar bombs. In New York, the Raymond Engineering Corp. has come into the market for lathes and milling machines to make gun sights for which it has received a $500,000 Government contract. The Ordnance Department of the Government has been buying machine tools for New England plants that are producing Browning machine guns. The Government has also been buying portable drilling machines at Cincinnati; most of these tools being for export to France and Italy. The Braden Copper Co. is also buying cranes and hoists for shipment to Italy. Shipyards have also come into the market for tools for many new plants now in course of construction.

## GOVERNMENT CONTROLS STEEL DISTRIBUTION

### War Demands More Urgent—Less Steel for Private Enterprises

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., April 30.—One of the most important actions for some time past taken by the War Industries Board is the request recently made to the steel producers to report in full detail the nature of the consumption involved in their commercial orders. The weekly reports that have been made to Washington for some time past, of shipments made during the week and of orders remaining on books, have divided the steel into three classes, that intended for the Government, that intended for the Government's allies, and that intended for the general trade. By means of order numbers or other description the precise character of the steel involved in the first two categories has been given. That in the third category has been given only in lump tonnages.

The object of the War Industries Board in taking fresh measures with regard to steel distribution appears to have been misunderstood in some quarters. At any rate the report that has been circulated, from Washington, that steel deliveries except for war work are to be shut off for the future, is contradicted in the steel trade. The steel manufacturers are in close touch with Washington. While some reports have referred to "nonessentials," their information is that Washington has tabooed the word "nonessential" entirely. No such thing, as regards steel, is recognized. There are "less essentials." Everything in steel is more or less useful, the gradations being in the degree of usefulness. In order to supply the information required by Washington, the steel makers are calling for reports from customers, detailing precisely the use to which the steel now on order is to be put. The authorities will eventually be able to formulate a complete list, showing the sequence of importance of all employment of steel. The conception that steel supply will be extended only so far down the list, as far as it will reach, and then stop absolutely, is erroneous. If there are 1,000 items in the list, and a 75 per cent. steel supply, it will not mean that the first 750 items will be taken care of and the remaining 250 items not get a pound. After a few prime essentials are fully taken care of, the allotment will decrease gradually as one goes down the list. Regulation will be by means of the coal distribution and the allotment of traffic facilities, already invoked in many instances, and through the distribution of steel itself, as defined by the authorities to the steel producers.

### Less Commercial Steel Shipments

Through the double influence of the Government calling upon the steel mills, some three weeks ago, for heavier shipments for shipbuilding and some other purposes, and of this more recent call for detailed information as to the intended employment of steel involved in commercial orders, there is a decrease in the shipments of steel for commercial purposes, not thus far distinguished by any consideration on the part of the Government. This decrease may be only temporary. Steel is scarcer than it was. Deliveries are more difficult to secure, against old orders, and it is still more difficult to place new orders. There is, however, no great clamor on the part of buyers. While there are urgent unsatisfied needs they do not relate to large tonnages.

### Freight Cars Bought

The Railroad Administration has begun to place orders against the program of buying 100,000 freight cars, the first order being placed last Friday, involving 30,000 cars to be furnished by the American Car & Foundry Co. While the specifications are withheld, it is known that the types adopted require less steel, particularly sheared plates, than was involved in the original plans. This is concrete evidence of the seriousness of the apprehensions entertained by the War Industries Board as to the supply of plates for shipbiulding.

As to steel for shipbuilding, an interesting piece of information is furnished by the management of the Hog Island yard, that the management estimates an average of 60 days for the time elapsing from the steel leaving the mill until it reaches the shipyard in fabricated form. The yard, which has 50 ways, some already completed, and will build ships of 7,500 and 8,000 tons deadweight, draws its fabricated parts from more than 35 shops distributed as far west as Minneapolis. Allowing three months from keel laying until the vessel is launched, and one month additional for completion in the fitting-out basin, there is a six months' interval from the time the steel leaves the mill until the ship is delivered. Accordingly, the rate at which ship steel must be produced now is not the rate indicated by the rate at which vessels have lately been completed or launched, which rate recent reports have shown to be such a disappointing one, but the rate that will be obtaining six months hence, and certainly a much higher rate.

### Production

There has not lately been any further increase in the rate of production, in general, of pig iron, of ingots, or of finished steel. The rate as a whole is about 85 per cent. of capacity, which is about the average rate maintained since March 1. Production at this rate, however, means substantially as great a tonnage as was produced in 1916, when operations were practically at capacity. The difference is accounted for by the new construction that has been carried through since. So much has been said about the inability of the industry to operate at capacity that there is danger of a distorted view being created, through the 15 per cent. that is not being produced being emphasized, rather than the 85 per cent. that is being produced. As a matter of fact, this production is about equal to the largest

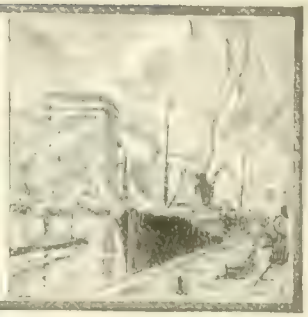
NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES



## ENGINEERING

Higher Express Rates Wanted. At Guelph, Ont., The Grand Trunk Railway, Limited, has applied to the Hydro-Electric Power Commission of Ontario for permission to put in effect higher express rates between points in the Hydro Electric District.

Chesley, Ont.—Fire destroyed the machine shop and power house of the Canada Bolt, Nut & Rivet Co., Ltd. It is estimated that the loss will be about $40,000.

**Toronto, Ont.**—A roundhouse, coaling plant, ice house, etc., will be built by the C. N. R. at Leaside Junction. The architect is G. C. Briggs, 27 Wellington street east, Toronto.

**Montreal, Que.**—With the plate mill contract and other orders recently closed, it is understood that Dominion Steel Corporation has recently put some $30,000,000 new business on its books.

**Fort William, Ont.**—The Nipigon Reserve Iron Co., has opened an office here with J. W. Newcombe in charge. The company, which is capitalized at $375,000 will develop 200 acres of iron land in the Nipigon district.

**Hull, Que.**—The British American Nickel Co. has purchased the property known as the old Conroy piling grounds at Deschenes, upon which a nickel refining plant, to cost in the neighborhood of $1,000,000, will be erected.

**Welland, Ont.**—The Volta Mfg. Co. will build an addition to its plant here. The extension will be 50 feet by 50 feet, of brick construction, and will be used as a machine shop. The company manufactures electric hoists and electric furnace controllers.

**Montreal, Que.**—S. M. Roberts, of this city, has been appointed president and general manager of the Grain Growers' Auto Tractor Co. It is the intention of the company to manufacture tractors in Canada, and a site may be purchased in Ontario.

**Toronto, Ont.**—The Galena Signal Oil Co. intend to rebuild their plant at once, which was recently destroyed by fire. The general contractors, Archibald & Holmes, Excelsior Life Bldg., are receiving quotations for scrap steel tanks, piping, etc.

Cobourg, Ont.—The Imperial Muni-

purposes, it is said. Work on repairing

M. Jak & Co. have the contract.

be shipped into the Canadian West. Winnipeg will receive a small supply, but western points must depend upon the domestic supply. This decision is said to have been reached at a conference between Western coal operators and Fuel Control officials at Ottawa recently.

**Montreal, Que.**—The Canadian Car and Foundry Co. is operating with the Manitowoc Shipbuilding Co. of Manitowoc, Wis., in the manufacture of twelve mine-sweepers for the French Government. Work has already been started on the shipyard which is located at Fort William. The plant will cost about $200,000.

**Hull, Que.**—The Hull Iron & Steel Foundries, Ltd., is building a new cleaning department with all necessary air hammers, clippers, grinders, etc., also new annealing ovens, together with electric and oxy-acetylene welding outfits. This building will be 100 ft. by 300 ft. long, with private siding for all outgoing shipments. The company has just put into operation a six-ton electric furnace, using a 1,200 k.v.a. transformer and special automatic regulating equipment for raising and lowering electrodes.

**Montreal, Que.**—To aid fuel conservation the Bell Telephone Co. intend to make some changes in their power plant at the head offices in Montreal during the early summer. A steam turbine will be installed to operate the pumps that generate the power for the hydraulic elevators; one of these will be changed over to be run by electric power. Their electrical power is now generated by Robb horizontal steam engines; these are to be replaced by motors, belt connected to the generators.

**Quebec, Que.**—Plans for the erection of yards, shops, sidings, etc., covering over two square miles of ground, near the Quebec bridge, are under way, and so far in the little parish of Charny, County of Levis, a couple of miles off the south side of the St. Lawrence, options have been taken on most of the ground that will be used for the erection of said plants. This would mean the co-operation of eleven railroads, both American and Canadian, in the erection of fthe said yards and shops. The whole enterprise would mean the spending of over seven million dollars.

**Victoria, B.C.**—The mirror for the telescope located at Observatory Hill, near here, has arrived from Pittsburg, and will be installed in the course of the next few weeks. It is 73 inches in diameter and weighs two and a quarter tons, and is the second largest mirror in the world, the largest being the one-hundred-inch lens made for the observatory at Mount Wilson, California. The mirror was made in Belgium, and left Antwerp one week before war was declared. It was ground in the workshops of Dr. John A. Brasser, of Pittsburg, the operation taking three and a half years.

**Boston Creek, Ont.**—Underground developments continue highly satisfactory at the Patricia Syndicate property here. It is anticipated the work of installation of the new mill will be completed by the last week in May. It is less than six months since the first ground was broken on this property, and with the erection of the mill and commencement of production by the end of May, a new record will be established in mine operation in the North Country. The capacity of the new mill for which the equipment is now on the ground, will be between 50 and 60 tons per day. The machinery consists of the following: 5 x 9 Blake crusher, 5 ft. x 6 ft. Allis-Chalmers ball-granular, classifier, amalgamating plates and Wilfley tables.

**Hamilton, Ont.**—Officials of the Steel Company of Canada are making efforts to secure coal mines of their own so that they will not have a recurrence of the trouble experienced last winter in getting coal supplies. This follows the important success of the company in purchasing iron ore deposits. It is vital that the big Canadian steel industries have their own raw materials if they are to wage successfully the post-bellum commercial wars. F. H. Whitton, the general manager, stated recently that there would be no difficulty in placing the entire 1918 output. He pointed out, however, that prices for most products would probably be lower and cost would be higher, wages already having been advanced. The company contemplate making considerable extensions to the plant this year.

## ELECTRICAL

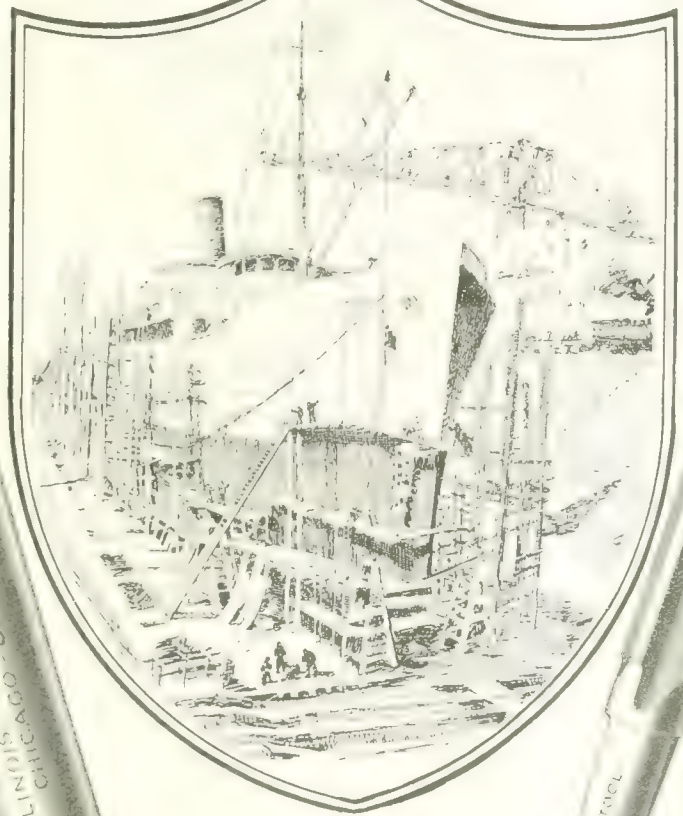
**Sherbrooke, Que.**—The City Council will call for tenders shortly for an electric distributing station.

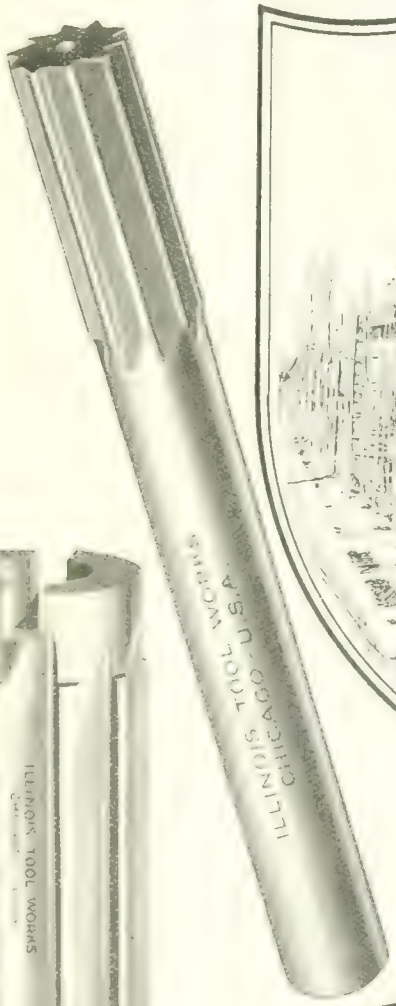
## MUNICIPAL

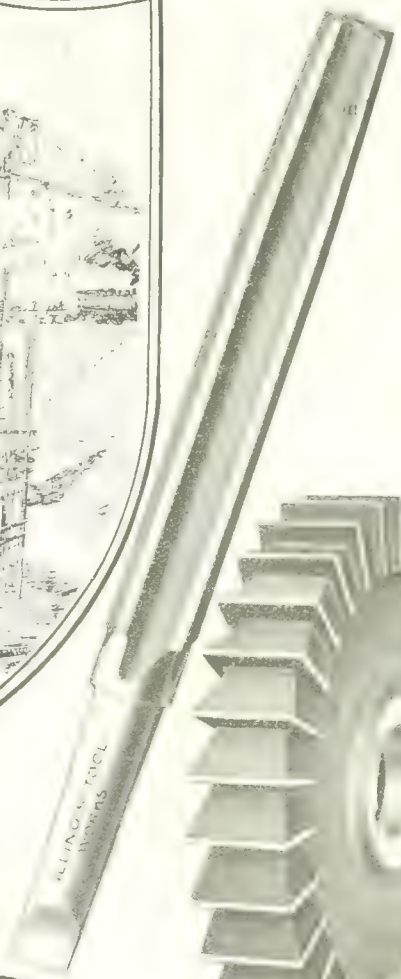
**Cobourg, Ont.**—The Town Council will ask the Federal Government to repair the breakwater at an estimated cost of $7,000.

**Lachine, Que.**—Tenders are being received for cast iron pipe and specials.

# ILLINOIS TOOLS







In the shipyards of the Pacific coast, the Atlantic seaboard and the Great Lakes,

## "ILLINOIS" BRIDGE AND BOILER REAMERS

are being used in constantly increasing numbers to expedite the building of ships—freighters, transports and dreadnaughts. Standard Cutters and Reamers in stock. Punctual delivery on specials. Write or wire for quotations.

## ILLINOIS TOOL WORKS, CHICAGO.

[illegible] from the [illegible]

[illegible] Ont.—A [illegible] will be [illegible] May 6, [illegible] of $25,000 to the Huntley Mfg. Co., to assist in the reconstruction of the factory which was destroyed by fire.

[illegible] Ont.—Council will accept [illegible] submitted by the Hugh C. Cameron Co., in spite of the fact that it does not comply with the requirements of the Fire Marshal, as it has been shown that the apparatus was built according to specifications supplied by Fire Chief Smith.

**Winnipeg, Man.**—The Manitoba Government has tentatively decided that [illegible] shall be a city of automatic telephones, it has been authoritatively announced. The change will be made gradually, the whole Winnipeg system will probably not be automatic before five years, it is declared.

**Comber, Ont.**—Tenders will be received by S. T. Anderson, township clerk, Comber, Ont., up till May 10, 1918, for the construction of two concrete bridges over the west branch of Big Creek, in the township of Tilbury West. Plans and specifications may be seen at the office of S. T. Anderson, clerk, Comber, or J. J. Newman, C.E., Windsor.

**Mimico, Ont.**—By-laws to raise $28,376 were passed by the Mimico Town Council at its meeting in the public library. Of the total, $16,460 is for sewers and $11,910 for waterworks purposes. Council deferred decision on the purchase of motor fire truck and decided to ask for tenders from various concerns before accepting one for $1,600 on a motor chemical truck.

## GENERAL

**Toronto, Ont.**—Fire completely destroyed a warehouse of the Hortop Milling Co., 47 Shaftesbury Avenue, Saturday night, and spreading to the adjoining buildings on either side damaged the storehouse of Risburg and Jackson, hay and straw merchants, and the North Toronto branch of the Western Canada Flour Mills Co. The damage to the Hortop building and contents is placed at $3,000, while a similar amount is estimated to that of the Western Canada Flour Mills branch.

## PERSONAL

**N. W. VanWyck** has been appointed purchasing agent of the Canada Steamship Lines at Montreal, vice P. Paton, resigned to engage in other business.

**John Reekie**, office manager of the Chapman Double Bearing Co., Sorauren Ave., Toronto, has just recovered from a dangerous attack of pneumonia and is now well enough to resume his duties.

**Albert Deschamps**, of the Atlas Construction Co., Montreal, and one of the engineers in charge of construction in the building of the concrete boat "Concretia," is about to leave on a vacation of several weeks into Northern Ontario.

**Harry M. Marsh**, for the past six years Commissioner of Industries and Publicity for the City of Hamilton, resigned that office on April 1. **C. W. Kirkpatrick**, well known newspaper man, was appointed by the City Council to the position and assumed his duties on April 15.

**H. L. Peiler**, general manager of the Mason Regulator and Engineering Co., Ltd., Montreal, has received word that his son, Second Lieutenant Maurice F. Peiler, R.F.C., is a prisoner, unwounded, in Germany. He had previously been reported missing on April 6.

**R. D. Smith** has recently been appointed to the position of Steam Superintendent for the Wayagamack Pulp Mills at Three Rivers, Que. Previous to his leaving for Three Rivers, Mr. Smith was chief engineer at the Windsor Station, Montreal, Que.

**Pte. Harold F. Fogarty**, formerly on the editorial staff of CANADIAN MACHINERY, is in a hospital in France suffering from a gunshot wound in the chest. Pte. Fogarty went overseas with the 198th Battalion early in 1917, but was later transferred to another unit. His home is in Port Hope, Ont.

**U. Valiquet**, M. Can. Soc. C. E., who is Superintendent of Public Works at Ottawa, was to have read a paper on the "Champlain Dry Dock for Quebec Harbor," but owing to illness and urgent business at the capital was prevented from attending the last meeting of the Society of Engineers. In his absence the paper was ably presented by F. H. McGuigan, jr.

**C. G. Bowker**, of Montreal, who has been superintendent of the G.T.R. eastern lines for five years, has been appointed to the position of general superintendent of Ontario lines with headquarters in Toronto. Mr. Bowker has been in railroad service for thirty years, starting his career as a telegraph operator. He has been with the Grand Trunk Railway System as train despatcher, chief despatcher, trainmaster, assistant superintendent and superintendent.

**Lieut.-Col. C. N. Monsarrat**, chairman of the Quebec Bridge Commission, is at present in Montreal arranging for the transfer of the commission's offices to Ottawa for the work connected with the winding-up of its activities, which will probably take about a year. The offices will be moved to Ottawa within a short time. In addition to his work with the Bridge Commission, Lieut.-Col. Monsarratt has been appointed consulting engineer to the railways department of the government.

## TRADE GOSSIP.

**Montreal.**—At the annual general meeting of the Canadian Express Co., held in Montreal recently, the president, Howard G. Kelley, stated that it might be necessary to ask the railway board for permission to increase its rates.

**Acquire Zinc Concentrates.**—A report from Melbourne, Australia, states that the British Government has contracted for the purchase of virtually the whole product of Australian zinc concentrates for the period of the war and a decade thereafter.

**Build New Plant.**—The firm of Fred Thompson Co., Ltd., has recently constructed a new three-storey and basement brick building to take care of their increasing business. This firm is manufacturing all kinds of electrical supplies; the new location is at 9 St. Genevieve St., Montreal.

**Bromption Pulp and Paper Co. Purchase Mill.**—It is understood that the Brompton Pulp and Paper Co. has made another addition to its property through the purchase of a sulphite mill at Holland, Maine. No official announcement of this purchase has been made as yet, but it is expected within a few days.

**The New Brunswick Power Co.** has during the past year made extensive additions to its plant, $72,112 being spent on power house, $14,543 on new railway equipment, and $11,803 for replacement of special work. In addition to this $24,477 was spent on additions and extensions in the electric and gas departments.

**Australian Importations of Galvanized Sheets.**—The average annual importation of galvanized corrugated iron into Australia during the past four years was 950,000 hundredweight, and importations of galvanized iron, not corrugated, were in the neighborhood of 800,000 hundredweight. Great Britain supplied over 90 per cent. and the United States most of the balance.

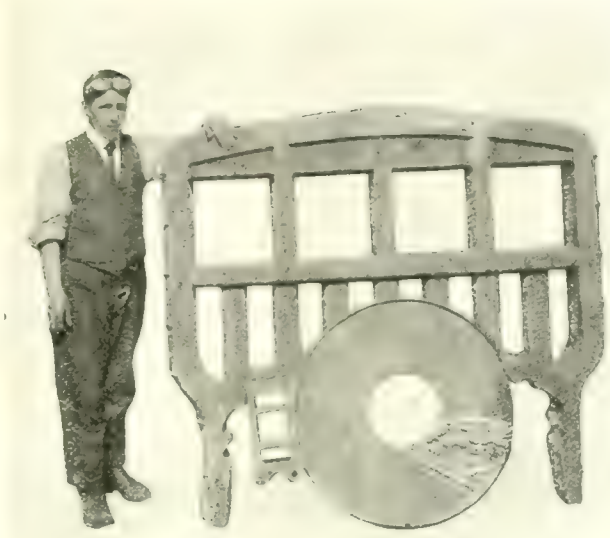
**Filling Big Orders.**—The National Steel Car, Hamilton, has completed shipping 1,000 cars for the Canadian Government railways. This will be followed up with 200 cars for the Bengal and Nagpur Railway, India. It is expected that another thousand cars will be completed for the Canadian Government railways. Twelve locomotives are in the process of construction for the Hydro-Electric.

**The Abitibi Power and Paper Co.** is one of the largest companies engaged in the production of newsprint paper and sulphite and ground wood pulp. Its mills are located at Iroquois Falls, Ont., and have an annual capacity of 62,000 tons of newsprint paper, 21,000 surplus tons of sulphite pulp and 22,500 surplus tons of groundwood pulp. The company controls under lease over 1,000,000 acres of pulpwood.

**Cuba Very Prosperous.**—Business conditions are wonderfully prosperous throughout Cuba, according to Sir Herbert Holt, president of the Royal Bank of Canada, who returned recently from a trip to Cuba, where he inspected the bank's branch system. He said there was probably as much building going on in Havana at the present time as in the whole of Canada. The boom in sugar has stimulated development to a wonderful extent.

**More Contracts Placed for Ships in U. S.**—Another U. S. Government-owned shipbuilding plant will be constructed on the Atlantic coast, in fact preliminary work has already begun at Wilmington, N.C., where the Carolina

# Saved by Oxy-Acetylene Welding



These two Boiler sections were quite unserviceable until the damaged parts were welded, which restored them to use again in condition equal to new.

There is no necessity to scrap broken parts of machinery, etc., paying exhorbitant prices and waiting weeks for replacements, and having your plant "tied up" in the meantime.

# Chilled Iron Dies
**for making**
## 75-mm. Shell Forgings

Chilled Iron Dies are harder on the wearing surface than tempered steel. The best cold chisel will make no impression on its wearing surface. But back of the hardened or chilled portion the metal is soft and easily machined. That is why it is the best material for these Dies.

In addition to the Nosing Dies we now make

DRAWING DIES
PIERCING DIES

for shaping the forgings for making 75-mm. shells.

Let us quote you on these for use in your shops.

---

## Marsh Engineering Works, Ltd.

U. S. A.

STERILIZED WIPERS
NO LINT
E-PHILAN WASTE CO. TORONTO

KINDLY MENTION THIS PAPER WHEN WRITING ADVERTISERS

Shipbuilding Corporation has secured a site on deep water to construct large steel ships. A contract has been signed for twelve 9,600-ton steel ships to cost approximately $[illegible],000,000. To save time the entire [illegible] ships will be built [illegible] the Federal Shipbuilding Company for the Emergency Fleet Corporation.

**Conserve Natural Gas for Domestic Uses.**—After hearing W. R. Nickle, a Government expert, explain the natural gas situation in Western Ontario, more than [illegible] municipalities of Western and adjacent border cities passed resolutions endorsing the Government's plan to conserve natural gas for domestic consumers by cutting off factories from the supply. It was decided, however, to send a recommendation to the Ontario Railway and Municipal Board to allow manufacturers the use of gas in small quantities for certain processes until a supply of artificial gas is available.

**Canadian Railway Earnings Increase.**—Railway earnings of the three principal [illegible] for the first week of April show increases, as compared with the same period in 1917. In the case of the Canadian Pacific Railway earnings for the week ending April 21 were [illegible], a gain of [illegible] per cent. over the same week last year. Grand Trunk earnings were $1,085,972, the increase amounting to $273,941, or 25.24 per cent. The total for the third week in April earned by the Canadian Northern was at $929,500, or $163,900 more than last year. The percentage of increase was 21.42 per cent.

**New Patents Issued.**—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge street, Toronto, from whom further particulars may be obtained: Wm. Ross, centrifugal pump; McDonald & Willson, Limited, indirect lighting fixtures; Borden Milk Co., liquid measuring and container charging machine; J. Stone & Co., apparatus for controlling the order or sequence of operations of mechanical devices, particularly valvular devices, employed in ships' ash expellers; Soren C. Jensen, safety device for small firearms; Fred Gilbert, bronzing apparatus; Robert R. Jackson, tire inflator.

**New Ferrosilicon Plant in Quebec.**—Walter Sharpe, 314 Grand Allee, Quebec, has the general contract and the Eastern Canada Steel & Iron Works, Ltd., the steel contract for the erection of a ferrosilicon plant at Beaupre, Que., for the Laurentian Power Co., Seven Falls, Que., to cost $300,000. The plant will be of brick and steel construction, and will have three furnace rooms, each 15 x 50 ft. The electric station for supplying the furnaces with power will be 20 x 160 ft. It is exepected that the plant will be completed and in operation within three months. The company has a large contract with the Imperial Munitions Board. The plant will have a capacity of from 12 to 15 tons per day.

**Price Bros. & Co. Develop Plants.**—Sir William Price, president of Price Bros. & Co., in his report states that a new unit was added to the Kenogami mill during the year, bringing the capacity up to 200 tons of newsprint a day, while the Shipshaw Power development was also completed and is supplying the company with 10,000 h.p. The development includes a storage dam with a capacity of nearly seven billion cubic feet. As to general conditions, the president says: "The pulp and paper branches of the business have been somewhat hampered in their operations and supplies, and difficulties experienced in procuring necessary transportation for the finished product."

**East and West Coal Production.**—At a conference at Ottawa recently the Western coal operators stated their ability to increase the production of bituminous coal by 1,280,000 tons and of lignite coal by 1,225,000 tons. The figures would not hold good unless the same amount of labor was available as last year, and unless the railways were able to furnish transportation required. The memorandum of the Nova Scotia operators stated that the production of Nova Scotia mines had been estimated at 5,950,000 tons, but the production actually attained was 5,660,000 tons. The operators reported a considerable improvement in transportation facilities.

**Emergency Fleet Corporation Orders More Ships.**—The biggest contract for ships ever placed on Great Lakes was booked recently by American Shipbuilding Co. The order was placed by the Emergency Fleet Corporation, and calls for sixty-six steamers for salt water service for delivery in 1919. Something more than 90,000 tons of steel will be used in their construction, and they will cost more than $50,000,000. The steamers will be full Welland Canal size, but sixty of the boats will be deeper than the freighters of that class now being turned out. Six of the steamers will be 22 ft. 6 ins. deep and will have 3,500 tons capacity, and six will be 28 ft. 2 ins. deep, with 4,200 tons capacity. The boats will all be 261 feet long and 45 ft. 3 ins. feet beam.

**More Ships From Lakes for Ocean Trade.**—A dispatch from Washington states that thirty-four new ships of 105,000 tonnage, completed during the winter and spring in Great Lakes yards, will begin moving to the Atlantic shortly for service overseas. No alterations will be required for the ships to pass through the locks. Cargoes are being put aboard for the voyage east. All of the vessels were requisitioned by the United States Shipping Board in the early stages of construction. They were designed for overseas trade and are of the Frederickstadt type, 3,100 tons, 261 feet over-all, 43 ft. 6 in. beam, and 20 feet depth. Before the ice season set in the Shipping Board moved forty-three ships, including twenty-four of new construction, from the lakes to the ocean.

**Big Nickel Merger Contemplated.**—The amalgamation of the International Nickel Co. of Canada and Canadian Copper Co., of Sudbury, Ont. in a fifty-million-dollar concern, with the ultimate purpose of making Ontario not only the dominant producer of nickel ore, but the centre of the world's nickel refining industry as well, is stated to be the plan upon which those interested in the industry are now working. No official confirmation of the report is available, but Mr. Britton Osler, provisional director of the International Nickel Co. of Canada, admitted that the increase in the company's stock from $5,000,000 to $50,000,000, which was approved at Ottawa recently, was "suggestive." The circumstances in connection with the increase in the company's capital indicate that important plans are under consideration. The International Nickel Co. of Canada came into existence on July 25th, 1916. The International Nickel Co. is building a large refinery at Port Colborne, Ont.

**Quebec Railway Prospects Favorable.**—Satisfactory progress is being made in the work of completing the Quebec and Saguenay Railway. When work on the line was shut down last fall rail had reached to within three miles of [illegible] track-laying was recommenced, and in early May the rails will be at Baie St. Paul, while it is estimated that the rails will reach Murray Bay towards the end of July. All the heavy work on the whole line has been completed, and probably in excess of 90 per cent. of the total work of grading has been done. The end of this summer, therefore, should see a train service established between Quebec and Murray Bay. At Baie St. Paul, a titanium ore mine has been operating for a number of years, and no doubt now that the railroad is approaching completion the owners of the mine will build a spur line of nine miles so as to be able to get out their product by rail. There are [illegible] of pulpwood and considerable lumber in the district. Something like 100,000 cords of pulpwood which now come down every year to Baie St. Paul will in future be taken to destination by rail. At Murray Bay there is the pulp mill of the Nairn Falls Power and Pulp Co., which is a new and up-to-date plant that will supply considerable freight for the road.

## TENDERS

**Melbourne, Australia.**—Tenders will be received until June 6, 1918, by the Commonwealth Railways Commissioner, Department of Works and Railways, Melbourne, for the manufacture, supply and delivery of material for ten "G" class locomotive boilers.

**Melbourne, Australia.**—Tenders will be received until July 3, 1918, for the following electrical instruments for the Victorian State Railways: Eleven integrating wattmeters, 500 amps; six integrating wattmeters, 100 amps; four integrating wattmeters, 50 amps.

**Telephone Equipment Wanted.**—Tenders will be received by the Deputy

Postmaster-General, Melbourne, Australia, until July 2, 1918, for the following materials: 153 tons galvanized iron wire, as specified; 456 tons, 1 cwt. 3 grs. copper enamelled wire, as specified; 57,350 copper jointing sleeves; 3,975 telephones, as specified; 5,500 stalloy diaphragm receivers, as specified, schedule numbers 1436 to 1450 inclusive.

**Windsor, Que.**—Tenders will be received by the undersigned until May 25, 1918 for the reconstruction in cement of two piers of the Windsor and Brompton Bridge, crossing the River St. Francis, between the municipalities of the town of Windsor and of the parish of St. Francois Xavier de Brompton. Plans and specifications of said piers are deposited with the undersigned and can be seen at any time at his office. J. A. Lagasse, secretary Windsor and Brompton Bridge Committee, Windsor, Que.

## BUILDING

**Woodstock, Ont.**—The Standard Tube & Fence Co., of Woodstock, is building a warehouse, 125 feet x 52 feet. Concrete is being largely used in the work of construction.

**Georgetown, Ont.**—A serious fire occurred here last Thursday, when the Georgetown "Herald" plant was completely destroyed and the building badly gutted. The loss on the newspaper plant will be $5,000, and on the building $3,500, partly covered by insurance.

## CONTRACTS

**Renfrew, Ont.**—The Roberts Filter Mfg. Co., Philadelphia, have the contract for filters costing $6,000, for the City Council.

**Springfield, Ont.**—The Canadian Ice Machine Co., Toronto, have the contract for refrigerating plant for the Springfield Milk Co., who are receiving prices for the supply of piping for water, steam and air.

**The Dominion Bridge Co.,** Montreal, have received an order from the Dominion Government for eight 2,500 h.p. marine steam turbines; these turbines are to have a speed reduction from 3,500 to 100 revolutions per minute.

**Toronto, Ont.**—The Board of Control has carried the report of Commissioner Harris to accept tenders from the Drummond, McCall Co., to supply steel poles for the Bloor Street viaduct at a cost of $5,467.88. The department will need twelve 30-foot poles, forty 28-foot poles, and twenty-one of 24-foot length. Pole accessories costing $766.65 will also be bought in this connection.

**Ottawa, Ont.**—The tender of E. W. Edge, Ltd., Ottawa, for the heating and ventilating equipment for the new parliament buildings at Ottawa has been accepted. Their figure, at $386,000, was the lowest submitted, all others exceeding $400,000. McFarlane-Douglas were the successful tenderers for the bronze-covered frames and sash, at $32,500, and the Otis-Fensom Elevator Co. got the contract for equipment for two elevators, at $31,940.

## MARINE

**Gananoque, Ont.**—The lighthouses in this district of the Thousand Islands are in operation.

**Toronto, Ont.**—It is understood that the Dominion Government will spend $425,000 on harbor improvements here and not $550,000 as previously reported.

**Kingston, Ont.**—It is understood the Kingston Shipbuilding Co. has work ahead for a considerable time and some big vessels will be built.

**Levis, Que.**—The Davie Shipbuilding & Repairing Co. will build dry dock sheds at a cost of $600,000. The Dominion Bridge Co. have the steel contract.

**Sarnia, Ont.**—The sand barge Ontario and tug Annie Moiles are employed deepening the channel leading from Sarnia Bay up to the Dominion Salt plant. The work is necessary to enable coal boats to carry full loads to the works.

**Montreal, Que.**—Good progress is being made in fitting out the "Concretia," the concrete vessel lately constructed by the Atlas Construction Co. Work is now nearly completed on the superstructure, and it is anticipated that the boat will be ready for her trial trip within a few weeks.

**Sarnia.**—The plant of the Reid Drydock Co. at Port Huron has been taken over by the Foundation Corporation of New York, and the works will be greatly increased in size. The new company has a contract for building a fleet of steam trawlers for the ocean and also small war vessels.

**Vancouver, B.C.**—Sponsored by Mrs. W. E. Collings, of Seattle, the ship War Haida was launched from the Cameron-Genoa shipbuilding plant last Friday. The ship is the second to be launched of the four wooden steamers the Cameron-Genoa Mills Ship Builders, Ltd., contracted to build for the British Government.

## RAILWAYS

**Vancouver B.C.**—At an expense of one million dollars a branch of the Kettle Valley Railway from Princeton to Copper Mountain will be extended this year. The branch line will be fifteen miles in length.

**Victoria, B.C.**—The provincial railway department has been advised by the United States Steel Corporation that shipments of steel rails for use in extending the P. G. E. will commence within the next 30 days. The steel rail shipments will total 20,000 tons and will arrive at the rate of 1,500 tons per week. Ten thousand tons will be sent over the Grand Trunk to Prince George, to be laid southward from that point, and the other 10,000 tons will be sent to Squamish. The work of laying rail will commence at both ends of the route.

**Bridgeburg, Ont.**—The New York Central, Toronto, Hamilton and Buffalo and the Canadian Pacific Railway are behind the project to build a general traffic bridge across the Niagara River near Bridgeburg. An application for a charter will

be made to parliament this session. The provisional directors of the Canadian-Niagara Bridge Co. include A. H. Smith, president of the New York Central lines, and Lord Shaughnessy, president of the C.P.R. It is assumed that it is planned to build the bridge at a point about two miles below Bridgeburg, where surveys were made two years ago.

## CATALOGUES

**Metlskin Boiler Preservative.**—A folder giving particulars of the Metlskin boiler preservative manufactured by the Metlskin Co. of Rochester, N.Y. The Canadian Fairbanks-Morse Co. are the Canadian distributors.

**The Link-Belt Co.**, Chicago, Ill., has recently distributed a new publication, No. 359, entitled "Chain Driven Motor Trucks and Tractors." The bulletin describes in detail the principal features and advantages of the Link-Belt chain-drive. It also contains particulars of the chain and a number of illustrations of tractors and trucks equipped with the chain drive.

**America's Airplanes** is the title of an interesting book published by the Gisholt Machine Co., Madison, Wis., giving a brief pictorial history of aircraft development and showing how the Gisholt turret lathes are used to manufacture some of the mechanical parts. The first section illustrates a few of the more notable airplanes and hydro-aeroplanes, showing the development that has been made in the design of aircraft. The second section shows the Gisholt turret lathes and how they are tooled for the various operations for producing some of the more important mechanical parts. This section includes the operations performed for the production of cylinders for Gnome engines.

### PITTSBURG MARKET LETTER

(Continued from page 80.)

output ever made before the war by the original belligerents, Britain, France, Russia, Germany and Austria-Hungary. It is materially in excess of the tonnage these countries actually made during the first twelvemonth of war. Were only 50 per cent. of the United States output passing to war use, the contribution would be a very large one, but the proportion is undoubtedly higher than 50 per cent.

The chief restrictive influence is the insufficient car supply in the Connellsville coke region. For three successive weeks the reports of the *Connellsville Courier* have shown slightly decreasing shipments. There is probably a normal number of cars in the service, but they do not make the round trip as expeditiously as in 1916, for instance. Thus supplies of Connellsville coke have been less in April than in March, rather than greater. The by-product coke ovens, however, have done somewhat better this month, and have been operating substantially at capacity.

Lanco Balata Belting

is now one of the most expensive belts in the market.

When the cost of raw material increased the price of this belt to where it is to-day, we were a little afraid that it would result in a diminution of our sales. We have been very agreeably disappointed the sales have not dropped off.

There are cheaper belts on the market that will give as good service but not for so long. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the plies tightly together, is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that, as far as we know, has never been equalled by any other gum. The duck is of course stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions, except those of heat, it will give a length of service that makes its price worth while.

# Hendey Experimental 12" Lathes

For the Laboratory or Experimental Department where the best of its kind is wanted, and each machine must be motor-driven, here is the Lathe in this HENDEY 12".

In addition to its complete regular equipment it has Small Tool Cabinet for operators' fine tools, also gear closet for extra gears to cut special threads.

# FORGING BLANKS FOR 6 in. AND 75 mm. SHELLS

BY
A. G. Webster

ALTHOUGH the Cluff Ammunition Co.'s forging plant has been in operation for some time, more recently extensive alterations have increased its capacity and scope. Experience gained formerly has also enabled the production to be materially increased. The company is now making 6-inch and 75 m m. forgings, the latter for the American Government. There has also been installed a plant for re-treating or heat treating forgings which have been rejected on account of their not being up to tensile test requirements. By means of this treatment many forgings are ultimately used which otherwise would be scrapped. The capacity of the re-treating plant is such that forgings from other shops in the district can be treated in addition to those rejected at the Cluff plant. This plant is an interesting feature of the company's activities and is one of the more recent developments in the munitions industry.

As will be noted later, the layout of the forging plant is so arranged that there is a minimum amount of wasted effort from the time the billets leave the cars until the forgings are shipped. From the piles to the furnaces, then to the presses and so forth, each operation follows the other in regular sequence without any lost motion, the steel going forward all the time until the product is shipped. In this connection a great deal of time and labor is saved by means of a gravity conveyor. This conveyor, which runs parallel to the line of presses, and along the cooling floor, carries the forgings direct from the presses to the cooling floor and afterwards to the cars for shipment. The carrier was supplied by the Canadian Matthews Gravity Carrier Co., Toronto.

### Heat Numbers Kept Separate

An important feature in the operations at this plant is the care which is taken in treating and keeping together all billets and forgings, as the case may be, according to the heat number. It is of

*Associate editor Canadian Machinery.

[illegible] AND DRAWING 75 MM. FORGINGS SHOWING CUPPING OPERATION.

course well known that each billet is stamped with a certain heat number before being shipped from the steel plant. This heat number is retained throughout the various operations which are regulated according to the analysis of the steel. In the first place the billets are removed from the cars, under cover, and piled on the floor according to the heat numbers. The billets are not mixed together but are arranged in separate piles, each pile comprising billets of a uniform analysis. The piles are situated at the back of the furnaces and [illegible] lets. A 6-inch billet weighs about 158 pounds, is 17¼ inches long and 6½ inches diameter.

### Furnace Installation

The furnaces are of the continuous type, receiving the billets direct from the piles at the back and delivering at the front end to the presses. There are nine furnaces altogether arranged in one long row, two furnaces are used in connection with the 6-inch presses and the other three for the 75 m.m. presses. They can however, be used either for the 6-inch [illegible] of the situation. The furnaces are oil fired, the oil pressure being 40 pounds and air pressure 10 ounces. Each furnace has a capacity of about 75 6-inch or 250 75 m.m. billets at one charge. The front end of each furnace is equipped with a water curtain to protect the men from excessive heat, particularly in the summer time. The device consists of a sloping galvanized sheet covering the entire furnace front with the exception of the place left for removing the billets. A perforated pipe runs along the top of the galvanized sheet, distributing cold water, which runs down on the inside and is collected in a trough at the bottom, thus forming a curtain dissipating considerable heat and making the work less arduous for the men. The water supply is part of the circulating system which is also utilized for cooling the punches and dies in the presses.

An interesting system is seen here in connection with the furnaces for recording the heat in each furnace. Each furnace has a pyrometer for ascertaining the heat in the furnace. The pyrometers are all connected to two tapalogs installed in an office in the forge-shop, one tapalog being connected to furnaces No. 1 to 4 inclusive and the other No. 5 to 9 inclusive. The tapalog gives a continuous record for 24 hours, different colored inks for the various furnaces being used for marking the charts. The tapalogs and pyrometers were supplied by the Wilson-Mauler Co., New York City.

### Six-inch Shell Forgings

The plant for producing the forgings for the 6-inch shells comprises three 500-ton "Southwark" hydraulic presses giving a production ranging from 900 to 1,000 forgings in twelve hours. The billets are heated in continuous furnaces already described, each furnace having a capacity of about 75 billets. The billets are kept in the furnaces about 1½ to 2 hours, the time varying according to the speed of operation at the presses. The temperature in the furnaces ranges from 1,900 to 2,200 degrees Fahr., according to the carbon content of the steel. The billets, while being heated, are turned over five or six times to ensure their being heated uniformly. The billets after being drawn from the front end of the furnace are scaled and then lifted to the presses by means of tongs suspended from an overhead runway. It is essential that the scale should be removed otherwise the dies might be damaged and it might also prevent the steel from drawing uniformly when the punch is being forced into the billet.

The billet is dropped into the die and a centering ring placed on the upper end of billet to guide the punch. A forging for a 6-inch shell is produced at one operation, that is to say the piercing and drawing are done with one stroke of the punch, the piercing causing an upward extension of metal out of the die. The return stroke of the press withdraws the punch and the forging is forced up from the die by means of a hydraulic kicker. The forging is then removed and placed on a gravity carrier system and carried

INTERIOR OF FORGE PLANT SHOWING INSTALLATION OF PRESSES FOR 6 INCH AND 75 MM. FORGINGS

to the other end of the shop to the cooling floor. The punch and dies are cooled by means of water distributed from a perforated pipe ring around the base of the punch. The return water from the presses flows back to an underground tank and is pumped back to the main feed tanks.

### Cooling System

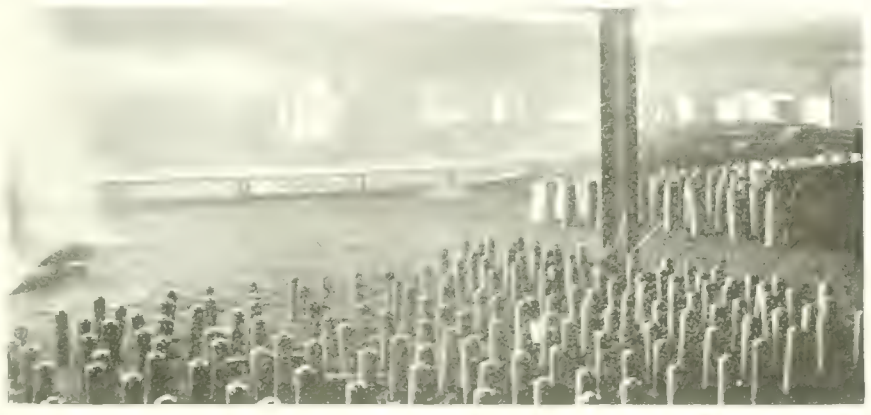
A considerable floor area is devoted to the cooling of forgings, the entire end of the shop being used for this purpose. A large floor area is required because the forgings are not piled but spread around on the floor, end up, which consequently takes up considerable space. During cooling the forgings are laid out in batches according to the heat number, these having already been stamped on the forgings to correspond with the numbers on the billets. The time occupied in cooling and the distance separating each forging during the process varies according to the heat number, precisely as the temperature of the furnaces varies.

The analysis of each batch of forgings is known and is identified by means of the heat number. The cooling must be done slowly or quickly to correct any deficiency or otherwise in the analysis. For slow cooling the forgings are piled close together and protected from draughts by sheet iron. For quick cooling a reverse process is used, that is, the forgings are placed some distance apart and air allowed to circulate freely. Rapid cooling hardens the steel and conversely slow cooling anneals the metal.

### Testing Six-inch Forgings

When each batch of forgings has been cooled, they are stacked up, the piles still being kept distinct according to the heat number. Two or three forgings are selected at random from each pile and then taken over to the machine shop, where two test pieces are cut from the walls of each shell at a point about 4 to 5 inches from the base. The test pieces are milled down and sawn out and then turned up on a lathe to the required form. They are then sent to the Government laboratory to be tested.

Each batch of forgings remains piled until the results of the test are known. If the test is satisfactory the forgings are shipped and if faulty, the batch has to be heat treated. Each forging is also inspected for size and uniformity. In this test the forgings are placed in a mandril, gauged and carefully examined. Any forging that does not conform to the specifications is placed on one side and rectified. The base of each test forging is cut off, split in two and examined for piping or other flaws.

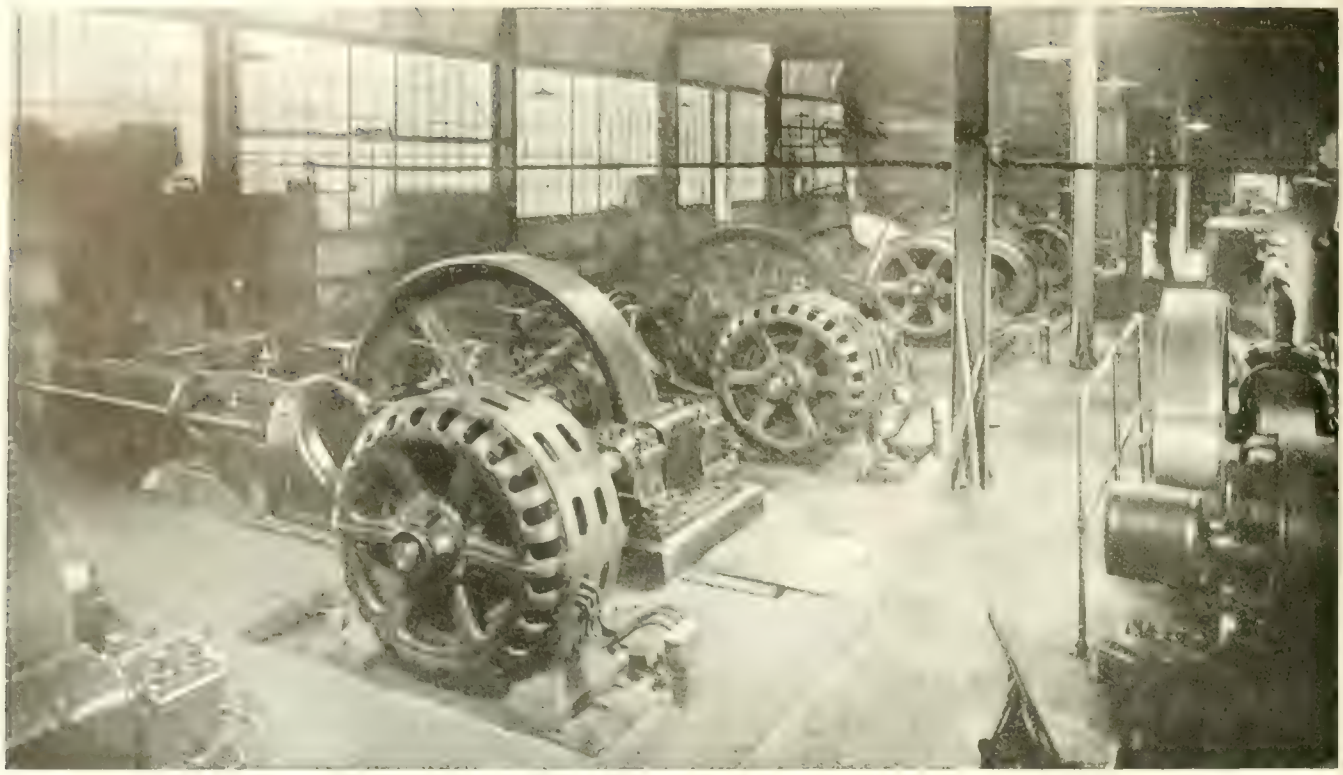


COOLING FLOOR SHOWING 75 MM. FORGING IN THE FOREGROUND AND 6-INCH ON THE RIGHT. GRAVITY CRANE SHOWN IN THE MIDDLE DISTANCE.

### 75 m.m. Billet Plant

The 75 m.m. high explosive shell is a French type of shell which has been adopted by the American Government for the field artillery. It is rather smaller than the 18-pounder, shrapnel being approximately 2 15 16 diameter. The forging operation is similar to that used for the shrapnel shell. The bars from which the billets or blanks are made come to this plant in 10-foot lengths. They weight about 300 pounds and are 3 1 3-inch diameter. They are rolled bars of special steel and carry a heat number which is carefully maintained throughout all operations. The bars are piled after being taken from the cars, each pile containing bars of a uniform analysis; the same procedure being adopted as for the 6-inch billets. From the piles the bars are carried on a conveyor to a table to be nicked preparatory to being broken into short lengths. The nicking is done by an oxy-acetylene blow pipe. By means of this process it has been found that a clean fracture can be obtained without any splinters or damage to the billet. Along the edge of the table at the end are a number of wood blocks set at equal and fixed dis-

HEAT TREATING DEPARTMENT, SHOWING COOLING MACHINE ON [illegible] THE BILLETS ARRIVE IN PILES BEFORE BEING [illegible]



BATTERY OF SIX DEANE PUMPS FOR SUPPLYING POWER FOR HYDRAULIC PRESSES

for the blow pipe so that the operator can cut the nick in the correct position without having to previously mark the bar. The blow pipe is fitted with a flat plate which rests against the wood block when in operation; the oxy-acetylene outfit was supplied by the Carter Welding Co., Toronto. When the nicking operation has been completed, which occupies a very few minutes, the bars are rolled along the table to vertical, motor-driven punching machine or breaker where the bars are broken into short lengths. The breaker, which was supplied by the Hilles & Jones Co., Wilmington, Del., is equipped with a V-shaped tool. The bars are placed in the breaker with the nicked side underneath which, on account of the nick, obviates splintering the billets. This machine is fitted with a stop to regulate the length of the billets, the stop automatically falling down when the punch begins to travel down so to as permit the billet to fall clear. A high rate of production is obtained on this machine. The billets are piled in this department and taken over when required to the piles back of the furnaces. The billets in each pile have a uniform analysis, the heat number having been stamped on each section of the bar after the nicking operation. The billets are 10 inches long and weight 22 lbs.

### 75 m.m. Forging Plant

The furnaces employed for heating the 75 m.m. billets have already been described. They are continuous furnaces, the same type as are used for the 6-inch billets. Three of the nine furnaces are used for the 75 m.m. forgings operation, each furnace having a capacity of 250 billets. The temperature in the furnace is the same as for the 6-inch and the time occupied in heating is about the same, varying according to the demands of the presses. The billets are fed in at the back and drawn at the front end of the furnace. Three presses are used for making the 75 m.m. forgings, two for the drawing and one for the piercing operation, the former being 210-ton presses and the latter a 300-ton press. The capacity of the three presses ranges from 1,400 to 1,800 forgings in twelve hours.

Each press has two sets of punches and dies. The piercing press is equipped with automatic picker for lifting the forgings from the dies and the draw presses have strippers which release the forgings from the dies, allowing them to fall to the ground. The punches and dies are cooled with water and the dies greased after each operation. The forgings, immediately after passing through the piercing operation, are carried to the next presses to be drawn without any intermediate heating. The 75 m.m. forging is practically the same diameter and weight as the billet but is 13½ inches long. The heat number is stamped on the forging as it comes from the drawing press.

### Cooling and Testing 75 m.m. Forgings

The procedure adopted for cooling the

NICKING THE BAR WITH THE OXY-ACETYLENE TORCH

75 m.m. forgings is practically the same as for the 6-inch. That is to say, the analysis of the steel has to be taken into consideration in the time allowed for cooling and arrangement of forgings on the floor during that process. The forgings are carried from the presses to the cooling floors by means of the gravity carrier already mentioned. When the forgings have cooled off they are laid in piles according to the heat number and a few forgings selected for testing purposes. The test pieces are cut out and prepared in the same way as for the 6-inch, and each forging is carefully gauged and examined.

### Machine Shop

The company have a well equipped machine shop for making and repairing punches and dies, which are vanadium steel, and also for effecting repairs required to be done for any equipment in the plant. Adjoining the machine shop is another shop where test pieces are cut out and prepared. In this department is a battery of sixteen-inch Racine hack saw machines used for cutting off the crop ends of the 75 m.m. billets.

### Retreating Plant

Owing to the rigid specifications covering the analysis of the steel used for shells it often happens that some shells are either above or below the limit of carbon content. Forgings rejected on this account can be heat treated and saved from the scrap heap. The company have equipped a special plant for retreating rejects either from their own plant or any other in the district. The plant comprises two batch furnaces and eight specially designed cooling machines for cooling forgings rapidly. The furnaces will hold 85 to 90 6-inch forgings. They are oil fired, the temperature ranging from 1,500 to 1,650 degrees Fahr., according to the condition of the forgings being treated. The forgings are piled on a truck and run into the furnace. At the proper time the trucks are run out at the opposite end and the forgings laid out on the floor or taken to the cooling machines as the case may be. The tracks are laid out so as to occupy a minimum amount of room.

SHEARING 75 MM. BILLETS FROM BAR ON BILLES & JONES BREAKER BAND SAW MACHINE FOR CUTTING METALS

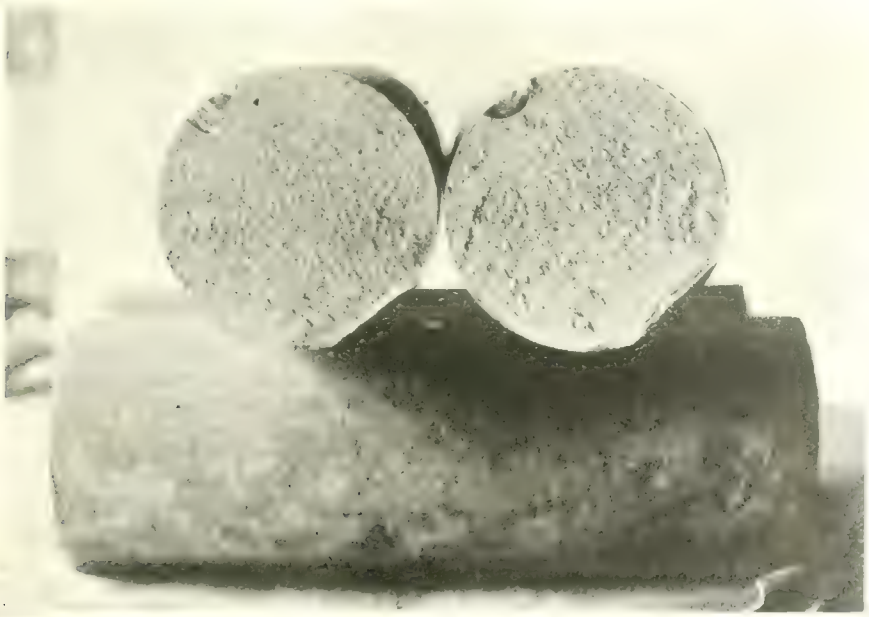
The extreme soft forgings are treated in the air cooling machines after being first heated in the furnace. The cooling machine consists of a cylindrical iron casting for containing the forging. At the open end a perforated pipe is introduced into the bore of the shell while at the back end another pipe delivers air around the base and outside of the forging. By this method the forging is cooled rapidly and consequently hardened. Air is supplied from Roots rotary pressure blower having a capacity of 13,000 cubic feet of air per minute, and operated by a Canadian Westinghouse motor.

Some forgings are annealed in the furnace, being heated for about two hours, and then allowed to cool gradually in the furnace. Some are normalized by being hardened a few degrees, while a common process is to heat the forgings and then lay them out on the floor to cool gradually, the time depending upon results required.

### Hydraulic Plant

The hydraulic plant for operating the presses consists of two large accumulators and six motor-driven pumps. One accumulator has an 18-inch ram and the other a 15-inch ram, both operating at a pressure of 1,500 pounds. Five of the pumps have a capacity of 200 g. p. m. The pumps were supplied by the Deane Steam Pump Co., Holyoke, Mass., and the motors by the Canadian Westinghouse Co., Hamilton. The pumps are all horizontal direct acting units driven through gearing. The motors are 200 h.p. machines, running at 480 r. m. p. and use hydro current at 550 volts, which is reduced from 2,000 volts by transformers. The fan for supplying air to the oil burners is driven by a 28 h.p. Canadian General Electric motor running at 100 r. p. m.

The fan was supplied by the Canadian Blower Co., Kitchener, Ont. The returns from the hydraulic presses pass to an underground tank and are then pumped to another tank above the floor by a centrifugal pump. The latter tank is the supply for the accumulator pumps.



SHELL BILLETS AFTER BREAKING TO LENGTH, SHOWING CLEAN AND SILKY FRACTURE. THE NICK PRODUCED BY THE TORCH IS PLAINLY SHOWN

Aeroplanes for carrying mails are the subject of a call for bids recently issued by the U. S. Post Office Department. The specifications call for five machines, each capable of carrying 300 pounds of mail a distance of not less than 200 miles, nonstop, maximum speed under full load, 100 miles per hour, minimum speed under full load, 45 miles per hour, climbing speed 6,000 feet in 10 minutes, equipped with a 150-horse-power motor.

# 160 Brake Horse Power Semi-Diesel Marine Oil Engine

*The Beardmore semi-Diesel engine is a type of prime mover which has demonstrated its suitability for developing power such as is required for coasting vessels and fishing boats. By operating on the four-stroke cycle, the required power is developed at a moderate speed and the resulting propeller efficiency makes this type of motor of interest to owners of vessels with limited draft. Constructional and operating features are fully dealt with.*

THE advantages of the internal-combustion engine as a means of marine propulsion is undoubtedly the principal reason for its application to the smaller types of vessels, and the development of the modern type of oil engine, together with the rapid increase in power developed per unit, has made it possible to use this type of engine for the propulsion of even the largest vessels. Quite recently this type of engine was universally regarded as being suitable for the development of only relatively small powers, say, 25 brake horse-power to 30 brake horse-power per cylinder, but recent modifications in design and the virtues of rigid simplicity have brought into favor even for powers up to 130 brake horse-power per cylinder.

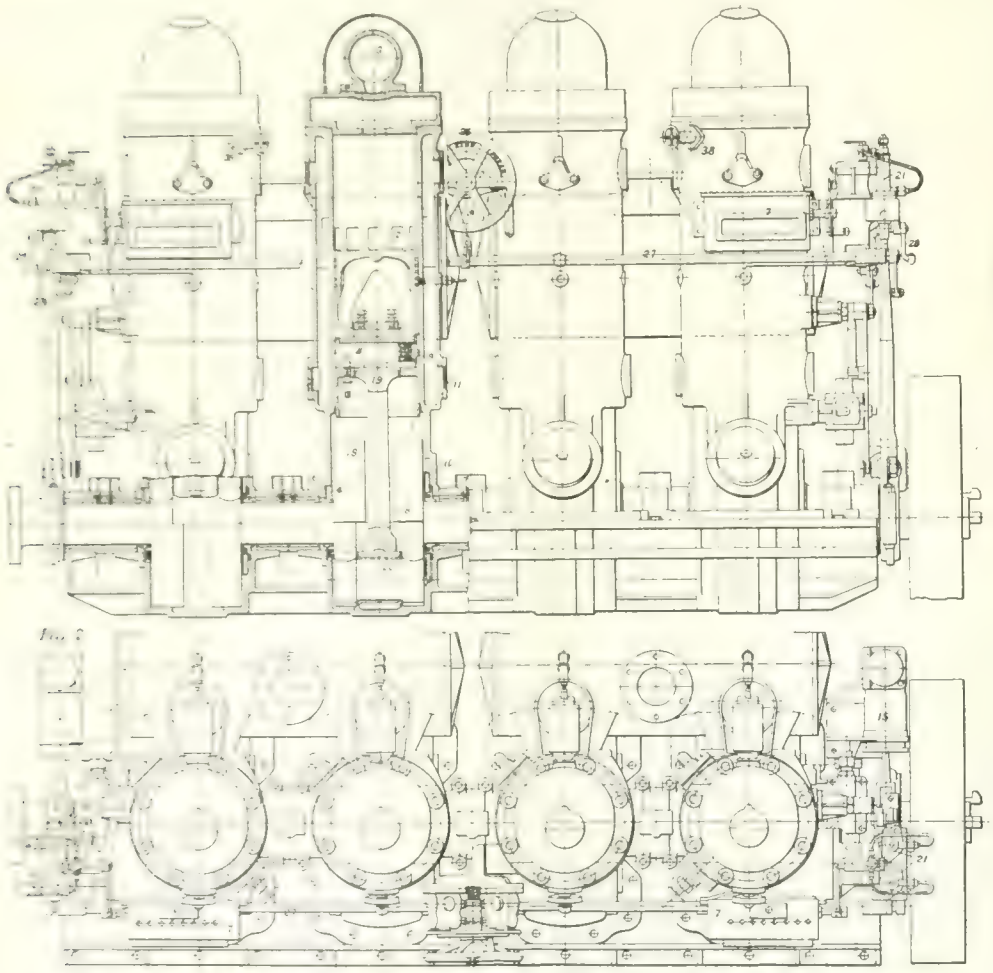
### Field of Application

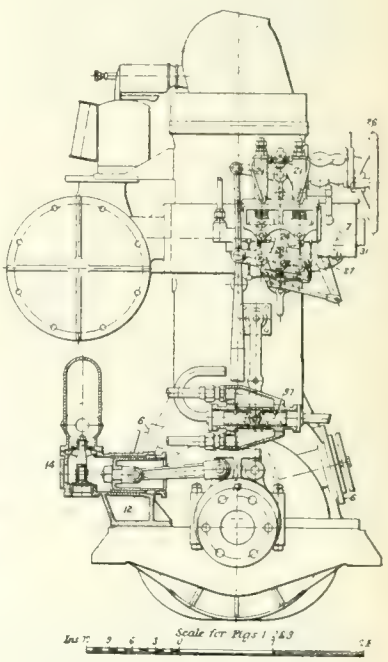
The great majority of marine semi-Diesel engines have points of similarity in the system upon which they work, and practically all are of the two-stroke cycle, utilising the enclosed crank chamber for the compression of scavenging air. The Beardmore engine has been designed essentially to meet the peculiar requirements of marine propulsion, and is the result of much experience with this type of engine installed in yachts, coasters, lighters and fishing vessels.

It is particularly suited to consume fuels ranging from 0.8 to 0.9 specific gravity, but can be adjusted to use either slightly lighter or heavier oils. Working on the two-stroke cycle, it develops 160-brake horse-power while running at 280 r.p.m. This relatively slow speed of revolution is, of course, conducive to high propeller efficiency. As all bearing surfaces are liberal and materials carefully selected an outstanding feature of the engine is its capacity for long and hard service. The engine is directly reversible by means of compressed air, and requires no disconnecting clutch between the engine and propeller, the latter advantage being one that appeals very strongly to marine engineers in general and oil-engine users in particular. Fig. 1 gives sections and elevations of the engine, Fig. 3 details of the main valves, Fig. 4 diagrams from the cylinder and crank chamber, and Figs. 5 to 8 are general arrangements of an installation on board ship.

### Chief Features

In the main engine there are four cylinders, each 11 in. diameter by 15 in stroke, and the cycle of operations may be briefly described as follows, the reference numbers being those shown on the section of one of the cylinders in Fig. 1:—During the upward stroke of the piston air is drawn through non-return valves into the crank chamber 1, to be compressed on the downward stroke and admitted into the cylinder at the correct moment through scavenging air ports located directly opposite to the exhaust ports 2. These ports are covered and uncovered by the piston, on the top of which a deflector is arranged to give to the air blast the direction most suitable for efficient scavenging. While the under side of the piston is performing the functions of a scavenging air pump the upper side compresses the contents of the previously scavenged





ELEVATION PLAN AND END VIEW OF "BEARDMORE" MARINE OIL ENGINE.

cylinder on the upward stroke in preparation for the downward or power stroke.

A separate fuel pump is provided for each cylinder, and once in each revolution of the engine fuel is sprayed directly into the combustion chamber 3, through pulverising nozzles fitted with automatic check valves, and ignition is

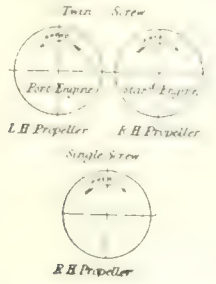


FIG. 2. DIRECTIONS OF ROTATION LOOKING FORWARD

obtained through the fuel impinging on on the heated surface of the combustion chamber.

The combined heat of compression and combustion sustains the temperature necesary for ignition, and consequently no blow lamps are required except for a few minutes before starting the engine. The various operations of working cycle can be clearly understood from an inspection of the indicator diagrams taken from the cylinder and crank chamber and reproduced in Fig. 4, and the sequence and correlation of the operations will be appreciated. These diagrams show the excellent results obtainable by careful design based on extensive experience.

### Scavenging Arrangements

As already stated, scanvenging air is compressed in the enclosed crank chamber, and in order to obtain the necessary quantity of air at a suitable pressure for efficent scavenging the volume of the crank chamber is reduced to a minimum and the whole is made as nearly as possible airtight. The latter condition is difficult to attain where the shaft passes through the walls of the crank chamber, and the method adopted on this engine is interesting. A bronze ring, 4, Fig. 1, is carefully bedded to the body of the shaft close to the crank-web, and is pressed against a machined surface on the inner side of the crank chamber by springs, 5, between the ring and crank-web. The ring revolves with the shaft, and consequently wear is confined to the flat surface and automatically corrected by the springs, which exert sufficient pressure to prevent the ring leaving its face when the air pressure in the crank chamber is below that of the atmosphere.

Since inefficient scavenging is necessarily accompanied by loss of power and waste of fuel, the problem of rendering the crank chamber airtight is of the utmost importance and has received much attention from engineers, but perfect airtightness has not yet been achieved. Channels are therefore provided on this engine between the main-bearing cap and the side of the crank chamber to allow the free escape of any trifling leakage past the ring, and thus to prevent the possibility of interference with the lubrication of the main-bearing bush.

Air is admitted to the crank chamber through grids at the front and back covered by flexible plate valves backed by light springs, and these are mounted on large doors, 6, Fig. 8, the removal of which gives easy access to the crank-pin bushes.

### Lubrication Problem

It will be obvious that with this enclosed type of crank chamber, which is utilised as a scavenging pump, forced lubrication cannot be applied to the crank-pin bearings, because a large quantity of the overflow would be taken up by the air and eventually find its way into the working cylinders, with the attendant result of excessive consumption of lubricant. The question of lubrication, therefore, is a difficult one, but has been solved in this engine in a most satisfactory manner. A forced sight-feed system, with separate plunger pump and oil tube to each point where lubrication must be positive and regular, has been adopted, and by this means the quantity of lubricant supplied to any point is definitely controlled by the attendant, while any interruption of the supply due to a choked tube or faulty valve can be instantly detected and the sight glass shows clearly which point is affected.

Two eight-feed lubricator boxes, 7, Fig. 1, are employed on this four-cylinder engine, and the reciprocating drive is obtained from the fuel-pump actuating gear. The 16 feeds are distributed as follow: three to each cylinder and one to each crank-pin. The cylinder feeds are disposed in such a way as to lubricate the entire working surfaces of the piston and cylinder wall, while one feed also serves to lubricate the gudgeon pin.

The gudgeon pin is hollow, as shown at 8, and is secured in place by a screwed pin, which is split at the point to prevent the possibility of falling out. At the other end of the hollow gudgeon pin is a plunger with a scoop end, 9, which is forced against the cylinder wall by means of a spring and collects oil from the lubricating tube already mentioned. The feed for the crank-pin is carried through the side of the crank chamber and led to the interior of a revolving ring, 10, from which the oil is carried by centrifugal force to its destination. The lubrication of the main bearings is effected by means of siphon tubes—an accepted marine practice.

### Cylinder Construction

The cylinders are cast separately and are extended below the working barrels to form the upper halves of the crank chambers. The cylinder bodies are completely encircled by ample water jackets, and large access doors, 11, are provided to facilitate the removal of any deposit which may be formed therein. The cylinder covers and silencers are also jacketed, and the circulating water is supplied by a reciprocating pump, 12, placed at one end of the bedplate and actuated by an eccentric, 13, on the crankshaft.

The pump body is of cast iron lined with brass and is provided with brass

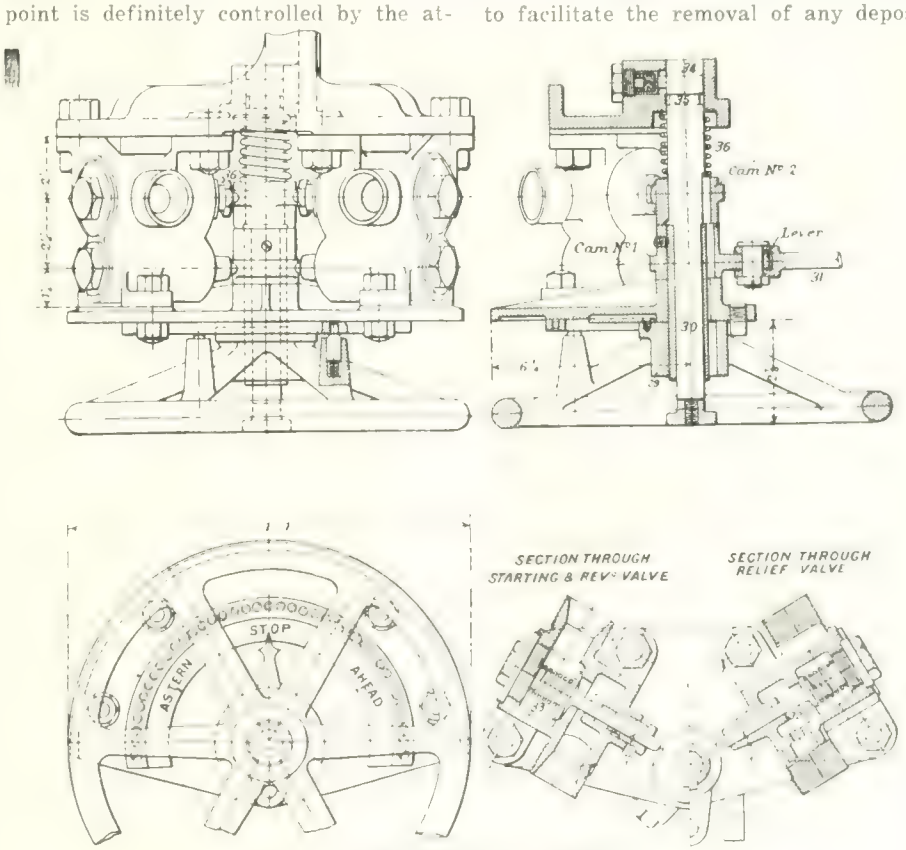

FIG. DETAIL OF MAIN VALVES

seating in the ship, and is provided with 16, Fig. 1, are readily accessible for removal, and when removed the bushes, 17, their outer diameter, can easily be bushes are of Admiralty quality gun-

### Crank Shaft and Rods

Siemens-Martin steel and is machined 1, are secured to the crank-webs, and evenness of turning moment and a desirable freedom from vibration, but also serve to reduce the clearance volume of the crank chamber, and thus increase the scavenging efficiency.

The connecting rods are machined steel forgings fitted with adjustable bearings at top and bottom ends. The top end, 19, of each rod is of special design to allow of easy adjustment, and the bearing surface is of phosphor-bronze. Examination of the gudgeon pin and brush, also piston and piston rings, after the lower end of the connecting rod has been disconnected. The marine-type crank-pin bush, 20, is of Admiralty quality gun-metal, with white metal lining, and is accessible for examination or adjustment through the doors, 6, arranged at the front and the back of the crank chamber.

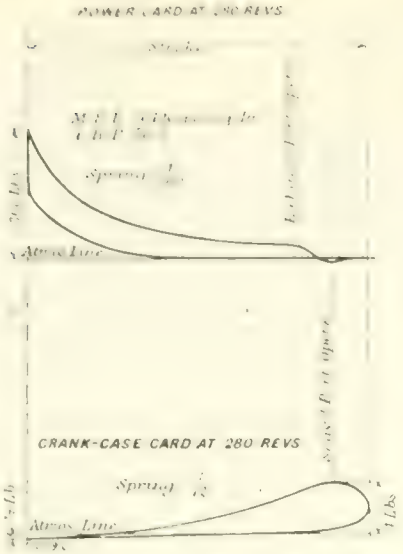

FIG. 4. DIAGRAMS FROM CYLINDER AND CRANK CASE.

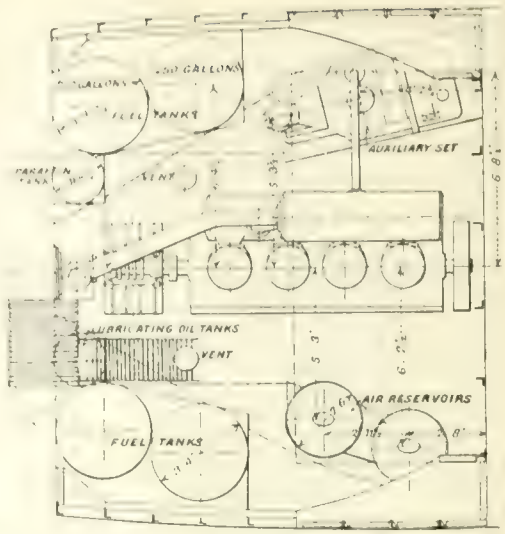

FIG. 5.

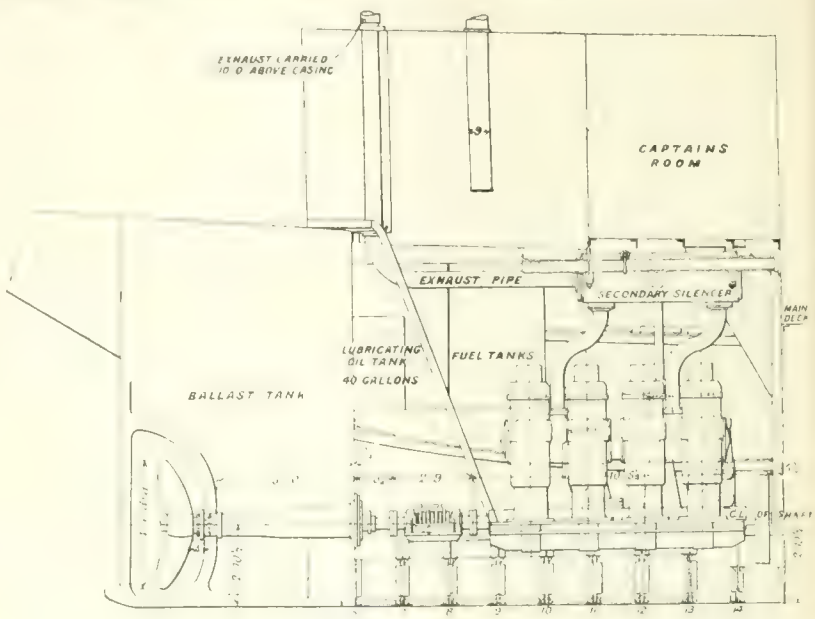

FIG. 8.

### Fuel Pumps

The four fuel pumps, 21, are grouped in pairs at opposite ends of the engine and are operated by the eccentrics, 13, previously mentioned in connection with the water pumps, a horizontal rocking lever, 22, fulcrummed at its centre, being employed to carry the fuel-pump strikers, 23. The stroke of the strikers is, of course, very much in excess of that to be communicated to the fuel-pump of fuel to the combustion chambers is restricted to a very short period. The idle portion of the stroke is utilised for governing purposes, and as the action of one is identical with the others it will be sufficent to describe one. The pump striker is pivoted on the rocking lever and is free to rotate but for the action of a light spring, 24, drawing it towards its guide. On the face of the guide a step is formed which throws the striker off its original course but as this effect is counteracted by the spring already mentioned the engine speed determines whether the striker shall hit or miss the pump plunger.

The tension of the spring can be adjusted to cut out at any engine speed, and when that adjustment has been made the following conditions are fulfilled:—At all engine speeds up to and including a predetermined limit the fuel pump delivers a definite quantity of fuel during a definite fraction of each engine stroke, the quantity delivered being entirely under the control of the attendant on the starting platform, and when the engine speed exceeds the predetermined limit the pump automatically ceases to operate until the normal speed is regained. When it is remembered that all four fuel pumps are alike it will be readily understood that the system of governing is very sensitive and quick in action, and it is worthy of note that the tension of the governor springs can be adjusted either individually or collectively while the engine is running.

The maximum quantity of fuel to be delivered at full power is determined by a screwed collar, 25, Fig. 1, on the lower end of the pump plunger. By turning this collar to right or left the plunger is raised or lowered relatively to the striker and consequently the stroke of the plunger is limited, but this adjustment, of course, is only required when tuning the engine to suit a given quality of fuel and should not be used for any other purpose.

### Engine Control

The ordinary control of the engine speed is effected through a hand wheel, 26, Fig. 1, placed at the centre of the engine. The fuel-pump strikers are mounted on eccentrics in the rocking lever, and these eccentrics are connected by a system of levers and links to a horizontal shaft, 27, running along the front of the engine. Any rotary movement of this shaft is therefore transmitted to the eccentrics, and the strikers are thus raised or lowered collectively according to the direction of movement imparted to the horizontal shaft by the hand wheel. Very fine graduations of

the engine speed are obtainable in this way. A priming handle, 28, is fitted to each fuel pump for charging the pipes before starting, and any pump can be put out of action instantaneously by raising the handle to a horizontal position.

Should it become necessary for a pump to be put out of action permanently the screwed collar already referred to in connection with tuning meets this requirement, and when thus cut out the suction and delivery valves and springs can be removed for examination by simply disconnecting the delivery pipe and screwing out the plug in the top of the pump barrel.

Starting and reversing are effected by means of compressed air and the details of the gear, Fig. 3 show how all the operations of the engine are controlled by a single hand wheel. The hand wheel is mounted on a sleeve, 29, which also carries a lever and cam No. 1, while a central spindle, 30, passing through the sleeve, carries cam No. 2. The lever is connected by a link, 31, Fig. 1 and 3 to the central spindle towards the back, the air-valve spindle drops og the cam and a spring plunger, 32, Fig. 3, entering a groove, 35, in the central spindle, locks it in the new position. The hand wheel can now be used to regulate the speed of the engine without having any effect on the closed air valves, but whenever the wheel is placed in the stop position the central spindle is automatically released and is returned by a spring, 36, to its original position in readiness for a fresh start in either direction.

A start in the astern direction is effected by turning the hand wheel anticlockwise, and thus placing the astern distributing valves in communication with the compressed air reservoirs and opening the ahead distributing valves to the atmosphere. Moving the hand wheel in either direction from the stop position brings the fuel pumps into action, and it is noteworthy that the driver's attention is confined to two simple operations, viz., turning the hand wheel in the proper direction and pushing the

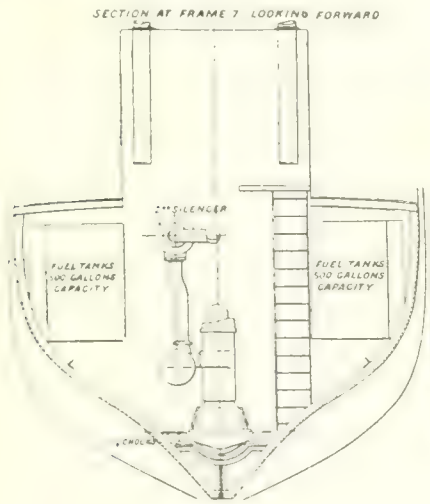

FIG. 6

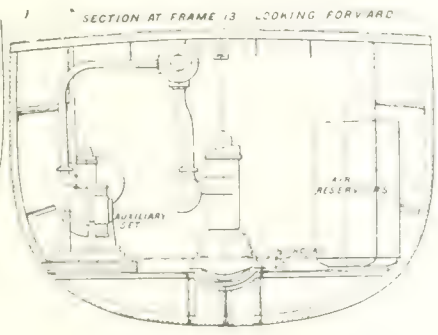

FIG. 7

fuel pump controlling shaft, 27, Figs. 1 and 3, the cam No. 1 opens one of the two relief valves, 32, Fig. 3, and the cam No. 2 opens one of the two high-pressure air valves, 33, Fig. 3. The air valves are directly connected with the compressed-air reservoirs, Figs. 5 and 7 on the one side and with mechanically-operated distributing valves on the other side.

### Manoeuvre Power

It will now be understood that when the hand wheel is turned clockwise the cam No. 2 opens the air valve on the left and admits compressed air to the ahead distributing valves, the cam No. 1 opens the relief valve on the right and places the stern distributing valves in communication with the atmosphere, while the lever brings the fuel pumps into action. The engine then starts on compressed air, but as the fuel pumps operate immediately the engine starts, the air connection can be closed on the completion of one revolution. The latter is the function of the central spindle which carries the cam No. 2. By pushing central spindle when engine has started.

The air-distributing valves, 37, Fig. 1, are actuated by the eccentrics provided for operating the water and fuel pumps, but are brought into operation only when compressed air is admitted to them, and consequently there is no wear and tear of the reversing mechanism while the engine is running. It is an admirable feature of this gear that no part of it is in motion except for a few seconds during each start or reverse of the engine, and it is therefore an easy matter to withdraw valves and other parts for examination or overhaul while the engine is at work.

Two of the engine cylinders are fitted with spring-loaded non-return valves, 38, Fig. 1, through which the air reservoirs can be charged while the engine is running. A sufficient supply can be maintained in this way for all ordinary purposes, but an independent power-driven air compressor is supplied to meet the requirements of excessive manoeuvring and to renew the supply should it be lost from any cause.

Figs. 5 to 8 show a 160 brake horsepower engine installed in a typical British coaster, 75 ft. long between perpendiculars, 18 ft. beam, and 8. ft. 6 in. draught. The auxiliary set consists of an air compressor and general service water pump driven by an independent oil engine, which operates on the same fuel as the main engine. The compressor is capable of charging the air reservoirs to a pressure of 350 lb. per square inch, although the main engine can be started or reversed by air at 100 lb. pressure, and this allows air to be stored in excess of the quantity required for ordinary purposes. In fact the air reservoirs are of such capacity that ordinary manoeuvring requirements can be fully met by one while the other is kept charged for emergencies.

The water pump is capable of performing all the duties of the main bilge and circulating pumps, and is also arranged to deal with water ballast. Fuel is stored in cylindrical tanks having a total capacity of 1,000 gallons, and this quantity gives the vessel an acting radius of 750 nautical miles. The propeller is of cast iron and has three blades of large surface, the propeller shaft is of mild steel encased in a continuous gun-metal liner, and the stern tube is of cast iron fitted with renewable lignum-vitae bearings.

The thrust block is of the most approved marine type, having individually adjustable shoes faced with white metal and a shaft-bearing at each end. The engine in this ship is 10 ft. 5 in. long from the forward face of the flywheel to the aft face of the crankshaft coupling, 5 ft. 4 in. high from centre of shaft to top of combustion chambers, and weighs 145 cwt. with silencers, flywheel, mountings and piping. The weight of the complete installation, including fuel tanks, floor plates, pipes and connections. is 14 tons, and the engine-room bulkheads are 15 ft. apart.

We are indebted to "Engineering" for the data and illustrations contained in this article.

---

THE power from a gallon of gasoline is generally rated in these days by the distance it will propel an automobile. But the same energy, if directed to other and more varied purposes, will milk three hundred cows, bale four tons of hay, mix thirty-five cubic yards of cement, plow three-fifths of an acre of ground, or it will generate enough electricity to light a large farmhouse for thirty hours."

ADVOCATES of all-welded piping systems will be pleased to know that a brewery having a very extensive suction-gas (ammonia) piping system, has just completed remodeling the system, welding the whole to do away with joints. Oxyacetylene was the process used. The progress in this field generally is indicative that the days of flanged headers, receivers, manifolds, etc., as well as piping systems with numerous flanged joints are soon to pass away.

# Advantages of Heat Treatment in Gear Blank Manufacture*

By C. R. Poole**

*... heating and annealing operations connected with the manufacture ... in the machine shop to a considerable degree. ... the advantages of thoroughly annealing the blanks subsequent ... of machining and hardening.*

In this advancement the chemical and metallurgical laboratory have played no small part. During this time, however, the condition of the blanks given the machine shop to be machined, has not received its share of attention in the heat-treating department of many forge shops, and in many cases has been neglected or not considered by the machine shops themselves. This is especially true of shops using only the lower carbon steels.

There are two distinct types of gears, both types having their champions, namely, carbonized and heat-treated. The difference between the two in the matter of steel composition is entirely in the carbon content, the carbon never running higher than twenty-five point in the carbonizing type, while in the heat-treated gears the carbon is seldom lower than thirty-five point. The difference in the final gear is the hardness. ... surface with a soft, tough and ductile core to withstand shock, while the heat-treated gear has a surface that can be touched by a file with a core of the same hardness as the outer surface.

With the exception of several of the higher types of alloy steels, where the percentages of special elements run quite high, which causes a slight air-hardening action, the carbonizing steels are soft enough for machining when air cooled from any temperature, including the finishing temperature at the hammer. This condition has led many drop forge and manufacturing concerns to consider annealing as an unnecessary operation and expense. In many cases the drop forge has only heated to a low temperature, many times just until the piece showed color, to relieve the so-called "hammerstrains." While this has been only a compromise it has been better than no reheating at all, although it has not properly refined the grain which is necessary for good machining conditions.

### Heat Treatment

Before going to the effects of proper annealing temperatures for the most commonly used steels, we will briefly consider the theory of heat-treatment. Heat-treatment, in the broad sense, is the thermal refinement of the structure of steel and covers the four operations, namely: annealing, carbonizing, hardening and drawing or tempering as it is commonly called. All of these operations are based on the fact that in heating a piece of steel the structure undergoes a change at from one to three points on heating and a corresponding number of changes on cooling, these changes being caused by a molecular rearrangement of the carbon and iron. The points are known as "critical points" or "critical ranges" and vary in number according to the composition of the steel. These points on heating are often referred to as "decalescent point" and on cooling as "recalescent point." Carbon exerts the greatest influence on the location of the critical points with nickel and chromium coming next. A straight carbon steel up to thirty-five point carbon has three critical points, from thirty-five to eighty-nine point carbon two critical points are found and over eighty-nine point carbon only one critical temperature is found. Each one per cent. of nickel will lower the critical point twenty degrees Fahr., while each 1 per cent. chromium raises the point ten degrees Fahr. Of the critical points those found on a rising temperature are higher than the corresponding points on a falling temperature. Rising temperatures are always considered in correctly heat-treating a piece of steel. In order to produce the most complete rearrangement of the molecules of carbon and iron and therefore the greatest refinement it is necessary to heat to a temperature slightly in excess of the highest critical point.

Annealing is the heating to a temperature slightly above the highest critical point and cooling slowly either in the air or in the furnace. Annealing is done to accomplish two purposes: (1) to relieve mechanical strains; (2) to soften and produce a maximum refinement of grain.

### Carbonizing

Carbonizing is the operation of imparting to a low carbon steel a shell of high carbon content. This produces what might be termed a "dual" steel, allowing for an outer shell which, when hardened, would withstand wear and a soft ductile core to produce ductility and withstand shock. The operation is carried out by packing the work to be carbonized in boxes with a material rich in carbon and maintaining the box so charged at a temperature in excess of the highest critical point for a length of time to produce the desired depth of carbonized zone. Generally, maintaining at 1650-1700° Fahr. for seven hours will produce a carbonized zone one-thirty-second of an inch deep.

Hardening is the heating to a temperature slightly above the highest critical point and cooling suddenly in some quenching medium such as water or oil. This treatment produces a maximum refinement with the maximum strength.

Drawing is the heating to a temperature below the highest critical point, the temperature used being governed by the results required. This treatment is used to relieve the hardening strains set up by quenching as well as the reducing of the hardness and brittleness of hardened steel.

As the maximum refinement of the grain size of a piece of steel takes place at a temperature at or just slightly above the critical point, increasing temperatures over that point correspondingly increase the grain size. The grain size of a piece of steel is governed by the maximum temperature reached after passing over the highest critical point or by the temperature at which the last mechanical working was given the steel, providing the mechanical work was done at a temperature in excess of the highest critical point.

### The Structure of Annealed Steels

Annealed steels are called pearlitic, pearlite being the name applied to the microstructure of slowly cooled steels. Pearlite is a mechanical mixture consisting of alternate masses of fewite (pure iron) and cementite (cementite being a compound made up of 6 6 per cent. carbon and 93.4 per cent. fewite) with the resultant mixture containing .89 per cent. carbon. Pearlite may be present in two forms, lamellar and granular; with the granular occuring either coarse or fine or elongated with bands of fewite separating the elongated grains of pearlite.

When etched in a weak alcholic solution of picric or nitric acid and examined under the microscope the fewite, untouched by the etching solution appears white, while the pearlite is shown up as a black constituent.

Proper annealing of low carbon steels causes a complete solution or combination to take place between the fewite and pearlite, producing a homogeneous mass of small grains of each, the grains of the pearlite being surrounded by grains of fewite. A steel of this refinement will machine to good advantage, due to the fact that the cutting tool will at all times be in contact with metal of uniform composition and will not be alternately coming in contact with the soft fewite constituent and the harder carbon particles. While the alternate bands of fewite and pearlite are microscopically

sized, it has been found that with a Gleason or Fellows gear cutter that rough cutting can be traced to poorly annealed steels, having either a pronounced banded structure or a coarse granular structure. A study of the microphotographs of several of the widely-used low carbon steels in gear manufacture will show the condition of the structure direct from the drop hammer, the pronounced banded structure of fewite and pearlite and the change produced by thorough annealing.

### Annealing Temperatures

Theoretically annealing should be accomplished at a temperature at just slightly above the critical point. However, in practice, the temperature is raised to a higher point in order to allow for the solution of the carbon and iron to be produced more rapidly as the time required to produce complete solution is reduced as the temperature increases past the critical point. Temperatures, exceeding the critical point by over 100° Fahr., should never be used on account of the enlargement of the grains of pearlite and fewite. Microphotographs of a piece of steel annealed at temperatures increasing by 25° from a point below the critical point to the burning point shows clearly the effects of temperature on the grain size.

For annealing the simpler types of low carbon steels the following temperatures have been found to produce uniform machining conditions on account of producing uniform fine grain pearlite structure.

1.15—.25 carbon straight carbon steel.
Heat to 1650° Fahr. Hold at this temperature until the work is uniformly heated, pull from the furnace and cool in air.

.15—.25carbon 1½ per cent. nickel, ½ per cent. chromium steel.
Heat to 1600° Fahr. Hold at this temperature until the work is uniformly heated, pull from the furnace and cool in air.

.15—.25 carbon 3½ per cent. nickel steel.
Heat to 1575° Fahr. Hold at this temperature until the work is uniformly heated, pull from the furnace and cool in air.

In the annealing of the higher types of chrome nickel steel, with the nickel content running about 3 per cent. and the chromium about 1 per cent. the operation is more difficult, as rapid cooling through the upper critical range produces a hardness due to the slight air hardening properties of steel of this composition. The annealing of this type of steel requires considerable more attention both in the heating and cooling. To produce the best machinability of this steel the following practice will give very satisfactory results:

Heat to a temperature in excess of the critical point about 100° Fahr., holding at this temperature for a considerable time to allow for thorough heating and complete solution of the cementite; cool rapidly, either by pulling from the furnace into air or opening up the furnace doors, to a point at which the forgings show no color in daylight; reheat to a point just in excess of the highest critical point and cool slowly in the furnace. The temperatures, length of heating, time and rate of cooling, are dependent on analysis, size of forging and weight of the load of forgings in the furnace.

Not only will benefits in machining be found by careful annealing of forgings but the subsequent troubles in the hardening plant will be greatly reduced. The advantages in the hardening start with the carbonizing operation, as a steel of uniform and fine grain size will carbonize more uniformly, producing a more even hardness and less chances for soft spots. The holes in the gears will also "close in more uniformly," not causing some gears to require excessive grinding and others with just enough stock. Also all strains will have been removed from the forging, eliminating to a great extent distortion and the resulting noisy gears.

While the steel used for the heat-treated gears is always of a higher carbon content, treatment after forging is necessary for machining, as it would be impossible to get the required production from untreated forgings especially in the alloy steels. The treatment is more delicate, due to the higher percentage of carbon and the natural increase in cementite, together with complex carbides which are present in some of the higher types of alloys. Due to the many analyses of heat-treated gear steel it is impossible to give in this paper specific treatments, but the general procedure is practically the same as for the case hardening, 3 per cent. nickel, 1 per cent. chromium steel given earlier. More time should be given to permit the complex solution to take place and the rate of cooling watched closely, together with the temperature at which the forgings are pulled from the furnace. For a furnace load, weighing 550 lbs., of medium section forgings made from a steel of 50 carbon, 60 manganese, 3 per cent. nickel, 1 per cent. chromium the following treatment gave very good machining conditions on turning operations as well as on the Fellows gear shapers:

Heat to 1330° Fahr., taking 2 hours to heat to the temperature. Hold at the temperature for 1½ hours and allow to cool in furnace to 1170° Fahr., taking about 1 hour to cool. Reheat to 1230° Fahr., consuming ¾ hours to reheat. Hold at 1230° Fahr. for 1¼ hours. Cool slowly in furnace, not faster than 75° for the first hour until 900° Fahr., then cool in air.

In the heat-treated steels poor machining conditions are present, generally due to incomplete solution of cementine rather than bands of free fewite, as in the case of case-hardening steels. This segregation of carbon, as it is sometimes referred to, caused hard spots which, in the forming of the tooth, causes the cutter to ride over the hard metal, producing high spots on the face of the tooth which is as detrimental to satisfactory gear cutting as the drops or low spots produced on the face of the teeth when the pearlite is coarse-grained or in the banded condition.

In the simpler carbonized steels it is not necessary to test the forgings for hardness after the anneal, but with the high percentages of alloys in the carbonizing steels and the heat-treated steels a hardness test is essential. For this test the Brinell hardness tester is far more accurate than the sclerescope test. However, the Brinell test should not be used without the aid of the microscope. To obtain the best results in machining, the microstructure of the metal should be determined and a hardness range set that covers the variations in structure that produce good machining results. By careful control of the heat-treating operation and with the aid of the Brinell hardness tester and the microscope it is possible to continually give forgings that machine uniformly and be soft enough to give desired production. The following gives a few of the hardness numerals on steel used in gear manufacture that produce good machining qualities.

20 carbon, 3 per cent. nickel, 1¼ per cent. chromium—Brinell 156-170.

50 carbon, 3 per cent. nickel, 1 per cent. chromium—Brinell 179-187.

50 carbon chrome vanadium—Brinell 170-179.

## TOOL SCARCITY HAMPERS JAPS

GEORGE SEIDMORE, United States Consul-General at Yokohama, reports that ship carpenters' tools have become so scarce in Japan that the Government is put to great straits to provide a supply. Old tools and second-hand ones are in great demand. Almost any price can be asked for saws and drills. Even the lumbermen are short of axes and circular saws. Before the war Japan looked to England for tools, and they were to be had at reasonable prices and of good quality. Ship riveting drills are especially desired. The British embargoes on these tool supplies threw the Japanese trade to the United States, but of late the demand in this country has caused the export to fall off, and then our embargoes added to the difficulty. Mr. Seidmore says that second-hand tools are now being sold for twice as much as new ones brought three years ago. A similar complaint comes from the Japanese cotton mills. They cannot get their equipment, which formerly came from England, where now these articles cannot be made in quantity enough for home use, and manufacturers are tied up with Government contracts along other lines. The spindles supplied from the United States the Japanese do not like, as they are accustomed to the British makes.

## PRODUCING THE SAME PART IN THREE TYPES OF DIES

By F. Sefton

One of the problems which confronts the die-maker when given a part to manufacture is what type of tool to make so that a low will do the work properly and get out the desired production. There is considerable latitude in this respect and it does not always pay to make the cheapest possible tool, more especially is this true where large production and accurate work is desired.

The purpose of this article is to show three different die constructions which may be used for producing the same piece, together with a brief description of some of the advantages or disadvantages of each type.

The part to be made is shown in the upper left hand corner of Fig. 1, and the die in question is for perforating the hole and blanking out the shape shown. The other two views in this illustration show the appearance of the stock as it comes from the three types of dies and reference to these will be made in connection with description.

The first die to be described, Fig. 2, which is also the simplest in construction, consists of a plain die block A with a stripper plate B. This die block is held in a standard die dish by the beveled surfaces X, the large punch C for cutting out the blank is held in a standard punch holder, while the small punch D is set into the large punch in the manner shown. In setting this punch in, it is simply driven into a hole in the flange of the large punch with a pin E through the shank to prevent it from being pulled out, while the large shoulder takes the thrust of cutting through the stock. This type of punch and die make a cheap construction when they can be made to do the work. In setting this up on the machine it is necessary to be careful and have the die line up exactly with the punch, otherwise the die or punch will be damaged as there is nothing to prevent the two cutting faces from coming in contact.

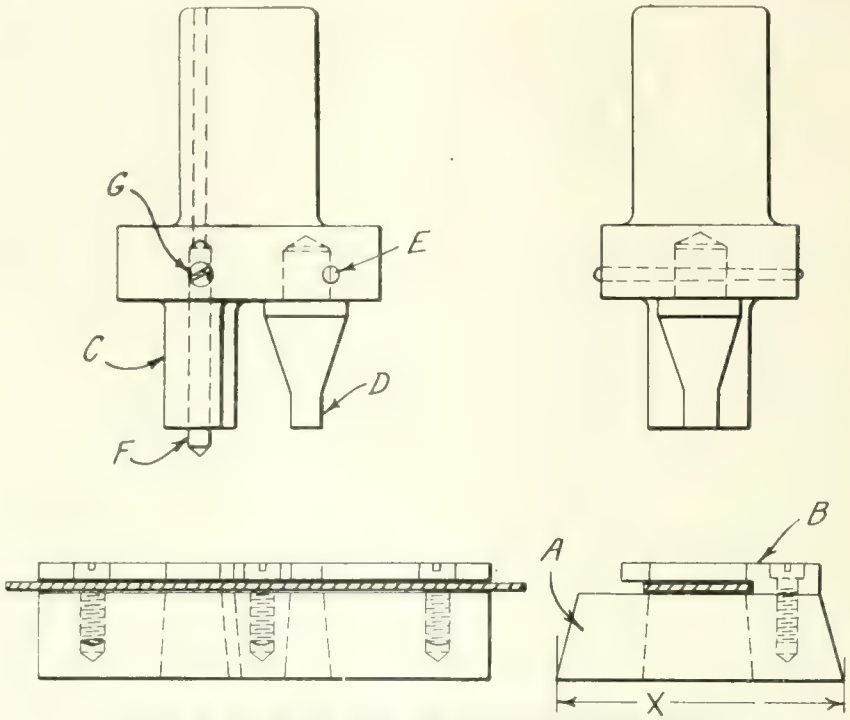

FIG. 2. PLAIN DIE FOR USE IN BEVELED DIE DISH.

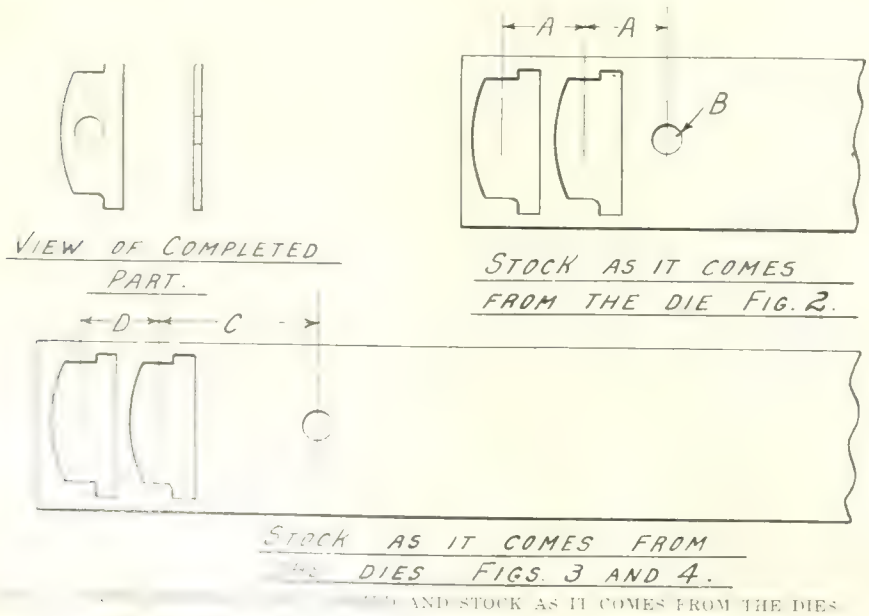
The stripper plate on this tool at B is made open at the front and the stock is fed by hand and in so doing the operator must use care in handling the same to obtain perfect blanks. This die can be improved somewhat in regard to the last feature by putting a couple of pins at the open side to prevent the stock from coming out. When this is done a roll feed may be used which will facilitate the operation of the die and speed up the production.

It will be noticed that in the large punch a pilot pin F is used, the purpose of this being that it will enter the hole previously pierced and locate the stock for the blanking operation. This is held in place by the screw G and as the stock is fed through this die, it will appear as shown in the upper right hand corner of Fig. 1, and the distance A is equal to the distance necessary to make one blank. When the stock enters the die the first time the punch comes down it



AND STOCK AS IT COMES FROM THE DIES

simply perforates the hole B and as the punch comes up the stock is fed forward equal to the distance A again. When the punch comes down it of course perforates another hole and blanks one part; this is then continued successively for the entire length of the stock.

In the lower view of Fig. 1 it will be noticed that the distance between the hole and the first blank C is equal to twice the blanking width D. The object of this is to spread the holes in the die further apart and make it stronger as there will thus be more metal between the holes. This has been done in the remaining two dies to be described, and this view therefore represents the stock as it will come from them.

The tool shown in Fig. 3 consists of the punch holder A, a large punch B, a small punch C, and guide pin D. There is also a die E held on the die plate F and a stripper plate G, in addition to this finger stops and an automatic stop for convenience when feeding the stock are shown. When using this die the stock is fed through the stripper plate in the manner shown, the stripper plate having been cut out so as to hold it from getting out of line sideways. In handling the stock it is first fed until the end comes against the finger stop H and the first hole is pierced. It is next fed until the end comes against the finger stop I and the second hole is pierced, following this it is again fed until it comes against the automatic stop J. At this time a hole is pierced and the first blank is cut out of the stock. This die then operates automatically by using a roll or ratchet feed for the stock. The operation of the automatic stop on the die will be described in connection with the next tool as it is part of the die construction and is made slightly different in various tools depending on the nature of the work.

This die is rugged in construction and is a good producing die, being more economical with the stock than the one shown in Fig. 2, although somewhat more expensive to make. One difficulty met with in punch press work is the necessity for keeping the ram tight or free from side play, for unless this is done the punch will not come down in line with the die, also irregularities in stock will throw the punch out of line with the die, thus causing the same to become chipped. To overcome this difficulty a punch and die are often made with posts or guide rods as shown in Fig. 4. This die is considered first-class construction and contains all of the features of that shown in Fig. 3, with the addition of the guide rods and a die bushing for piercing the small hole.

The parts of this tool consist of a punch holder A, also a die holder B, two guide rods C hold the punch in line with the die, and these rods are provided with oil grooves. The punch holder and the die holder have a slot cut through them at D and E and the large punch F and the die G respectively are fitted into these slots; they are then held securely in place by screws and dowels, thus insuring that the location will be permanent on the holders. The small piercing punch H is driven in the large punch F, and this has a head on it at X so the same will not pull out should it get stuck in the stock.

The pilot pin I completes the punch construction. The die has a bushing J in it, this being ground in place when the face of the die is ground, and it may be removed and replaced should it become damaged as this small hole is considered the weakest part of the die. Two finger stops K and L are provided with this die, and these are held in place by the springs M, the springs in turn being held to the die by means of screws. The automatic stop N, with the tripping screw P and a post for holding the same Q complete the construction of this tool with the exception of a pivot pin R upon which the automatic stop swings and a spring S for operating the automatic stop.

The stock in this instance as in the preceding die is first fed against the finger stop K; this stop is pushed in by the finger of the operator, or better still by a suitable rod in the hand of the operator and the first [illegible]

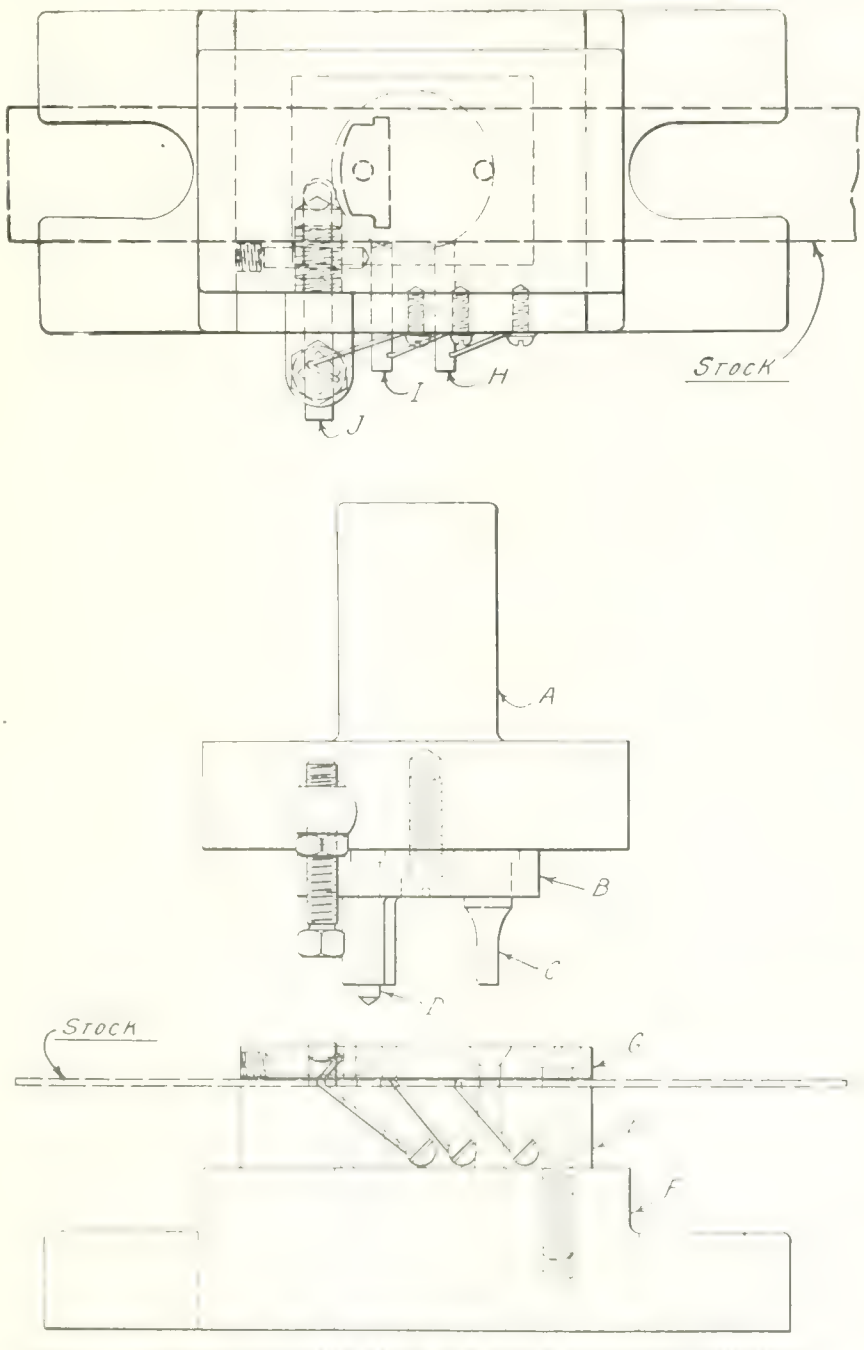


FIG. [illegible] AUTOMATIC DIE WITH FLAT DIE BLOCK AND PUNCH HOLDER

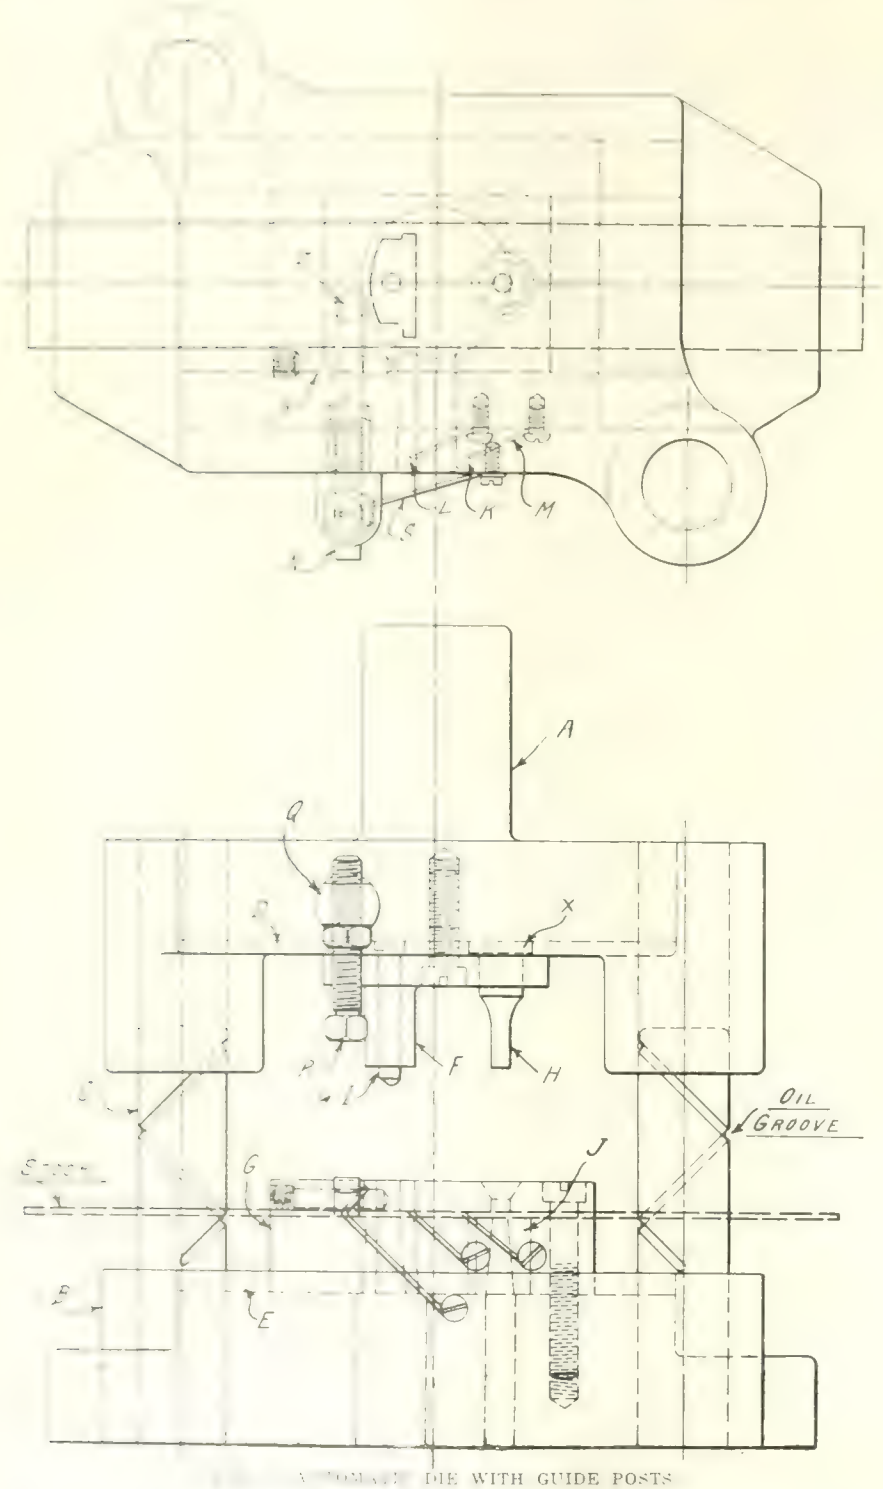
The operator then releases the stop and pushes the finger stop L in and pierces the second hole; he then releases the finger stop and the stock is fed against the automatic stop, where another hole is perforated and the first blank is cut. When, by throwing in the clutch on the press, this tool operates automatically as the automatic stop will drop into each hole in the stock made by the blank successively, thus locating the stock in the

through the perforated holes. The strip-

so that the punch goes up the automatic stop rests on top of the stock. When the automatic feed pushes the stock along, the stop drops into the hole left by the last blank and of course when the end of the hole comes against the stop the stock is thereby located so



AUTOMATIC DIE WITH GUIDE POSTS

In regard to the operation of the

the stud R the rounded end Z tips up out of the hole in the stop, when the

when the punch comes down the pilot pin I will enter a hole previously pierced. This operation is repeated automatically for the length of the stock, thus requiring little attention from the operator. The automatic stop shown in Fig. 4 is also operated in the same manner.

## MUST INCREASE EXPORTS

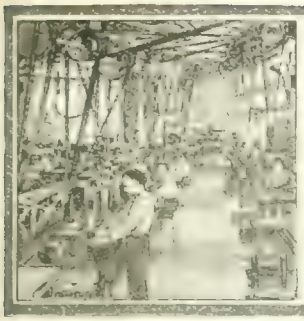
IN the face of the United States' enormous foreign trade credit balance it is evident that, owing to the inability of European Allies to liquidate their indebtedness for some years to come, the United States is facing a situation in which it will be compelled to increase exports to South American and non-belligerent countries, if the resources of the country are to be saved from excessive strain. Unless the situation is improved within the next three or four years, all the surplus of gold accumulated during the first three years of the war will be exhausted and the basis for the large credit operations in Europe seriously weakened.

This is the gist of a report by the National Foreign Trade Council. "So long as the war continues," reads the report, "the shipments to the European Allies and to Canada must be at least maintained at their present volume, and no increased imports of merchandise from Europe can be expected in payments. Such gold shipments as can be made will be a drop in the bucket (the United States having already more than 1-3 of the total visible gold supply of the world) and American securities which can be sent back from Europe to the United States are daily becoming scarcer. Hence, the conclusion is inevitable that the United States must from necessity export yearly on credit, pure and simple, merchandise to the value of at least $4,000,000,000, and this represents nearly two-thirds of the total exports."

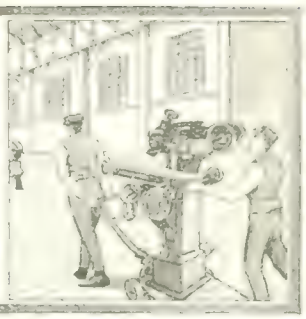
A clear idea of the situation is apparent from the following distribution of our imports and exports for the past calendar year, as regards the Allies and the South American and non-belligerent countries, leaving out, however, the European neutral and enemy countries (last three figures omitted):

| | Imports into U.S. From | Exports from U.S. To |
|---|---|---|
| Europe (Allies) | $ 445,415 | $3,732,836 |
| Canada | 413,674 | 829,972 |
| British and French Oceania | 36,128 | 78,563 |
| British Africa | 40,951 | 39,023 |
| Total | $ 936,288 | $4,680,394 |
| Peru-ma | 7,484 | 28,140 |
| Africa (Non-British) | 32,112 | 12,441 |
| Asia | 758,237 | 431,149 |
| Mexico and Cent. America | 161,575 | 135,177 |
| West Indies | 280,990 | 255,591 |
| South America | 598,818 | 312,420 |
| Philippines | 62,986 | 38,148 |
| Total | $1,894,118 | $1,184,926 |
| | $2,837,810 | $5,893,460 |

It is evident that the United States looks and must continue to look to the second group of countries, above referred to, as the only possible sources of supply for certain raw products absolutely needed for the manufacture of material which must be sent to Canada and to Europe, and food products must be imported on an enormous scale to take the place of those which must be sent out of the country.



# DEVELOPMENTS IN SHOP EQUIPMENT



*Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

## CUTTING-OFF AND FACING MACHINE

The achievement of shell-making during the past three years has been due very largely to the success that has been attained through the adoption of the single purpose machine. Without this particular type of equipment it is doubtful if anything like present performance would have been possible. A design that has not been generally known to the trade, but one that has given exceptional satisfaction in the plant where it has been extensively used, is shown in the accompanying cut. This line of equipment, which covers a range of several designs for various operations, has many interesting features in its construction. The illustration herewith shows the type used for cutting-off and facing; either operation being performed by simply changing the tool post on the cross slide rest. These machines are fitted with a self-contained counter-shaft, the supports being firmly secured to the rear of the machine bed. From this counter-shaft to the main spindle is fitted a short length of chain belt, giving a direct but positive drive to the main spindle. This method of transmitting the power gives an exceptionally powerful drive, one that will stand up to any cut that can be placed upon the tool or the machine.

CUTTING OFF AND FACING MACHINE

The protection of the workman is amply provided for by the use of a suitable guard. Starting and stopping of the machine is obtained by the movement of a handle located just in front of the chain guard. Power feed is obtained by means of a belt connecting the main spindle with the feed shaft that is located in the front of the machine, the cross feed being derived by suitable bevel gearing. Contained in the main spindle is the pneumatic chuck for holding the work, the air being controlled by means of the small handle situated immediately above the main front bearing.

When used for cutting off the open end the machine is fitted with a special bracket extending out from the right hand end; this bracket carries the gaging rod that is operated by the toggle levers shown. This rod can be accurately adjusted to suit the length desired. Special provision is made for the automatic ejection of the shell after the operation has been completed and the air released. These machines are being manufactured by L. A. Desy, Montreal, P. Q.

## ANGLE BENDING MACHINES

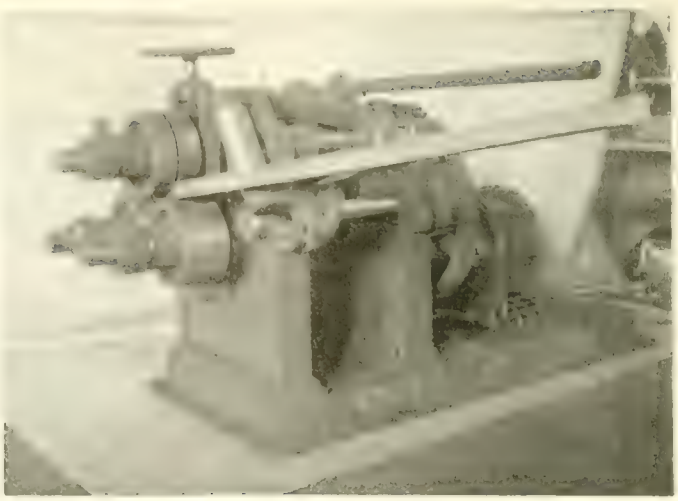
THE accompanying illustrations show several types of power bending machines developed by Kane & Roach, Syracuse, N.Y., for the bending of angles and other structural shapes.

In working out the design of these machines, the bending rolls were placed as close to the floor as possible in order to facilitate the placing of heavy work in the machine. These machines may be equipped for either individual motor or belt drive with reversing pulleys as shown in the illustrations. In cases where belt drive is employed the shifters are so constructed that the operator of the machine can manipulate either shifter to provide for running the machine forward or back, as required. In handling certain classes of work it is necessary to reverse the machine several times to provide for running the work back and forth, and in such cases a conveniently located operating lever is particularly important. It will be noticed that the bending rolls are almost in contact with each other, which results in several desirable features. In the first place, having the rolls close together practically avoids the flat or straight spot at either end of a piece that is being bent, this not only saving time in bending the ends of the work to the required curvature, but also saving material through avoiding the necessity of cropping off the extreme ends of the work which can not be bent to the desired form.

BENDING MACHINES FOR LIGHT ANGLES

Another advantage of having the rolls close together is that the material can be started into the roll to be bent without having to start the bend by hand. This is the means of making a very important reduction in the cost of bending work. A sliding gag under the adjusting screw provides for holding down the top roll, and this gag can be slid out from under

[illegible] ANGLE BENDING MACHINE



MOTOR DRIVEN ANGLE BENDING MACHINE SHOWING ANGLE IN ROLLS

to put work in the machine or take it out after a bend has been completed. With this arrangement the screw adjustment does not have to be altered. When one piece has been removed and another piece has been put into position on the lower rolls the upper roll is dropped into place and the gag slid back under the adjusting screw, after which the machine is ready to continue its operation.

Side rolls are provided at each side of the bending rolls, and these may be swiveled to any angle according to the radius of the curve to which work is being bent. These side rolls can also be adjusted in or out to meet the requirements of different classes of work. They effectually prevent side twisting or buckling of the work during the bending operation and enable the piece to come out perfectly true. The rolls are made of high carbon steel, and the outside sections slide in or out to provide for handling any width of work that comes within the capacity of the machine. The shafts carrying these rolls are exceedingly heavy, and all the front bearings that carry the roller shafts are bushed with bronze. The driving gears are made of steel with cut teeth. With the exception of differences in size the design of all three of these machines is the same. Each machine is provided with a scale and pointer to show just where to set the rolls for bending work to any desired radius of curvature, which is an important feature in simplifying the setting of the machine for any given job.

All three rolls are positively driven by means of gears, thus avoiding any slip.

On the No. 14 angle bending machine light angles up to 2½ in. x 2½ in. x ¼ in. can be bent. To provide for bending larger angles, the manufacturers have brought out a heavy-duty machine that is built in three sizes. The No. 22 machines handles angle irons up to 3 in. x 3 in. x ⅜ in.; the No. 23 machine handles work up to 4 in. x 4 in. x ½ in.; and the No. 26 machine handles work up to 6 in. x 6 in. x ⅝ in. In addition to bending angles, these machines can be employed for bending equivalent sizes of I-beams, channels, T-irons, rounds, squares, tubular stock, flat stock, and other shapes by simply making "filling in" collars or rolls to suit any particular kind of work. It is also possible to bend either one angle or two angles at a time, according to the quantity of work which is being handled.

EDGES FROM THE SHELL BASE.

## SHELL GAS CHECK PEINING MACHINE

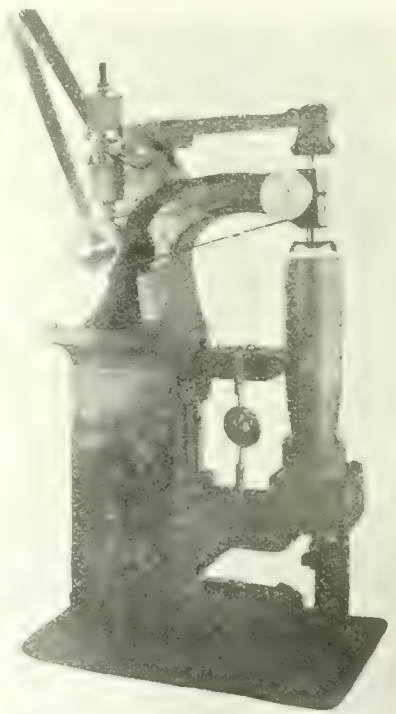
THE accompanying illustrations show two views of a new machine, manufactured by the High-Speed Hammer Co., Rochester, N.Y., which is especially adapted for caulking or peining the gas checks in the base of the 155 mm. shell

After placing a shell in the machine the combination burring and crimping tool as shown in photo No. 1 is applied. One or two revolutions of this tool (which is revolved by means of handles) under slight pressure will remove any burrs or sharp edges from the angular groove in base of the shell. If these are not removed there is danger that the gas check may be cut through during the peining operation.

The copper gas check is placed in position and the crimping operation is accomplished by a half turn. The burring and crimping tool is now removed.

With the gas check in place the lead wire gasket is inserted and the machine as shown in photo No. 2 is started by foot treadle. Controlled elastic blows, at the rate of 900 per minute are struck, and the pein slowly revolves, thus caulking the lead firmly into the angular groove, and also caulking the lead to conform to angle required.

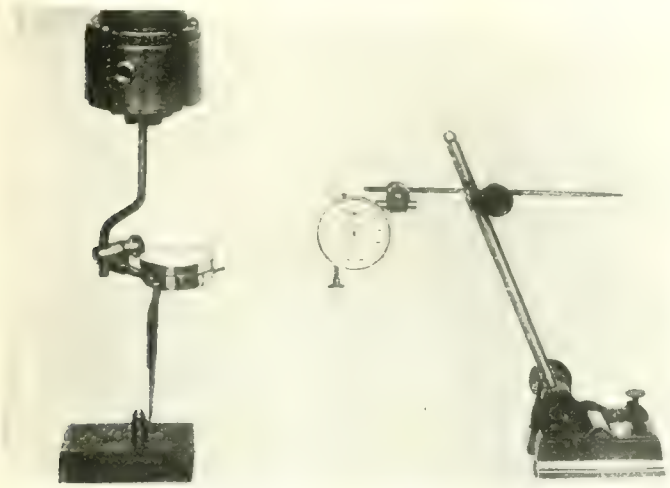
The operation is completed in less than 30 seconds.



[illegible] SHELL IN POSITION READY FOR CAULKING.

## DIAL INDICATOR

A dial indicator with a wide range of adaptability has recently been developed by B. L. Gates, 125 South Wells St., Chicago. The accompanying illustrations show some of the uses of this indicator



SOME USES OF A DIAL INDICATOR

and illustrate the way in which it may be attached to the ordinary tools and instruments of everyday use.

The connections are universal and can be placed in any position. The bent connecting rod is advantageous, making heavy and cumbersome connections unnecessary.

In measuring the plunger is brought down until the hand indicates .003 or more, it being easier to calculate the measurements from a reading than to bring the initial reading to zero.

The indicator measures by 1,000ths of an inch to .130, and by attaching it to a height gauge or by the use of blocks any distance can be measured. The dial indicator may be used on vertical milling machines, horizontal or vertical boring machines and is always in such a position that the dial can be seen. The workman is not obliged to walk around a machine to true up a job.

An extension is provided for machine work where the job or some part of it is to be made central. This extension will enter a very small hole and will reach the depth of 3 inches.

## METAL CUTTING BAND SAW

THE band saw machine illustrated herewith is a recent product of the Napier Saw Works, Springfield, Mass., and is adapted to the rapid cutting of soft steel, tool steel and soft metals of all kinds.

A gravity feed operated by the balanced weight of the tilting head is used. A spring at the back of the machine is in such a position and of such tension that the feeding weight is constant from the start to the finish of any cut which can be made on the machine.

The base is of cabinet type with lubricating tank enclosed. All bearings are extra large. The bearings in the clutch pulley, and in the driving and idle wheels, which carry the tension of the saw, are heavy and rigid.

The cutting band is lower than the returning band thus making it possible to cut off any length required. The cutting band is supported by truss arms, each carrying a pair of guides specially designed.

By means of the roll guides the band saw is directed so that its travel between the truss arms is absolutely vertical, thus assuring straight cutting. These guides once set are in perfect adjustment for any saw which may be placed on the machine. This is a feature not found on any other machine.

A rotary pump of simple design provides amply cutting compound for the saw. The teeth of the band saw are downward in the cut which insures that the cutting compound flows at once to the point of the saw tooth where it is needed.

The manufacturers recommend a saw speed of 120 lin. ft. per min. for soft steel, 100 lin. ft. per min. for tool steel and 150 lin. ft. per min. for soft metals. A one-horsepower motor is required for the operation of the saw which occupies a floor space 4 ft. x 6 ft.

## STEEL TRADE MEETS DEMAND

REMARKABLE expansion in the steel output of Great Britain has been an outstanding feature of the war. The production has grown so that now it is 50 per cent. greater than it was before the war started. The following comment from the London *Iron and Coal Trades Review* explains this unusual growth:

"The work of extending existing plants and of putting down steel works has proceeded very satisfactorily during 1917, notwithstanding the obvious difficulties occasioned by the state of war. Several entirely new undertakings are now in active, though not yet in the fullest, operation, and a number of others will be ready early this year. The output of acid and basic steel (excluding steel castings and crucible steel) in the United Kingdom in 1914 was not more than about 7,800,000 tons. In 1916, including steel castings, it had been brought up to about 9,200,000 tons. During the year just ended, taking account of the extensions in hand, it has been increased to 10,500,000 or 11,000,000 tons. This is a remarkable achievement, but when all the new plants are completed the annual production should not be less than about 12,000,000 tons. Government control during 1917 has not only been maintained, but intensified, for practically the whole production has been required, directly and indirectly, for purposes of the war. All engaged have worked with felicitous harmony and goodwill, anxious only to forward the great cause in which they are privileged to play so important and, indeed, vital, part."

VOL. XIX. MAY 9, 1918 No. 19

### WAR TIME PERSPECTIVE

THE relative importance of different lines of activity becomes more apparent as conditions become more serious. Human endeavor must be directed in whatever direction is most necessary.

The activities of the Food Controller indicate that fighting is the prime necessity, with food a good second. The food, however, is being watched in view of military requirements and not because of philanthropic considerations for the general public.

Confirmatory evidence of this feature of national policy is an agreement just arrived at by American steel makers regarding the disposal of commercial steel as distinct from straight war work. Priority is given to steel involving oil development and transportation, followed by steel involved in agriculture.

These two considerations indicate the true perspective which is gradually becoming more apparent. Oil development is necessary for fuel, because without fuel there would be very restricted transportation, as well as much less efficient operation of naval forces. Smoke barrage at sea is a development rendered possible by the close control of combustion obtainable with oil fuel when burned under boilers. When used in internal combustion engines, oil fuel becomes the most efficient method of power generation from heat.

Recognition of the demands of agriculture is evidenced by the second consideration. Tractor importation and manufacture should be pushed to the limit for the immediate future. Tractors take time to make, material takes time to get, crops take time to grow; a tractor on the farm this season will be worth ten in the maker's catalog next spring.

Apart altogether from the political aspect, the expediency of remitting the duty on tractor material is evident to all. The relatively small amount of revenue lost thereby to the country would be a small price to pay in order to insure the possible maximum production, this season and next. The partial disintegration of shop organizations manufacturing plans in this case have a direct detrimental affect on the trade balance, and in addition to military reasons, future economic considerations render the development of the tractor and allied industries most essential.

Importation is necessary for the present, but manufacture should be kept in a healthy state to assure independence in the future.

### GRAFT, TREACHERY AND INEFFICIENCY

THE occurrence of charges, baseless or otherwise, seems at some time or another to be part of the lot of every warring nation.

Whether, if the events of the past four years were to happen again, and taking into account the changed condition of the national mind, such incidents would reoccur, is not of present importance. The point is that no matter how high the ideals and good the intentions of a belligerent in the national sense there is always opportunity for graft if some one wishes to practise it.

The most dangerous form of graft is that which originates from enemy sources. It is not so concerned with actual money losses which it can cause the Allies but more with retardation of production and inefficient material. It seems as if the distorted Hun intellect was designed to fit the requirements of predestined iniquity and specialize in the devious ways of the devil.

When gas masks and aeroplanes are tampered with not only is danger and death brought to the forces but untold anguish caused to non-combatant friends and relatives as well as anxiety to officials.

Charges of a serious nature have been made in Washington by Gutzom Borglum and an investigation ordered by President Wilson. Pro-German influence is hinted at and a general cleaning up of the whole aircraft position seems imminent. The day when military considerations rendered secrecy in this respect vital would seem to be approaching an end. If production is good and at a rate sufficient to influence results soon, the German nation which is now at the extreme peak of production will be more likely to be discouraged if it were made aware of actual facts.

On the other hand, if production has been seriously handicapped an exposure of the methods would strengthen home public opinion and put many additional individuals on the qui vive for what is nothing less than treachery.

Inefficiency is not such a vital factor as the two foregoing as its effects are closely circumscribed by inspection methods. Any weakness in this respect is more likely to react on the producer as witnessed by a recent incident where a plant was closed down because of the misdirected energies of a subordinate who wished to reduce the cost of machining by performing an additional operation on the shell blanks.

Had the matter been discussed with government officials first, a clear understanding would have been arrived at, but the fact that they and the firm also were unaware was sufficient grounds for the authorities to refuse to run the risk of further digression from specification, however unintentional and harmless, etc.

### INCREASE PRODUCTION AND REDUCE CONSUMPTION

EVIDENCE regarding the ever-increasing necessity for greater effort and denial on the part of every subject of the allied nations continues to accumulate. The calling to the colors unconditionally of men between 20 and 23 years of age and the registration of men 19 years old has impressed both the public and manufacturers with the importance of man-power.

Government distribution of tractors has given further impetus to the greater production campaign while the activities of food and fuel controllers serve to remind us that the increased production is for others, not for us.

The cumulative effects of the war are destined to become more apparent this year than last. The loss of 250,000 effectives from the combatant strength of the British army means that some other strata of national life and activity must suffer so that the effects of the loss may be counteracted.

Increased use of mechanical appliances in the army and the further drain on British manhood by the fifty-year limit are two ominous factors whose influence on Canadian industrial activity may soon become apparent.

Every ton of steel produced in the United States which can be utilized by the Government and its Allies will be made available for their use. Following a meeting in New York recently between the Director of Steel Supplies and about fifty steel manufacturers, Judge Gary, as president of the American Iron and Steel Institute, requested that each manufacturer sign a pledge to do his utmost.

Authorities state that at the beginning of April the general outlook was that there would be an ample supply of steel for war purposes with a sufficiency for commercial use, but developments since, both military and otherwise, have reversed such a prospect.

# MUST LIKE YOUR WORK TO GET BEST RESULTS

**Enoch Cronk Has Been With The A. R. Williams In Various Capacities For Almost 36 Years**

IF a person were to ask Enoch Cronk point blank to name his "official capacity" with the A. R. Williams Machinery Co., we doubt if he could do it in one or two words. The chances are he would have to use from a half dozen up. He's not a highly trained mechanical expert, never served an apprenticeship in a machine shop, never studied law nor did he ever have a special course

ENOCH CRONK

in the fine but delicate art of repossessing machinery when the ownership of it becomes a disputed point.

But Mr. Cronk knows a good deal about machinery, has a pretty clear idea of what a man requires in the way of equipment for a stated performance, knows absolutely and without apology enough fine points in law to hang up his shingle, and when it comes to the matter of leading a sawmill plant back to the company yards, and still live on good terms with the people who fail to observe agreements—well, Enoch Cronk is right in his element.

Mr. Cronk didn't exactly tell his story for publication, but it's going to be published. In fact, during a conversation CANADIAN MACHINERY had with him he kept up a barrage fire of warning that he wasn't speaking for print. However, we'll fight that out with him later on.

### Came From the Farm

"I don't know the machinery trade," said Mr. Cronk, "that is I never served an apprenticeship at it. But I have been around here for thirty-four years with the A. R. Williams Co. In that time I've been in charge of the supply department, shipping department, and acted as salesman, looked after collections and the taking back of plants when payments have dropped."

In answer to a query as to what he did before coming to Toronto, Mr. Cronk remarked: "I was a farmer, a plain, hand-working and hard-luck farmer. I had a place in Prince Edward County. I was burned out once, and not long after the same thing happened again. That settled it for me. A few days after I told my wife 'I've ploughed my last furrow.' I meant it and I lived up to it. I came to Toronto and got a place with the late Mr. Williams. I told him then I would try it for a month and see if I'd stay on. I remember quite well that I told him if I didn't love my labor I would not stay. No man can do his best if he doesn't like what he's working at. Well," continued Mr. Cronk, "that was just about thirty-six years ago, so you see I stayed a little longer than the month I started on. I've been here ever since. I like it and I'm going to stay as long as my working days last."

### Lots of Hard Work, Too

Mr. Cronk returned a few weeks ago from taking out a sawmill plant near Monteith, in Northern Ontario. Rather a strenuous piece of work for a man 76 years of age. He doesn't look it. The CANADIAN MACHINERY man guessed him at 65, but Mr. Cronk was willing to have us add ten and a little more. The mill up north went through the fire. The Monteith Pulp & Paper Co. took up property a little piece off and started to develop water power, flooding the old mill property. "It was only about ten feet to the Driftwood river," stated Mr. Cronk, "but there was a bad bank and about fourteen feet up on the other side. The river was about thirty feet over, deep and fast. And remember that in a place like that we haven't got all the equipment under the sun to work with. A jack screw, stumping machine, some good horses, that's the outfit. We had a hard job getting a crossing built for the river. We had to have tree trunks that would be of such size as to take the load evenly or else we'd have it dumped in the river. We had a boiler and engine and the mill machinery—I suppose five or six tons in all. Snow? They wanted us to take the regular road for it. I didn't. If I had we'd been there yet. We dug out a new road where the snow hadn't been over four feet. On that old road there were places where it was a good twenty feet deep. Well, we finally did the trick, put it down the bank, over the river and up the other side and on the Monteith station."

### One Wanted to Use a Gun

"Don't you get rough usage at times, especially when you go to repossess plants?" queried the reporter.

"Well," laughed Mr. Cronk, "that all depends on how you go about it. One man used a gun on us once. A few weeks later he bought my dinner. I don't go looking for trouble. It doesn't pay. The man with the gun was up near Bala. That was some years ago. I went in and took possession, and stayed right in his camp. I could see that he was simply trying to bluff me. I remained six days. At last I took my watch out and put it up to him to

# MARKET DEVELOPMENTS

# U.S. War Business Being Placed in Canada--Non-War Work Receives Scant Consideration

## The War-Grip Takes Entire Output of U.S. Pig Iron and Steel for 60 Days—Canadians Cannot Import Now for Warehouse Purposes — New Plants to Handle U.S. Orders Being Placed in Canadian Centres

THE war grip is felt to-day as it has never been felt before. The steel industry of Canada has already felt the action taken by the United States War Board in getting the Iron and Steel Institute to pledge its output at full speed for sixty days to war work. It means closer buying by Canadian jobbers. Orders will have to be placed for actual needs and import purchasing for warehouse purposes is now out of the question.

American war business is coming to Canada. The 155-mm. contracts have been placed in some cases, while others are pending. United States business coming to this side of the border will also include the 9.2 shell, one Toronto firm expecting to turn to this on completion of its 6-in. orders about the end of June. Machine tools and supplies are in big demand in consequence. High speed steel has already felt the trend and advances in cutters and drills are noted. In fact the high speed product requires very little urging to reach higher levels as the supply is never equal to the tremendous war-time demand.

The scarcity of small size boiler tubes is not relieved. There is a scarcity—a decided one—of skelp, and as long as the open-hearth output is insufficient to overcome this the scarcity will continue to be acute.

Evidence is not wanting that United States means what it says regarding giving preference to war orders. The American War Board this week entered the premises of a non-war manufacturer, took 8,000 tons of pig iron and transferred it to a war work plant.

Scrap material is strong, although the prices have not advanced. As giving an idea of the volume of business being done now in this market one Toronto firm, dealing in scrap metals, is about concluding an agreement with a munition firm for their cuttings for three months, the amount involved being not far from $200,000.

## MONTREAL FIRMS PREPARING TO HANDLE MORE AMERICAN ORDERS

Special to CANADIAN MACHINERY.

MONTREAL, Que., May 8.—Local industrial activity has been stimulated by the announcement that in all probability more American shell orders will be placed with Canadian firms. It seems unlikely that any 12-inch shells will be placed here, as the firm that was supposed to have received an order for this size will not proceed with this work owing to certain unfavorable conditions. Considerable activity is displayed in local machine circles and several plants here are busy constructing tools of a special character for the making of the 155 M.M. shells. Shipbuilding is abnormally active, but firms report continued difficulty in the securing of materials, particularly in connection with steel plates. River navigation is now in full swing, and has given much relief to railroad transportation; upper lake traffic has suffered a slight inconvenience in the destruction of one of the lower locks in the Lachine Canal, the gates having been carried away by the loss of control of the collier Henry B. Hall on the last day of April. With the exception of a few of the larger vessels no serious delay was experienced, as the lighter craft were transferred through the northern section of the canal. Local plants requiring the services of skilled workmen are experiencing some difficulty owing to the pronounced shortage. A maker of machine tools and gears reported to CANADIAN MACHINERY that it was almost impossible to secure men adapted for their work owing to the heavy demand in the munition plants.

### Steel

Canadian conditions in the steel activity, particularly in connection with the consumption, are becoming more and more acute owing to the conditions that prevail in the industry across the line. The difficulty of obtaining steel from points in the States increases as the demand of the American Government for urgent war requirements continues to grow; the needs at the present time are so abnormal that little material is now available for ordinary purposes. This condition is naturally reflected throughout Canada owing to the dependence of Canadian consumers on the production in the States. All the mills in this country are operating to the full extent of their capacity, but the output is more along the lines of lighter shapes and plates and steel for shell-making purposes. The bulk of the material that is required in the construction of the steel vessels must be obtained from the mills in the States. Dealers here are apparently not enthusiastic regarding the early future. The unsettled condition has had the tendency to create a nominal market and quotations remain unchanged and very firm.

### High Speed Steel

The present demand for high speed steel is just about normal, but manufacturers and dealers are anticipating further activity in the near future or as soon as the experimental stage of the new shell developments have advanced far enough for manufacturers to decide definitely as to the tooling operations. Shell makers are still in the market for considerable quantities of high speed tool steels, and the price is still around the average of $2.25 per lb.

### Metals

Meta's generally are developing strength and the demand is apparently increasing in volume. Better transportation has resulted in increased produc-

tion and delivery to consumers is more regular in character. Copper is steady, with the possibility of a revision in the fixed price. Tin is very strong and also uncertain owing to non-delivery of expected supplies. Spelter is developing strength. Lead has a weaker tendency. Antimony is in good demand and has a better undertone. Aluminum is firm and unchanged.

**Copper.**—Activity is normal, with prices firm. The situation in the States is without feature, although the trade is anticipating a slight advance on the first ensuing month when any contemplated change will go into effect. Just what action the Government will take is not yet known, but it is not unlikely that a concession of about 2c may be allowed to producers to meet the increased cost that has developed since the fixing of the initial price. The situation here is not marked by any special feature, and dealers continue to quote last week's prices—29c and 30c per lb.

**Tin.**—Uncertainty is the dominating feature in the tin situation, and it is this factor that is tending to place this metal in a relatively impossible position. The indefinite delivery of tin from England has placed the dealers here in a difficult position, as they are unable to establish a basis for their operations. Dealers' supplies here are gradually being reduced, and sales are made only to those in urgent need, and at present prices it might be said that little buying is done unless the requirements are absolutely essential. The rapid advance on the London market has been reflected on this side; no quotations are obtainable on the New York market, and dealers here have advanced their quotations to $1.25 per lb., this being an advance over last week's price of 15c per lb.

**Spelter.**—While the demand has not been pronounced, the market has a strong undertone and the tendency is upward. Dealers here report a very good market, and are inclined to think that an advance may be anticipated. Quotations are firm at 10c per lb.

**Lead.**—This metal is not active, and the outlook is for easier prices. Local quotations are firm at 9½c per lb.

**Antimony.**—The market is taking on a firmer tone, due to the better demand. The New York market has advanced ⅜c over the week, but local dealers are holding firm on the quotation of 15c per lb., reporting a stronger situation.

**Aluminum.**—The market is quiet and with a weaker tendency; local quotations are unchanged at 50c per lb.

### Machine Tools and Supplies

The activity in the demand for machine tools has shown an increase owing to the placing of additional orders for American shells. Some weeks ago it was anticipated that contracts would be placed in Canada for 12-inch shells, but owing to the difficulty regarding the supplying of forgings this class of shell has apparently been withdrawn as a possible Canadian product. Several Canadian plants are, however, preparing to start operations on the 9.2-inch for the American Government and renewals for 4.5-inch have been placed in comparatively large quantities; in addition to these contracts have been let for 155 M.M. shells, and the demand for suitable equipment has been quite brisk. One Montreal firm are busily engaged fitting out for the manufacture of these shells and have recently contracted for about 80 Desy turning lathes of special design. Dealers here report that the demand for machine tools is quite normal, and inquiries for medium heavy shell equipment during the past week have been above the average. General service tools are in fair demand, and the requirements for small supplies are still of considerable volume; transportation has been improved, but definite delivery is not yet a pronounced factor, and manufacturers are still handicapped from shortage of certain supplies.

### Scrap

Nothing of importance has developed in the market on old materials and business in general has been quiet. Dealers report that sales have been light, and consumers are apparently buying only what they require for immediate needs. The better conditions that have recently been granted to dealers in American markets has created renewed interest over there, but so far this tendency has not been shown in the Canadian situation. Business is normal in heavy melting steel scrap, and brass scraps are in good demand, but the general market is quiet. Quotations are unchanged and firm.

## POINTS IN WEEK'S MARKETING NOTES

**U. S. War Board took 8,000 tons of pig iron from non-war plant and shipped it to war work plant.**

**Pleasure autos are placed by U. S. in the non-war class.**

**War account orders placed by U. S. Government are running ahead of deliveries.**

**"Commercial Steel" orders getting a preference will include (1) orders for oil development and transportation, and (2) steel involved in agriculture.**

**U. S. business men aroused by report that Ontario Hydro-Electric energy is drawing U. S. firms to locate in this province.**

**Cars leaving U. S. points for Canada must be loaded to capacity.**

**Steel and pig iron supply of United States commandeered by the government, but Canadian war business will be protected, although non-war orders will be harder hit.**

**Advances in high-speed goods are again noted. Some of the cutters and drills go from list plus 40 to 60 on.**

**American orders for munitions are coming to Canada. Toronto plants now are preparing for the 155 mm., while one concern will change over from 6 inch to U. S. 9.2 about the end of June.**

**Canadian users of plate have been notified that they cannot purchase for warehouse purposes. The process from rollers to finished article must be made more direct.**

**Scrap metal prices, although not changed yet show a tendency to go to higher levels in some lines.**

**Steel plate prices are likely to revert to former high marks although Toronto lists are unchanged yet.**

**Boiler tubes are scarce and the situation is not improving. This is true especially of small sizes. The scarcity of skelp is given as the cause.**

## MUNITIONS ORDERS ARE COMING THROUGH

**The 155 M.M. Will be First Start, to be Followed by the 9.2 Order**

TORONTO.—The steady trend of prices that has been current for the past few weeks in the local market shows signs of breaking, and it begins to look as though the break were going to be on the upward plane. High speed goods in some lines go from 40 to 60 per cent. on list figures. Jobbers in steel plate say that although they have not advanced prices so far, they are about to do so. It was only a month ago that plate dropped from the ten-dollar mark to the nine (per hundred). It looks as though this figure would be of rather short duration, and although it is much higher than the fixed price quoted in the United States, the tendency is that the ten-dollar mark would be restored in a few days.

Dealers in scrap metals are in the same position. Local figures have not been advanced, but the tendency is towards higher price. The action of the American Government in making a demand for all material for war work for sixty days is, the dealers state, going to make a bigger demand for heavy melting steel and for its counterpart in scrap metals.

The munitions business keeps up a brisk demand in the machine tool and supply business. Orders for the 155 m.m. shell are being placed, and a new plant is being erected for one Toronto firm to do this class of work. Other plants that have been handling six-inch work are turning over to this business, for the 155 m.m. is in reality a slightly changed form of the six-inch, orders for which have formed the backbone of the muni-

time

### Steel May Go Up

at last
hun
Toronto although each
quot
The Canadian dealers have been informed by
at
warehouse
tion means that there is no chance now of passing any of this material into stock, as the situation is so imperative that it is necessary that all this material should pass into actual war construction as soon as possible after leaving the rollers. The effect of this is that the dealers are going to conserve the stock they have on hand by increasing the prices. Buying will be more limited than formerly, and every effort will be made to see the motive prompting the latest decree from the War Board is carried in practice. Boiler makers will also find that they must carry on their business on a more hand to mouth scale than ever, and their purchases will have to be made largely for the special jobs that they have in hand. It may make work a little slower, as it will be impossible to keep stocks on hand in anticipation of orders that might be legitimately expected to come in.

The supply of tubes, especially for the smaller sizes, around two inches, does not improve, and prospects are not good for any betterment in this direction. The four-inch shipments are coming in a little better, some cars of these having reached Toronto to-day. The scarcity of small tubes can probably go right back and be blamed on the shortage of all material that passes through the open hearth furnaces. Just now there is a very de-
situation is bad in consequence. Boat owners are in a better position than might be imagined, as they anticipated the situation and made their purchases for winter repairs in good season.

### Scrap Metals

Dealers are not anxious to take on much business just now until they are a little more certain of the future prices. In common with other products, the scrap metal stock is coming to the point where higher values are in sight. One dealer said to MACHINERY this morning, "We are paying more for scrap metals in
than they would sell for in the United States centres." He produced correspondence to prove his point, and had he sold at the prices offered in Boston he would have lost by the transaction. This same dealer intimated that a contract was in the making whereby his firm would take in cuttings from a munition plant that would run into figures from $150,000 to $200,000 in a period of three months, giving some idea of the extent of the trade in this direction. Some copper and brass in the way of scrap metal crosses the border, this being possible under license only. Other lines are barred by the Canadian embargo. The dealers anticipate the next move will bring higher figures, anticipating a demand for heavy melting steel, although there is the fixed value of $24, past which the price cannot go. The action of the United States Government in using all the mill output for sixty days will mean increases in the scrap trade, at least that is the interpretation of the dealers.

### Machine Tools and Supplies

High speed goods are quoted up again, the incessant demand for war machinery being undoubtedly the cause. Brown & Sharpe cutters have been 40 on the list price, but to-day the price is given out as plus 60. Drills are up aagin, and the double list is used to indicate their price. The placing of American munitions orders in Canada keeps the supply houses busy. The business offering now consists largely in the 155 m.m. on American orders, and at least one plant in Toronto is being fitted out for this business. American business is desirable now, highly so, as every dollar of this sort helps to correct the balance of trade which has come to the point where it is a matter of serious inconvenience.

One Toronto firm that has had a very large and successful run on the 6-inch business, is making preparations now to turn over to American business, the 9.2 being the size they will turn out.

### Metals

Prices of non-ferrous metals, locally, are holding firm, but tin is the only one that has advanced. The tin situation continues acute with no relief in sight. A meeting was held in Washington last week to consider the question of raising the prices of copper, but no decision was arrived at. In the meantime the market is steady and firm. Lead, spelter, antimony and aluminum are steady and unchanged. Business locally continues brisk.

**Copper.**—The War Industries Board and the copper interests met in conference in Washington last Thursday but adjourned until May 22 without arriving at any decision in regard to revising the fixed price of copper. It it understood that an increase from 23½c to 24½c a pound will be asked, the advance to be used chiefly to offset the higher refinery costs. Consumers are reported to be well covered by contract and apparently there is no shortage of metal for any purpose. Lake and electrolytic are quoted at 28½c and casting at 28c per pound.

**Tin.**—The tin situation is unchanged and the shortage continues acute. There is no spot metal for any grade for sale and only Chinese tin apparently can now be purchased for future shipment from the Far East. Tin has again advanced locally and is now quoted at $1.15 per pound or 10c higher than last week.

**Spelter.**—The market is firmer, due to a report that the U. S. Government has purchased a large quantity of high grade spelter, 9,000 tons it is said, at around 10c, St. Louis basis. Prime Western spelter continues quiet and the market featureless. The local price of spelter is unchanged at 9½c per pound.

**Lead.**—The primary market is easier and lower prices are anticipated. The weakness in the market is attributed to an increase in Mexican production and lack of buying for domestic account, the latter being probably due to the expectation that the market will go lower. In the meantime local price of lead is unchanged at 8½c per pound.

**Antimony.**—The demand is more active and firmer again. It is understood that the U. S. Government has asked bids on 1,000 tons of antimony for May-June delivery. Prices here are firm and unchanged at 16c per pound.

**Aluminum.** — The market continues steady. Practically all the aluminum output is being taken by the U. S. Government at the fixed price of 32c for 98 to 99 per cent., in 50 ton lots: Local price 50c per pound.

# THERE'S ALWAYS A NEW CROP COMING ON TO FALL FOR THE SHOP JOKES

On being made acquainted with some of the difficulties that superintendents and foremen are experiencing at present, in training some of the new men in their employ, for better efficiency, the writer was reminded of an incident that happened in a large plant in central Ontario some years ago, where a young fellow (green) was engaged to work in a repair gang, the duties of which took them to all portions of the plant. On the afternoon of the first day some of the other men, wishing to have some fun with the new recruit, advised him he would require to obtain a set of calipers for certain work he would be called upon to do. Asking where he could secure these, he was instructed to apply to the blacksmith, who would willingly make a pair for him. The smith, being an obliging fellow, and one of those who appreciated a joke, asked the young chap what kind of caliper he desired, inside or outside. Said the young man, "Well, just now I am working in the shop and will need an inside pair, but I will be working in the yard to-morrow and then I will require an outside pair." The smith had considerable difficulty in suppressing his amusement but advised the fellow that he would do his best to make him the tools. The outside job, however, did not require the services of the outside calipers.

# CANADIAN WANTS WILL BE PROTECTED

**United States Order Means All Energy Must Go to War Work at Once**

Special to CANADIAN MACHINERY.

WASHINGTON, May 8.—The entire steel and pig iron supply of the United States has been virtually commandeered by the Government, for war purposes. This action taken by the War Industries Board has just become known here. All steel supplies not used for war purposes will be distributed to the non-war industries through the War Industries Board. This action is taken with the consent of the steel manufacturers.

J. Leonard Replogle, director of steel for the War Industries Board, this week held a meeting with the large steel producers when they gave their promise to devote their entire capacity to producing steel for war purposes. The War Industries Board is given the right to direct the shipment of completed steel, and the entire steel supply of the nation will be disposed of as the War Industries Board sees fit. The first example of the working of the new plan came on Friday when eight thousand tons of pig iron were taken from one steel mill which has been furnishing supplies for non-war work and shipped to a plant where war work is being done.

Pleasure automobiles have been placed in the class of non-war work and already there has been a curtailment of steel for this purpose.

### To Protect Canada

Supplies of steel for Canadian war work will be insured. The War Industries Board, working in co-operation with the Canadian War Mission and other Canadian official bodies, will work in close co-operation so that there will be no restriction on the supplying of steel and pig iron for those Canadian industries engaged in war work. Non-war industries in Canada will be placed on the same basis as the non-war industries of the United States.

Congress is awakened to the need for water power legislation which will enable the development of America's greatest water power resources. This sudden impetus has been given to Congress by statements made on the floor by Senator Jones of Washington and others to the effect that American industries, lacking power, are moving their businesses to Canada. Sir Adam Beck of the Hydro-Electric Commission of the Province of Ontario, testified before a Congressional committee recently and described the impetus given to the industrial growth in Canada through the delivery of 315,000 Hydro-electric horsepower generated at Niagara Falls. He announced that further water power developments were to be undertaken that would increase the production of power in Ontario by 1921 to 750,000 horsepower.

### Sir Adam's Speech

Sir Adam Beck spoke as follows:—"I wish to tell you that we are now short in the Niagara district, in the Province of Ontario, at least 100,000 horsepower that is essential and necessary at this time, and largely for munition purposes. We have three large American plants on the Canadian side manufacturing explosives and essentials in the Carbide Company, the Electro-Metals Company, and the Cynamide Company and they use between them in the neighborhood of 75,000 horsepower. We have received repeated appeals from Washington to increase these quantities and we have done everything to curtail the use of power so that these large industries can keep their businesses going.

"Of course if we were as greedy as we might be—and I suppose we are human—we would not encourage in any way by an object lesson such as we have here to have you nationalize the water powers on the American side, because these large industries you have will be more likely to establish branch industries in the Province of Ontario to take care of their foreign trade, having labor conditions equally favorable and a much cheaper price of electricity and no fear of an increase in that price of electricity. We have a large industry now on the St. Lawrence in the British Chemical Company. It is American, however, entirely. They are establishing a large industry and only using 4,000, but want 8,000. They are quite safe in assuming that the price will not be raised and that they will not be deprived of that power."

### To Develop Power

This statement made by Sir Adam Beck has aroused Congress to action and it appears now that legislation will soon be passed to develop the waterpower resources on the American side of the St. Lawrence.

The Shipping Board has announced that thirty-four Great Lake steamers have this week been ordered removed to the Atlantic trade.

The report of the progress made in the construction of ships for the month of April as announced by the United States Shipping Board shows that during that month there was a construction of 236,000 deadweight tons. The best previous record for construction during one month was that of June of last year when there was a construction of 152,136 deadweight tons. The report shows that during the last week in April there was a construction of 41,105 deadweight tons of both steel and wooden vessels.

### Must Load to Capacity

The President has this week appointed the members of the War Finance Corporation who will have control of nearly five billions of dollars which is to be used for the aid of industries in the United States engaged in war work.

Orders have been issued by the Interstate Commerce Commission regarding the loading of cars for Canadian points. The regulations issued provide for capacity loading for all cars.

Manufacturers of all non-essential war industries are now being called to Washington to confer with the Fuel Administration regarding orders which are to be issued shortly regarding the curtailment of coal shipments to non-essential industries.

# LITTLE STEEL NOW FOR NON-WAR WORK

**Iron and Steel Makers Pledged to Devote Entire Plants to War Orders**

Special to CANADIAN MACHINERY.

NEW YORK, May 8th.—On Monday of this week every member of the Iron & Steel Institute received a circular letter from President Elbert H. Gary, in which was enclosed a pledge, acquainting them with the result of the meeting held April 26th between 50 of the principal steel manufacturing companies' representatives, and J. L. Replogle, director of

# DIRECT AND INDIRECT CONTRACTS CLOSELY RELATED IN THE WAR WORK

Appreciation of the fact that manufacturers who have direct war contracts are dependent to a very large extent upon those who have indirect contracts would save much time under pressing conditions, said a manufacturer to CANADIAN MACHINERY to-day. He has one of those so-called indirect contracts for the production of very essential parts, while another manufacturer has the master contract calling for the delivery of the completed work.

"It seems impossible to make department heads understand," said he, "that the whole job may be tied up if work on these secondary contracts is subjected to red tape methods. There seems to be a rule that materials must first go to direct contracts.

### Causes Much Delay

"This, in my opinion, has been the cause of much of the delay in the United States. Men who direct this work must realize that efficient production calls for co-operation in the industries affected, and that the main show cannot go ahead while certain necessary parts are held up. To illustrate: If a man gets a contract for wagons, he will not make very much progress if the man who supplies him with certain parts, patented or otherwise, is denied material. It is equally unreasonable if electric power is denied an indirect contract, while the main job may be waiting for parts. Too literal a construction is placed on the terms "direct" and "indirect" and too little thought given to conditions that impose inter-dependence.

"In Canada it is not so bad, and it is to be hoped that in U. S. the problem will be worked out along more practical lines than heretofore. It might be a good plan for the manufacturers themselves to take united action in presenting conditions before the proper people."

minutes of the meeting, held the preceding [illegible] by Judge Gary. Mr. Replogle's remarks brought out the [illegible] given in last week's letter to CANADIAN MACHINERY.

### They Have the Facts

Steel manufacturers, themselves, to within the last few days, have believed that the Government would call for 100 per cent. of the steel output for war purposes [illegible] but they are now aroused to the full magnitude of war requirements and the significance of the revelations made by the Director of Steel Supplies. Of course, some shipments of steel products previously rolled, will be made to consumers, but hereafter little or no steel will be available for [illegible] engaged in war work, except on special permit from the Government. War needs, according to Mr. Replogle, now actually in hand will absorb all rolled steel output for the next eight months.

### Very Large Figures

One of the surprising statements made by Mr. Replogle referred to the construction of military buildings and plans now under development which will call for structural steel exceeding by 20 per cent. the total steel used in building construction in the entire United States during 1915, 1916 and 1917. If this estimate is correct, Government structural requirements will amount to 3,200,000 tons approximately, but this probably covers structures which will be built in 1919 and 1920 as well as during the current year.

Orders for 100,000 freight cars, 70,000 of which were placed this week, will call for 1,000,000 tons of steel and the 1,300 locomotives which have been ordered or are pending will call for 260,000 tons of steel. Most of this tonnage was included in Mr. Replogle's total of approximately 20,000,000 tons.

### For Machine Tools

Government requirements of machine tools in the next few months will be enormous. It is estimated that purchases of necessary machinery mainly as a result of the contracts to be placed by the Ordnance Bureau of the War Department, will call for the expenditure of $80,000,000. In the last week the Navy Department has ordered $600,000 worth [illegible] orders for cranes. Contractors holding orders for military buildings have also inery which in the aggregate have called for the expenditure of upward of $800,000.

The Wright-Martin Aircraft Corp., New Brunswick, N.J., has finally distributed orders for 400 machine tools among dealers and manufacturers calling for the expenditure of $1,000,000. The Aircraft Corp, it is now understood will utilize the Government factory at Long Island City, formery owned by the General Vehicle Co., to manufacture a heavy type of Hispano-Suiza motors for the Government. The Savage Arms Corp. and several other gun makers in New England, are buying more machinery to rush production of machine guns. Many machinery shops having sub-contracts for gun parts, are also in the market for tools.

## THE WAR GRIP GETS THE STEEL OUTPUT

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., May 8. — The grip of the Government upon the steel supply has become complete. All producers have acceded to the demand of the authorities that every available ton of steel be shipped for account of the Government and its Allies. Following the meeting in New York, Friday, April 26, between J. Leonard Replogle, Director of Steel Supplies, and about fifty representative steel manufacturers, Judge Gary, as president of the American Iron and Steel Institute, sent a request to each manufacturer to do his utmost, and asked that a pledge to the effect be signed.

As illustrative of the situation, the Carnegie Steel Company last week made the statement that every ton of open-hearth ingots the company cast, except ingots rejected as not coming up to specifications, was being applied to orders of the Government and its Allies, and the rejections were very few. Apart from the rejected ingots there is left, of course, the crops from ingots intended for shell steel, such crops being available for rolling a limited tonnage of commercial steel, such as light rails, and in addition there is the production of Bessemer steel not taken up by war requirements. Only one-fourth of the total steel output of the country, however, is in the form of Bessemer steel, and the tin plate requirements absorb a great deal of that, while the Railroad Administration apparently intends to take Bessemer rails only, so as to conserve open-hearth steel for purposes which demand that grade of steel. This is the situation as applied to the largest single producer, but it should be noted that there are small producers having a limited range of finished products, and of some of these products the Government cannot possibly use the entire tonnage. In the final line-up, however, there may not be a great deal of such products available for commercial purposes. For illustration, the Government cannot use anything like the normal tonnage of wire produced in the country, and there are some mills that can make little except wire, but the mills that can make wire only may be given the wire orders, and mills that can divert steel from their wire departments to other departments making finished products greatly needed by the Government may be pushed with orders for the other products so that their wire production will be light.

### A Complete Change

A restrospective glance shows that the situation and prospects as to supplies of steel for the so-called "commercial" purposes has changed entirely in the past 30 days. At the beginning of April the outlook, in the minds of many observers, and probably the great majority of steel producers, was that there would be an ample supply of steel for war purposes, and a surplus that would perhaps be entirely sufficient for commercial purposes. This expectation was based on the large increase that had occurred in shipments, through the passing of a winter which had so greatly cut down production, but it did not allow sufficiently for the increase in commercial demand that evidently was occurring at the same time nor, more important still in the mind of the Director of Steel supplies, did it allow for the expanding needs of the Government and its Allies. While all producers are probably not converted to the idea that steel is going to be scarce continuously, the philosophy of the remainder is that their duty is to act, and furnish all the steel asked for, and if meanwhile they cherish the theory that a couple of months of such action will result in the authorities relaxing their pressure, no harm will have been done by their entertaining the theory.

### War Orders Heavy

It is understood that the orders currently placed by the Government, or placed indirectly for war account, are regularly running ahead of the deliveries. In several important lines the war orders on books are equal to several months of shipments at the present rate. Considering these circumstances, together with the fact that the Allies abroad desire more and more steel, as available, by reason of the shortage of man power at home, and the further fact that the authorities at Washington wish to play safe this summer and fall and accumulate steel if possible against any traffic difficulties next winter, it becomes clear that the war requirements of the next few months are going to prove much heavier, in proportion to productive capacity, than was assumed only recently.

### Export Steel

The pledge taken by the steel producers, to divert all possible steel to the war work, has a particular bearing upon shipments of commercial steel for export. Such material does not come under the price agreement, and thus if the producer exercised his choice it would frequently be to ship such steel, on account of the higher price involved. This is prevented by the pledge.

On the other hand the authorities at Washington, as indicated in last report,

(Continued on page 69.)

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

# Japan Turning to Canada to Secure Needed Equipment for Her Shipbuilding Plants

## S. Noda, President of Roku-Roku Shoten, Ltd., Tokyo, Spent Some Time Looking Over the Situation in Toronto. Situation in China Makes the Development of Japan a Difficult Matter.

JAPANESE [illegible] are turning to the Canadian industry, have turned [illegible] The reason for this is probably necessity as much as preference. The Japanese firms are finding it increasingly hard to secure shipments from the firms in the United States, with which they have been doing business for many years, on account of the regulations that are holding the output of American plants at the disposal of the United States Government for war purposes.

S. Noda, president of Roku-Roku Shoten, Ltd., machinery merchants of Tokyo, Japan, spent a few days in Toronto during the week. Speaking to a representative of CANADIAN MACHINERY, through which publication he first became familiar with the lines made in this country, Mr. Noda stated that there was a very great demand in his country at present for machine tools for the shipbuilding enterprises. "The bottoms that are being built are principally freighters of about ten thousand tons, and are on the order of the Japanese ship owners. The machines we want are lathes, mostly big ones, drills, grinders, planers, etc. We also need steel plates in greater quantities than we are now getting them, and pig iron is a scarce article with us."

### A Capable Merchant

Mr. Noda impresses one as bright, capable, and quite familiar with our methods of doing business. He speaks good English, is very anxious to learn all he can about the events that are taking place in Canada, and is well versed on the far eastern situation, especially regarding the relations between Japan and China.

"I have been buying machinery in the United States for a number of years. The Roku-Roku Shoten has been organized for over fifteen years, and handles nearly all lines necesary for shipbuilding and other industries. Of recent months we have found it very hard to get the goods we wanted from the United States, as the shipping regulations are very strict. I decided to see what we could do in Canada. We had been in touch with firms here through your paper, CANADIAN MACHINERY, as you had always sent us your export numbers. I am meeting many men here as possible, but my [illegible]e is limited, but we will have another representative in this country before very long to go into the business more thoroughly."

### The Limits are Placed

"Will Japan develop industrially to the point where she will not be an importing nation?" queried the reporter.

"Not for a long time to come," replied Mr. Noda. "You must understand the situation before you see the reason for my answer. Japan itself is not a large country, but the people there are very energetic. We feel that China is the place where we should be able to get the raw materials, and that is where the trouble comes in, and there is small chance of any improvement until there is some settled policy for the future of China. For instance China is rich in mineral wealth. We want to get iron ore there. We can also secure coal for the making of coke and limestone. Why could we not make pig iron and steel? Simply this reason stops us—each province of China seems to be separate and apart from the other. There is no central body to deal with there, and there is no assurance for protecting large investments that would be necessary before we could go in and get a sufficient output of raw material. The powers will have to come together on the future of China. While the feeling between China and Japan is better than it has been for a long time, there is always that element of uncertainty that stops and hinders any development that our people have in view, and in that way we are held back very much."

### Steel Prices are High

Answering a question about the price of ship plate in Japan, Mr. Noda said that it was now worth about $200 a ton. That is based on imports from the United States, where the figures are lower than here. "We find it hard to secure plate now, and I would like you to tell me," continued Mr. Noda with a laugh, "where I could get a whole lot of plate right away as well as a big shipment of pig iron. We are very short on these. Not long ago we made an agreement with the United States whereby we receive one ton of plate from them and in return send back one ton in shipping bottom. We are making quite a bit of plate but nothing to what we can use. Japan probably turns out one million tons of plate in a year. Of course we have the advantage in the way of the price paid for labor that is put into the building of ships."

"And what wages do you pay?" asked MACHINERY.

"They vary," replied Mr. Noda, "but as a general thing it would be safe to say that fifty cents a day was the average paid for labor. Some lines that require greater skill and training will get more, but others again where nothing but rough work is done will get less than that. Of course living does not cost anything like as much as it does here in Canada. The poorer people of Japan can rent a house from five dollars a month up. For the better houses we will pay about $15 and perhaps more. There's one thing I notice here. I think you people eat too many kinds of stuff. In a hotel there are a great many more dishes prepared than a person really needs. We live much more simply than you do, perhaps we eat just as much, but the variety is less. I think it would be safe to say that a man could live on a little more than 25 cents a day in Japan right now."

### Japan and the War

"Japan is greatly interested in the war," remarked the visitor from Japan. "The people there are anxious to have it over with, as it is impossible to go ahead with any plans for the future as long as the war keeps on. Japan is ready and anxious to do what she can and there is no question as to the feeling of the people toward the cause of the Allies. There was much said a little while ago about Japan sending troops into Siberia when the Russian army left the field. I do not think the Japanese would do that unless they were acting with the rest of the Alies. They would not go in there themselves, because they want to act with the other armies that are fighting with Britain now. But Japan is going ahead, and will do so more after the war than she has ever done before. There should be a chance for the manufacturers of Canada to do more business with our country than they have ever done before. We need machinery, machine tools and supplies, wood pulp, lumber of all kinds, pig iron, condensed milk, and I should think we could buy a lot of good horses, especially the heavy ones. You see the motor car is not used in Japan as it is here. I don't suppose there are over two thousand cars in the whole country. They are generally the property of the better class only. I shall come to Canada again," said Mr. Noda in conclusion, "and next time I shall spend more time here. It is a great country and I am much pleased with what I have seen of it."

---

**Wilfrid U. Hollingworth**, foreman at the Dominion Bridge, Montreal, died at the Lachine General Hospital on May 3. Mr. Hollingworth had been ailing for some time, and on the advice of his physician had resigned his position and was on the point of going west to take up farming. He was a native of Widnes, England, and came to this country eight years ago, taking a position with the above company.

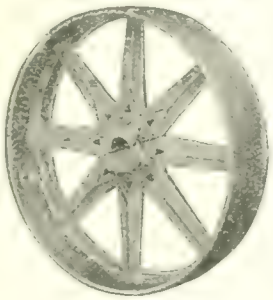
# THE A. R. WILLIAMS MACHINERY CO. LTD

64 FRONT ST., W. TORONTO, ONT.

SALES SUPPLY DEPARTMENT SERVICE

# WE HAVE THE GOODS IN STOCK

We have one of the largest stocks of Machinery Supplies in Canada, including Machine Shop Woodworking Factory, Power House Supplies, etc.



## "AMERICAN"

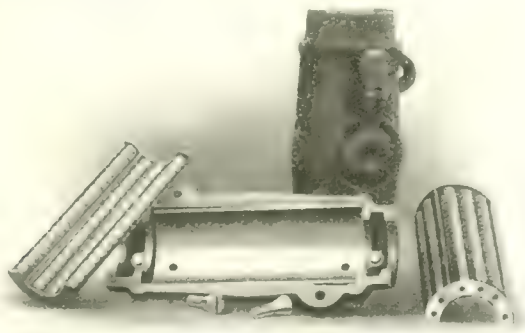
**Steel Split Pulleys** are made of Steel,—a material used the world over for structures demanding lightness combined with strength. They transmit maximum power with minimum belt slip. AMERICAN Pulleys are guaranteed to perform double belt duty under any conditions not demanding a special pulley.

## Gear Cutters, Milling Cutters, End Mills

We make it a rule to always have a complete stock of these cutters. Therefore, it is very seldom you are unable to get what you require immediately out of [illegible] stock.

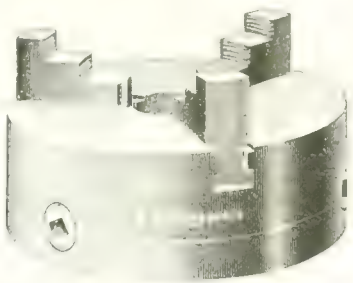
## "HYATT"

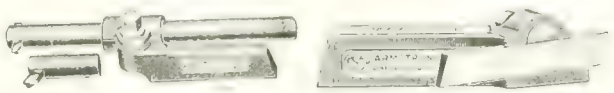
**"HYATT" Flexible Roller Bearings** save you from 60 to 75% of friction, save Oil and Labor. The Rollers operate on the shaft. There are no Collars nor Sleeves, nor Bushings—nothing to give trouble. "HYATT," the bearing of Highest Practical Efficiency. Write us for list of satisfied users of above bearings.



## LATHE CHUCKS

All the popular makes of both Drill and Lathe Chucks carried in stock in all sizes and styles. Also we can give you immediate delivery from stock on all sizes and styles of Twist Drills, Reamers, Taps, Screw Plates, etc., etc.

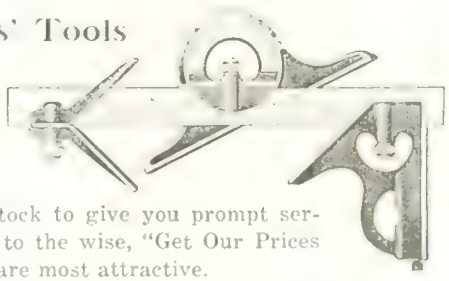




## "ARMSTRONG" Tool Holders

Heavy loss in time and material is inseparable from the use of forged lathe tools. Therefore, use "Armstrong" Tool Holders and avoid this loss. "Armstrong" Tool Holders are a complete Economical and Efficient Equipment of High Speed Tools for Turning, Boring, Threading, Knurling, Cutting Off, Planing, Slotting and Drilling metals. A most extensive stock of these Tool Holders kept in stock to give you prompt service.

## Mechanics' Tools



We have practically everything you will require in this line right in stock to give you prompt service. A word to the wise, "Get Our Prices First." They are most attractive.

**Complete line of TRANSMISSION EQUIPMENT, POWER HOUSE, MILL and FACTORY SUPPLIES always in stock.**

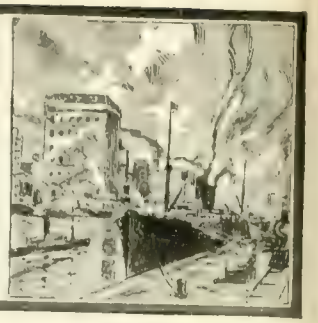
# INDUSTRIAL NEWS

## NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES



## ENGINEERING

**Thorold, Ont.**—The Beaver Board Co. [illegible]

**Toronto, Ont.**—The Chapman Double Ball Bearing Co., Sorauren Avenue, will build an addition to its plant to cost [illegible]

**Halifax, N.S.**—The Halifax Vulcanizing Works proposes to build a vulcanizing plant on Grafton Street at a cost of [illegible]

**Montreal, Que.**—The Montreal Locomotive Works will build an addition to their foundry at Longue Pointe. The Dominion Bridge Co. have the steel contract.

**Blenheim, Ont.**—E. W. Knight, Talbot Street, has secured a site on which he will build a two-storey brick and concrete garage and auto repair shop, to cost $10,000.

**Grand Mere, P.Q.**—The Laurentide Power Co. have under consideration the installation of three additional units of 20,000 h.p. each, making the total capacity 180,000 h.p.

**Orillia, Ont.**—The E. Long Mfg. Co., manufacturers of sawmill machinery, tools, etc., Queen Street, will build a two-storey factory, to cost about $60,000. W. W. McBain is secretary-treasurer of the company.

**Toronto, Ont.**—The Northlight Motor Co., Wesley Building, will establish a plant in Toronto for the manufacture of marine engines, and is in the market for screw cutting lathe, large drill, planer, milling machine, 30-inch band saw, wood turning lathe, and universal wood trimmer.

**Quebec, Que.**—Quinlan & Robertson, who are building four wooden ships of 2,500 tons each, have commenced work on the fitting out of machine shops at the Louise Docks. J. A. German is in charge of the work. The machine shops will be used in connection with the installation of the engines and boilers in the above shops.

**Vancouver, B.C.**—The Taylor Engineering Co. of this city has the contract for the construction of a floating dry dock. The dock will have a capacity of 4,500 tons and will be capable of completely docking vessels up to 4,500 tons, but repairs may be carried out on ves- [illegible] either end. The cost will be $750,000.

**Halifax, N.S.**—The foundry of Hillis & Sons, Ltd., which was destroyed by explosion last December, is to be rebuilt on the Kemp Road. It will manufacture Richmond ranges and foundry products of all kinds. Contracts for a temporary foundry and machine shop have been awarded to the Eastern Investment Corporation, Halifax, and work will begin at once.

**Sydney, N.S.**—The Dominion Coal Co. contemplate several extensions and improvements to their electrical equipment during the summer months. A central station is to be erected at New Waterford, and from this point transmission lines will be run to the locations requiring current. It is expected that electricity will also replace steam for haulage purposes.

**Midland, Ont.**—The smelter at Midland, which has lain idle for several years, has been acquired by Midland, Cleveland and Duluth interests. Employees of the new company are already preparing the premises for the new machinery and appliances, which will be rushed forward with all possible despatch. The company will manufacture pig iron, and hope to be in full operation within two months.

**Toronto, Ont.**—The site recently purchased for a munitions plant, situated near the G.T.R. at East Toronto and covering an area of 3¾ acres, cost $34,000, according to the statement of the vendor, J. B. Harris, Danforth avenue. The building will be erected shortly and plans and specifications are now being prepared. The machinery alone will cost $360,000 ,and will be used in the manufacture of large shells.

**Preston, Ont.**—The Hydro Commission, in view of the shortage of electric power, has asked the Grand River Railway to put their steam plant into commission and thereby reduce their electric consumption by 400 h.p. The steam plant is in need of repairs, however, and the order is not being enforced for the present, though May 15 is the date mentioned as the one on which the reduction should be inaugurated.

**Vancouver, B.C.**—By the provisions of the ore bounties bill passed at the concluding session of the house in Victoria a decided boon is given to the iron industry in the coast province. The province is given power in the measure to give a bonus of three dollars per ton of pig iron which is made in British Columbia from B. C. ore. In speaking in the house on the bill William Sloan, minister of mines, stated that there was sufficient iron ore in sight in the province to insure production for twenty-five years.

**Brantford, Ont.**—Mayor Macbride has received assurances from Ottawa that the estimates for the Port Dover harbor improvements will be brought down in the supplementary lists. W. F. Cockshutt, M.P., has written that the promise of assistance made to the Grand River Valley deputation by Hon. Frank Carvell will be carried out, and that commencement of the work at the harbor may be expected this year. The exclusion of Port Dover from the estimates recently brought down caused a protest from this and other centres affected.

## ELECTRICAL

**Barrington, N.S.**—Town Council contemplate the erection of an electric light and power plant to cost $8,000.

**New Westminster, B.C.** City Council contemplate repairs costing $5,000 to electric light system at the Queen's Park.

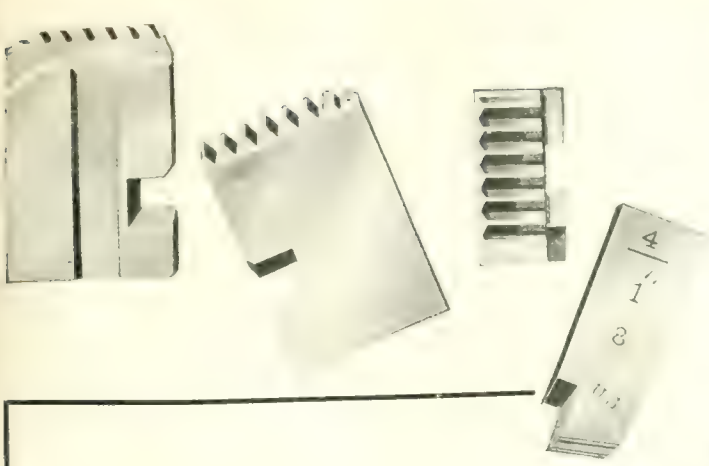
**Niagara Falls, Ont.**—Niagara District Independent Telephone Co., which has served farmers for many years, has decided to sell out to the Bell Co. The price fixed is $27,000, and it is expected the deal will be put through at the ne meeting.

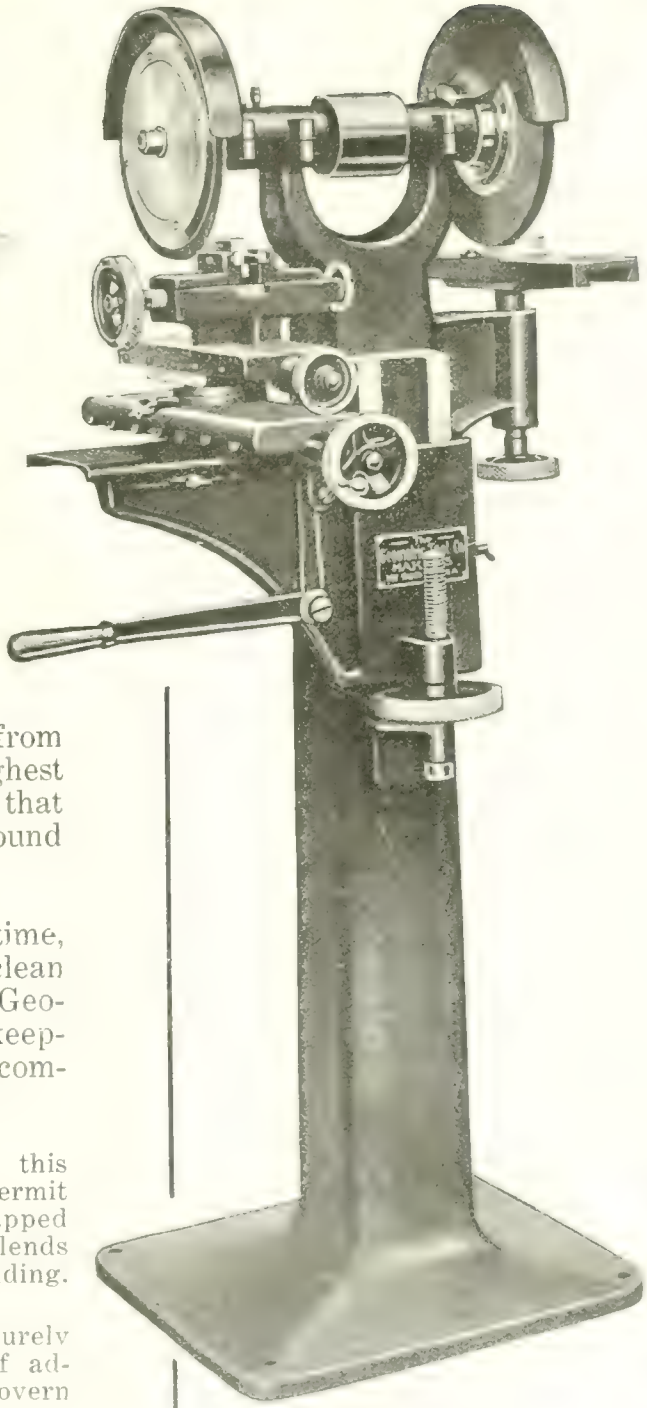
**Saskatoon, Sask.**—Telephone contractors estimate that approximately 2,000 miles of rural telephone lines will be built in Saskatchewan this season at an approximate cost of $250,000. The lines to be erected are chiefly extensions and completions of last year's work. Very little new work is being undertaken because the local government board is not authorizing any new telephone construction. The contractors estimate that if the local government board would authorize the expenditures there would be at least 5,000 additional miles of rural lines constructed in the province, at an approximate cost of $1,375,000 before August 20.

## MUNICIPAL

**Halifax, N.S.**—The Board of Control has requested the release of Major E. W. Doane, city engineer, from military service overseas.

**St. Thomas, Ont.**—Many of the big hydro power users will have to go back to steam shortly, in order to meet the demands of the power controller. Two of the latest to be affected are the Michigan Central Railway and the Pere Marquette. The St. Thomas waterworks system will





# Sharp Chasers Cut Clean Threads

Accurate, uniform threads result only from dies which are maintained in the highest state of cutting efficiency. This means that chasers must be kept sharp, and ground uniformly.

Even if just touched up from time to time, the chasers respond splendidly, with clean threads. And with this machine—the Geometric Chaser Grinder—the matter of keeping threading tools up to scratch is a comparatively simple matter.

Any make of chaser can be ground on this adaptable machine. The two wheels permit the easy grinding of both milled and tapped chasers. In addition, the plain wheel lends itself readily to various kinds of tool grinding.

Uniform grinding of a set of chasers is purely a mechanical matter through the use of adjustments which can be accurately set to govern the grinding of an entire set of chasers.

***The Catalog describing this machine is a mine of information on chaser grinding. Write for it.***

**THE GEOMETRIC TOOL COMPANY**
**NEW HAVEN CONNECTICUT**

***Canadian Agents:***

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

Chatham, Ont.—A [illegible] of the Hydro power users in Chatham is being [illegible] the Public Utilities Commission to ascertain just what power is being used and what might be wanted if there was an increase possible. A record is being made of the product of the various companies and other details connected with the plants. It is reported that similar reports are being compiled in other Western Ontario towns and cities and it is presumed the report will have some connection with the requests being made for more power, because of the order cutting off natural gas on July 1 next.

**Regina, Sask.**—The City Commissioners have been authorized to endeavor to arrange a thirty-day option on the $175,000 electric light unit which the council has been asked to purchase to ensure a sufficient supply of energy to meet the anticipated demands of the coming winter. The city has received offers of two American machines, one of which is ready for immediate delivery, consisting of a General Electric Co. turbine and a Westinghouse condenser, and the other, which will be ready for delivery about September, consisting of a Westinghouse turbine and a Wheeler condenser. The price of the two units is within $2,000 of the same figure. The officials reported that they would sooner have had a combination of one of the turbines with the other condenser, but the owner of the equipment would not consider this proposal.

## PERSONAL

**G. W. Ketter** has joined the staff of the Electric Furnace Construction Co., Philadelphia, having resigned his position with the British Forgings Co., Ltd., Toronto, Ont.

**Herbert A. Jackson** was recently elected president of the Chicago Pneumatic Tool Co., Chicago, to succeed W. O. Duntley, [illegible] He was born in Bethlehem, Conn., July 7, 1881.

**Edward F. Fauquier**, one of the most prominent of Canada's railway contractors, died at Ottawa on Sunday in his 63rd year. He was a son of the late Emilius Fauquier, of Woodstock, Ont.

**Capt. T. S. Scott**, No. 5 F.C.C.E., has been ordered to report at Halifax to aid in the reconstruction work in that city. Capt. Scott has been professor of civil engineering at Queen's University, Kingston, for several years.

**James M. Smith** now has charge of the shipbuilding plant of the Canadian Car & Foundry Co., Fort William, Ont., which expects to turn out 12 trawlers for the French Government before the end of the 1918 season.

Capt. John B. Forrest, [illegible] years old, master mariner for more than thirty years, died last Saturday at his [illegible] due to heart disease. A son of the late Capt. Robert Forrest, he was born at Sandwich, Ont.

**Mr. J. M. Riordan**, until recently sales engineer of the Grant Lees Gear Co., of Cleveland, and formerly representing the Fellows Gear Shaper Co., of Springfield, Vermont, in the Central States, is now connected with the sales organization of the Cleveland Milling Machine Co., 18511 Euclid avenue, Cleveland, Ohio.

**J. T. Edmond**, formerly with the West Coast Navigation Co., has been appointed ferry superintendent at North Vancouver, B.C. Mr. Edmond is 37 years of age, and served his apprenticeship as marine engineer with the firm of Hepple & Co., South Shields, England. For over a year he was marine engineer with the West Coast Navigation Company, and also served with Moore & Scott, San Francisco, and other prominent firms.

**E. C. Peck**, superintendent of the Cleveland Twist Drill Co., has been appointed a lieutenant-colonel in the Engineering Bureau of the U. S. Ordnance Department. Mr. Peck will have charge of the gauges used in the production of munitions and kindred materials for the above department. His duties will be the supervision of design of gauges and the setting of limits of variance which will be satisfactory to both manufacturer and the Ordnance Department itself.

**Joseph Bickerstaff**, manager of the Elm Cutting Oil Co., King St. E., Toronto, and his family of boys, have a military record to be proud of. Mr. Bickerstaff himself enlisted with the R. C. H. A. in the early part of the war, but was discharged on account of being too old. Of the boys, Everard M. Bickerstaff, the eldest son, was killed at St. Julien while serving in the 3rd Battalion. Joseph R. Bickerstaff, the second son, has just returned to Canada, after having been severely wounded at Vimy Ridge in April, 1917. The youngest son, Harold W., now assistant manager of the Elm Oil Co., was wounded and won the Military Medal on the Somme with the 19th Battalion for holding up a German detachment until the arrival of British reinforcements.

## TRADE GOSSIP

**Ottawa, Ont.**—The British Columbia members and delegation will meet the reconstruction committee of the cabinet here to present their case for the establishment of a British Columbia shell industry. Hon. A. K. Maclean is chairman of the committee.

**Tungsten Market Steady.**—There has been less movement of ore of late owing to lighter offerings of the more desirable grades. Demand for wolframite is fairly active at $24 and for scheelite at $74.50, New York. Off-grade tungsten ores are limited and absorbed as offered at the usual price differential.

**More Ships Launched in U. S. Yards.**—Ten steel ships of 57,695 tons and six wooden ships of 21,500 tons were launched by American yards in the week ending May 5, the Shipping Board announced recently. Twelve steel ships of 80,180 tons were delivered to the board complete in the same period.

**To Conserve Fuel.**—In order to assist in the conservation of fuel the Grand Trunk Railway are considering the installation of a powdered fuel system in their shops at Point St. Charles. The problem has been carefully gone into by the officials, but final decision has not yet been made.

**C. P. R. Changes.**—The Canadian Pacific announces the following promotions and changes in the New Brunswick district; Mr. J. H. Boyle is appointed superintendent, Brownville division, succeeding Mr. H. J. Humphrey, transferred. Mr. C. Gribbin is appointed master mechanic, succeeding Mr. C. Kyle, transferred.

**Extending Plant.**—The Swedish Crucible Steel Co., Windsor, are building a 100 ft. extension to their foundry, and will also build a machine shop 75 x 100 feet. In the foundry extension they will install three fourteen-ton moulding machines by which the company's production of large steel castings will be very considerably increased.

**Will Rebuild Plant.**—Fire broke out in the plant of Canada Beds, Ltd., at Chesley, Ont., on April 26. A newspaper report claimed it was of incendiary origin, but the firm is not inclined to accept this view. An official said to CANADIAN MACHINERY: "We will suffer a loss, but anticipate rebuilding. We are not at the present time prepared to state what equipment we will require but will be able to give you full particulars after our adjustment is made."

**C. P. R. Promotions.**—W. E. McGill is appointed assistant superintendent, Montreal terminals division, in place of J. B. Blair, transferred. H. P. Creighton is appointed B. & B. master, with headquarters at Schreiber, vice E. T. Draper, transferred. C. A. Wheeler is appointed division master mechanic, with headquarters at Sudbury, vice T. Hambley, promoted. T. Hambley is appointed master mechanic, with headquarters at North Bay, vice C. Gribbin, transferred. J. S. Allen is appointed general foreman, locomotive erecting shop, North Bay.

**Labor Troubles.**—Three hundred moulders left their work in sixteen Toronto shops on Friday night over wage differences. Their present wage is $4.50 a day and their requested increase is to $6 a day. It is stated in connection with this strike that it may extend to Hamilton. In British Columbia the wages now being paid for this class of work is $6.25 a day. Sheet metal workers are being paid 50 cents an hour and are asking 65 cents. They are being offered, it is stated, 52½ cents. Plumbers and steamfitters working on the water front are being organized now.

**Tool Companies Merge.**—The Independent Pneumatic Tool Co., Chicago, a New Jersey corporation, and the Aurora Automatic Machinery Co., incorporated in Delaware, have been consolidated under the name of the former and have been capitalized at $3,000,000. The general

[illegible] of the company are: G. the Thor Building, 130 Scott Michigan Boulevard, Chicago. The pneumatic and electric tool plant is located at Aurora, Ill., and motor cycles and gasoline engines are manufactured at 361 West Superior Street, Chicago. John D. Hurley has been elected president.

**Lake Superior Corporation Production.**—The Lake Superior Corporation for nine months ended March 31, 1918, produced 211,452 tons of finished material, as compared with 170,076 tons for the same period in 1917. The unfilled orders on hand March 31st, 1918, approximated 392,795 tons. Steel ingot output in March was 48,000 tons. This exceeds the output of three preceding months. The company intends to bring production to around 50,000 tons a month, and to attain this is working on the construction of thirty coke ovens.

**Hamilton Industrial Prospects Good.**—Speaking of industrial prospects, C. W. Kirkpatrick, commissioner of industries, said the outlook was never brighter than at the present time, when he is carrying on negotiations with twelve different concerns which are considering Hamilton as a favorable point in which to locate branch factories. Mr. Kirkpatrick is very desirous of securing a small factory building with a floor space of not less than 12,000 square feet, for an American concern which wants to locate in this city. Such a building must be adapted for light machinery and foundry work.

**Patents Issued.**—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—Joseph G. Rubino, talking machine cabinet; Andrew F. Small, fastening means for wall boards; Henri H. Vosburgh, turnbuckle; William Wilkie, machine for turning down the edge of cloth of wearing apparel in the process of manufacture; David Bridge & Co., Limited, friction clutch; Mead, McLean & Co., Limited, ventilators for vehicles and the like; Borden's Condensed Milk Co., dried milk and its manufacture; Harry E. Day, gearing; Thomas Gill, gear boxes for automobiles and other vehicles; Earl D. Ryckman, stump extractor.

**Shipments of Coal to Canada Restricted.**—Plans for the restriction of the movement of anthracite coal from the United States to Canada during the present year have been formulated by the United States Fuel Administration in co-operation with the Fuel Controller of Canada. A representative of the former attended a recent conference of representatives of coal operators, coal miners and railways in Canada, at which this problem was discussed. The conference reached an agreement as to the movement of anthracite coal into Canada, embracing the following: Anthracite coal supplies to points in Western Canada will be materially restricted during the present coal year. No American anthracite will be available for shipment to points west of Winnipeg.

# TENDERS

**Edmonton, Alta.**—Tenders will be received up to June 1st next for the supply of automobile number plates for the Province of Alberta during the year 1919. Specifications may be obtained on application to the Deputy Provincial Secretary, Edmonton, Alberta.

**Quebec, Que.**—Tenders for storage dam at river St. Anne (of Beaupre) will be received at the office of the Quebec Streams Commission, Room 125, Parliament Buildings, Quebec, until Tuesday, May 21, 1918. Plans and specifications can be seen at the said office or at the Quebec Streams Commission's office, Montreal.

**Ottawa, Ont.**—Tenders will be received until Friday, May 10, 1918, for the roofing and sheet metal work for Military Orthopedic Hospital, Christie street, Toronto, Ont. Plans and forms of contract can be seen and specifications and forms of tender obtained at the offices of the chief architect, Department of Public Works, Ottawa, and the clerk of works, Postal Station "F," Toronto, Ont.

**Dundas, Ont.**—Tenders will be received up till May 14, 1918, for reinforced concrete sedimentation basin and rapid sand filter as follows:—A. Bulk tender for basin and building of reinforced concrete and hollow tile; B. Filter equipment. Plans and specifications may be seen at the office of E. H. Darling, consulting engineer, 604 Spectator Building, Hamilton, Ont., or at the office of the Commission, Dundas, Ont.

**Ottawa, Ont.**—Tenders will be received until May 21, 1918, for the "Iron Stairwork" required in the reconstruction of the Parliament buildings. All tenders to be based on the supplying, execution, erection and completion; together with the furnishing of all tools, appliances, labor, etc., as required and described by the plans and specifications for "Iron Stairwork." Plans and specifications and any other information required can be obtained at the office of the general contractor, P. Lyall & Sons Construction Co., Ottawa.

**Ottawa, Ont.**—Tenders will be received until May 21, 1918, for the plate glass and leaded glazing required in the rolled steel casements of the exterior of the Parliament Buildings. All tenders to be based on the execution, completion and delivery on the site; together with the furnishing of all material, tools, appliances, labor, etc., for the work as required and described by the plans and specifications and in conformity with the samples submitted, for—(A) Glazing exterior casement frames; (B) Exterior leaded glazing. Separate tenders will be submitted for "A" and "B." Plans, specifications and any other information required can be obtained at the office of the general contractor, P. Lyall & Sons Construction Co., Ottawa.

# MARINE

**Vancouver.**—The Way Cayuse, a 2,500 ton wooden ship, was launched successfully at North Vancouver, the third of

its kind to take the water from the Lyall shipyards.

**Coke Export Licensed from U. S.**—A Washington dispatch states that Fuel Administrator Garfield has placed coke under license for export to foreign countries.

**Sarnia, Ont.**—The steamer Royalite, which arrived at Sarnia with a cargo of oil last Saturday, is being lightered before proceeding to Welland. She encountered heavy ice on her trip down and is leaking.

**Fort William.**—Captain Jordan, master of the steamer Franz, the first of the lake carriers to make Fort William harbor since the opening of navigation, was invited to the Kam. Club, where he was presented on behalf of the Fort William Board of Trade with the customary high silk hat, by W. F. Hogarth, chairman of the harbor committee of the board.

**Montreal, Que.**—The Canada Steamship Lines' vessel, Calgarian, 1,300 tons, has arrived light from Toronto and will proceed to the Montreal drydock for repairs prior to being placed into commission for other work. When ready for sea the Calgarian will in all probability leave for an Atlantic port to start upon her new duties.

**The Canadian Bridge Co.**, Walkerville, Ont., announces the appointment of John W. Seens as sales manager with offices in the New Birks Building, Montreal, effective May 1, 1918. Mr. Seens was for the past seven years manager of the Structural Steel Co. of Montreal. Joseph Labelle, formerly designing engineer of the Structural Steel Co., has been retained as sales manager in the Montreal office of the Canadian Bridge Co.

**Halifax, N.S.**—The Dominion Government steamer Stanley, reported in distress north-east of East Point, P.E.I., while en route to the Magdalen Islands from Louisburg, C.B., is still drifting helplessly in the ice. A wireless message from the steamer last Friday night to the Marine and Fisheries Department here reported that she was then only ten miles north-west of Cape St. Lawrence, C.B. The Stanley reported that she had effected temporary repairs to her rudder, but that the ice was so closely packed that she could make no headway.

**Demand for Tractors Was Quite Heavy.**—The Dominion Government has received orders for every one of the thousand tractors ordered from the Ford Company on behalf of Canadian farmers, and is taking no further applications. The Ontario Government, which took 200 of the Dominion's tractors, still has from 79 to 80 available. Farmers who want a tractor are advised to get in their orders since with the press of contracts with various State Governments the Ford Company will not be able to fill orders from private individuals for some time.

**Standardize Wages in Railway Shops.**—Conferences between a committee representative of all the railway shop trades of Canada and a committee representative of all the Canadian rail-

# Hydro-Electric Grave-Digging in Progress

FOR every Canadian interested in the principles of public ownership that pays there is a regular searchlight on the subject in THE FINANCIAL POST of May 4th. On page 10 appears an editorial and a leading article which give financial facts, and business-like principles so intimately connected with the ultimate success of the Hydro that not even the most decided critic of public ownership as expressed in the present management of Hydro-Electric affairs in Ontario can fail to find in them food for thought.

## Burial of Hydro Hopes

In the [illegible] account rendered from the pen by City Auditor H. T. Jamieson, of St. Catharines, there are warnings which cannot be neglected. They point to the [illegible] Hydro methods of financing and accounting at present [illegible] to the very spade and pick-axe strokes by which the Hydro is digging its own grave as fast as human [illegible] Whether you are a supporter of Sir Adam Beck or not [illegible] these articles. They are intensely important to all Ontario to-day, and to all Canada as far as principles of public [illegible] are concerned. Remember they appear in THE FINANCIAL POST of May 4th, and with them THE POST contains the most [illegible] of business news under such headings as these:

Canadian Trade Increased Bank Credits in March

Provincial Commission Forestal's Courts Re Niagara Franchise.

Mystery as to What Britain is Doing With Gold.

Reconstruction of Cabinet is Ottawa Gossip.

Looks like Three Hundred Million Bushels Export Wheat.

Iron Enough for Twenty-five Years' Supply in B.C. Ores.

Claims of British Columbia as to C.N.R. Voiced by Premier

Underlying Causes of Movement in New York Funds.

April was a Good Month in Toronto Realty Business.

German Banks Amalgamate in Preparation For After War.

Bond Market Has Been Pretty Well Cleared of Issues.

Edmonton Taking Steps to Meet Its Maturing Bonds.

Montreal Asks One Million From Quebec Province.

Fire Insurance Commission Takes Up Fire Prevention.

Jitneys to be Abolished in Winnipeg.

Lord Shaughnessy's Report on Canadian Pacific Railway

Organizing for Victories to Follow the War.

These [illegible] indicate some of the principal subjects of importance to Canadian business men and investors which you will find ably dealt with both as to news facts and comment in THE FINANCIAL POST of May 4th. Remember, THE POST is the business newspaper of Canada with not only a high standard staff of its own, but with the specialized attention and assistance of [illegible] newspaper editors also devoted to making [illegible] alert man of affairs. For Three Dollars a year you can have THE POST every week. Just fill up this coupon.

[illegible] trades and local in Montreal last week with a view to standardizing wages throughout the country. The various shop trades recently determined on a closer organization to obviate the overlapping of effort perennially expended in various parts of the country with the end in view, and as a result they formed Division No. 4 of the American Federation of Labor, Railway Department. Then they appointed a committee of twelve from that division to negotiate with a joint committee from all the roads wherever changes are desired in the wage schedule now existing and in the present working conditions. Fifty thousand men are involved in the negotiations.

**Launchings from U. S. Shipyards This Year.** Exact figures on the progress of the merchant shipbuilding program in the United States this year were disclosed last Friday for the first time. They show that under direction of the Shipping Board there have been launched 236 steel and wooden vessels, with an aggregate tonnage of 1,440,622. There now are operating 157 shipyards with 753 ways in use. There are 398 steel ways, 332 wooden ways, either completed or under construction, four concrete ways, and 19 ways devoted to naval work. The launchings of steel ships include 18 vessels with a total tonnage of 136,250, constructed under Government contracts, and 183 with an aggregate tonnage of 1,195,887, obtained by requisition. The grand total of contract and requisitioned ships already launched is 1,332,127 tons. Already delivered are 138 steel vessels, with a total tonnage of 977,371. Wooden ships launched number 35, with an approximate tonnage of 108,500.

## BUILDINGS

**Toronto, Ont.**—City Architect Pearse has issued a building permit to M. Granatstein for a four-storey brick and reinforced concrete warehouse at 488 Wellington street west. The building will cost $50,000.

## CONTRACTS

**Vancouver, B.C.**—The Davies Construction Co. have the general contract for the erection of a $11,500 car shop for the C.P.R.

## RAILWAYS

**Toronto, Ont.**—The Hydro-Electric Power Commission has been granted permission by the Ontario Railway and Municipal Board to construct a temporary railway over certain roads in Stamford Township in order to provide an outlet for material taken out in the excavation of the new Chippewa power canal. The road will be taken up when the work is completed.

**Brantford, Ont.**—Notice has been received here by the Board of Trade that the Dominion Railway Board will meet in Brantford to consider the application of local manufacturers for free interswitching between the three railways—G. T. R., T., H. and B., and C. P. R. At present an order of the Dominion Board is effective that where a railway has a switch into a factory, the railway in question has priority in the matter of routing outgoing freight, and the application of this city is for the rescinding of the order

## WOODWORKING

**John Island, Que.**—The saw mill owned by the Multhrop Lumber Co. was recently destroyed by fire.

**Grandmere, Que.**—The Laurentide Co's saw mill was destroyed by fire recently, the loss being estimated at $20,000. The company will rebuild.

**Port Arthur, Ont.**—J. Stirrett & Sons is making preparations for the erection of a sawmill to cost, including machinery, etc., approximately $60,000.

### JUST LIKE YOUR WORK

(Continued from page 497)

settle by next day. I told him plain I'd cut the belts and take out his machinery if he failed. He wanted to give security. I told him we didn't want security. I was there to get the machinery or the money. I knew what he had in the way of assets and showed what we were prepared to do. Well, to make a long story short, we made an agreement for the time. Later he sold, but I went to repossess the place. As soon as our men were ready to go ahead the mill man appeared with a gun. He didn't have much to say, simply, 'The first man who lays a hand on this mill will be shot.' It was up to me, so I said 'I'll be the first man, now shoot.' It didn't do any good. The rest of the boys didn't like the looks of the gun and quit. Later he sold the mill and I garnisheed the payment. I met him in town shortly after. 'Well, you beat me to it in the end,' he said. We shook hands and at his suggestion and expense we went out and had dinner on top of it. We parted very good friends."

**The "Promoter" Type**

Mr. Cronk is not in love with the promoter. "I remember one chap, a German. He came in here and bought about $8,000 worth of machinery, paying a good sum down. He put that plant in a Saskatchewan town and organized a million dollar wood-turning business. Taking it into another province put a few kinks in the usual run of liens on the plant, and we had quite a lot of trouble getting that squared away. In that case I was up against the Saskatchewan Government and several corporations and loan agencies. It was a big squabble, but we got the machinery."

Mr. Cronk is well known in the machinery trade. As the picture on this page suggests, he's fond of flowers. The other shows him on the load near Monteith.

**J. G. Reid**, assistant superintendent of dredging of the Montreal Harbor has just completed his 24th year in the service of the Montreal Harbor Commissioners.

## THE PITTSBURG MARKET LETTER

(Continued from page 502.)

are taking more interest in the distribution of the so-called "commercial" steel, recognizing clearly that some of it is indirectly very helpful towards winning the war. At one time it was contemplated to take over formally the distribution of all commercial steel. This proposition has been tabled, with the understanding that the mills themselves distribute such steel as may be left, in places where it will do the most good. Without a formal order, the producers have been informed that they should set first in the distribution of commercial steel two classes: (1) Steel involving oil development and transportation; (2) Steel involved in agriculture. Other classes of consumption the steel producers are to serve according to their own judgment.

### The Market

In the circumstances the finished steel market has become a particularly narrow one. Transactions are of course altogether exceptional, when so little of the commercial steel on books is being shipped. There is no very great buying pressure upon the market, however, because consumers as a rule are much more interested in securing deliveries against orders already on books than in placing additional orders. In pig iron there is a moderate amount of business, in point of number of orders, but the tonnage is small, and most of the orders are for Government account.

### Production

Production has been increasing slightly, but only very slightly. Taking a few weeks together there is an increase, and production at the moment is probably nearer 90 per cent. of capacity than 85 per cent., which was approximately the average in March. The Carnegie Steel Company has put on two additional blast furnaces, giving it 51 in operation of a total of 59, its pig iron production being now about 90 per cent. of capacity. Other interests are operating at higher and lower rates than this.

Lanco Balata Belting
is now one of the most expensive belts on the market.
When the cost of raw material increased the price of this belt to what it is today we were a little afraid that it would result in a decrease of our sales. We have been very agreeably disappointed the sales have not dropped off.
There are cheaper belts on the market that will give a good service but not for a long time. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the plies tightly together, is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that, as far as we know, has never been equalled by any other gum. The duck is of course stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions, except those of heat, it will give a length of service that makes its price worth while.

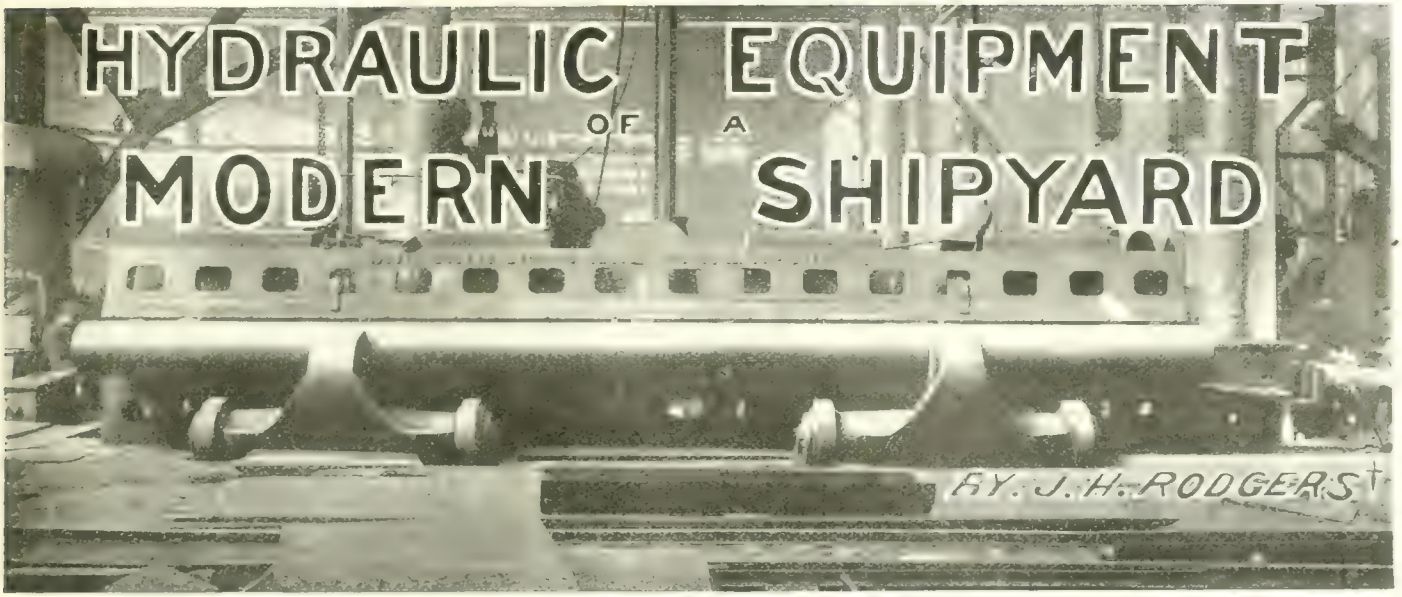
# HYDRAULIC EQUIPMENT OF A MODERN SHIPYARD



*Through the courtesy of a prominent Canadian shipbuilding company we are enabled to present the accompanying article which illustrates modern practice in a fully equipped plant.*

MODERN steel ship construction would be practically impossible without the aid of hydraulic equipment. The nature of the enterprise involves the forming and bending of heavy steel plates for the hull and the framework that would be difficult to accomplish by any other method. The developments that have taken place in this country during the past two years, and more particularly in the last twelve months, have resulted in the establishment of many new shipyards, but owing to the great difficulty in obtaining ship plates, a great number of these yards are constructing wooden vessels. In view of later expansion when the necessary plates are available, it is of interest to study the class of hydraulic machinery installed by one of the large Canadian shipyards.

Weather conditions in Canada are not particularly favorable for the successful maintenance of such equipment, as it is generally located in large sheds or buildings which are difficult to heat during the winter months. Destruction of hydraulic appliances through the agency of frost must be guarded against, especially in northern climates, where the possibilities of freezing are much greater, owing to the frequent and often sudden changes of temperature and atmospheric conditions. This plant, although situated on the shores of the St. Lawrence River, has experienced little difficulty in this connection, due largely to the efficient piping installations and its method of delivery from the pumps in the engine room to the various departments.

From the accumulator, located in the engine room, the piping is carried through a spacious tunnel well below the ground level, the top of the tunnel being about six feet below the surface. This tunnel also contains all electrical conduits, water pipes, steam pipes, etc., which assist in maintaining a uniform temperature that prevents the possibility of frost. The total length of the tunnel is nearly 3,000 feet, and it extends from the power plant to the iron workers' shed, and thence alongside one of the quay walls. From the main tunnel the piping is distributed to the various buildings and to the different machines. This system of delivering the water from the pumps to the presses has been the chief help in avoiding trouble from frost. During the past winter, however, a slight accident was experienced on the horizontal bulldozer, shown in Fig. 1, when the flange of the return cylinder was broken off, through the freezing of the water and the subsequent expansion. This indicates the necessity of always draining the water from hydraulic equipment whenever it is out of service, and also the precaution that must be exercised to guard against low temperatures where such machinery is used.

### Portable Hydraulic Forming Press

One of the disadvantages of hydraulic equipment is that it is not very suitable for portable use owing to the special facilities that would be required for such purposes, so that in few instances will it be found that appliances are adapted for service other than in a permanent position in the shop, where the work can be conveniently brought to the machine for the necessary operations. However, occasions sometimes arise where it is almost impossible to accomplish certain operations unless the machine can be transferred to different locations on the work, where the same is held in a fixed position while one or more bends are being formed. This condition applies to the shaping of many pieces in connection with the angle irons that constitute certain portions of a ship's framework. By the use of a small portable press for this purpose it is much easier to work to the template, which can be more conveniently handled when it is not required to move the piece being formed.

For efficient work of this character it is necessary to have suitable equipment; on the discharge end of the furnace, where the work is heated, it is the general practice to have a considerable space fitted with heavy cast iron floor

†Associate Editor Canadian Machinery

FIG. 1. HORIZONTAL BULLDOZER

press, the top surface of which is made as level as possible. These plates are provided with a large number of cored holes into which are placed the steel pins that act as fulcrums for the bending operations, and also a heel for taking the thrust of the hydraulic ram.

In Fig. 2 is shown one of the few hydraulic units adapted for portable service. In the operation of this press it is necessary to utilize two lengths of hose, one for the supply and the other for the discharge. For moving from one location to another the appliance is provided with a pair of handles, the lower ends of which are connected to a pair of wheels in such a manner that the cylinder is raised from the floor when the handles are pressed downwards, thus facilitating the movement of the machine to another position. The ram of this particular press is 4 inches in diameter and the working pressure is 1,500 lbs. per sq. inch.

The chief difficulty experienced in the operation of portable hydraulic equipment is the inability to get flexible connections that will stand up to the continual strain of the high pressure required. The pressure itself is not the most serious factor, but if particular care is not exercised in moving the machine the liability of kinking the hose, first in one direction and then in the other, soon destroys its usefulness, as cracks frequently develop and prevent further use for effective work. The reinforced hose used in this plant is principally of English manufacture, as others have not given very good results. Even the best, however, will have a short life unless great precaution is taken to protect the hose from injury.

### Hydraulic Press With Plate Frame

A special design of press is shown in Fig. 3, where the frame is composed of steel plates, I beams and angle irons. The cast iron cylinders are supported between the overhanging arm with their axis in a vertical position, the main cylinder being 9 ins. in diameter and the return cylinder 4 ins. This press can be used for a large variety of light work, owing to the double arrangement of the working of cylinders. It is generally used for the making and trimming of small forgings. Presses built after this pattern are not as satisfactory as those constructed of cast iron, owing to the greater elasticity of the metal.

### Vertical Plate Rolls

Forming the plates for the cylindrical portions of marine boilers is one of the chief details in connection with the work of a shipbuilding plant. In many establishments, particularly those of the smaller type where the plates are of the lighter sizes, the three-roll horizontal system is extensively used. In this plant the heavy plates for the high pressure boilers are formed in the large vertical plate roll shown in Fig. 4, manufactured by Hugh Smith and Company of Glasgow. With the three-roll type the bend is made by the action of the rolls in motion, forcing the plate against the third or shaping roll. In the machine here illustrated the bend is accomplished by the application of pressure while the plate is held stationary, this action being repeated at regular intervals as the plate is revolved intermittently, by the movement of the large main roll.

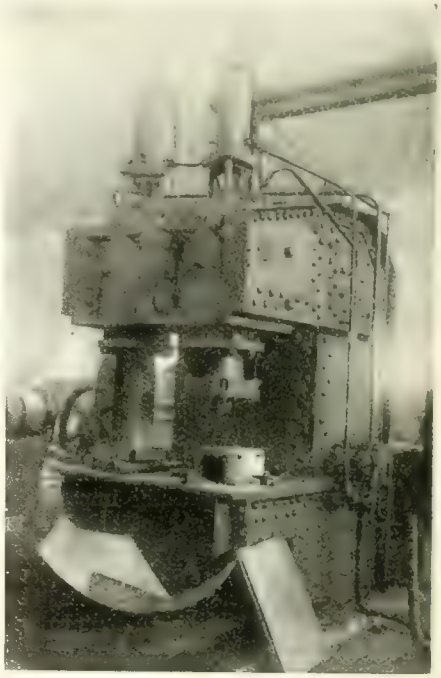


FIG. 3. 60-TON HYDRAULIC PRESS WITH PLATE FRAME.

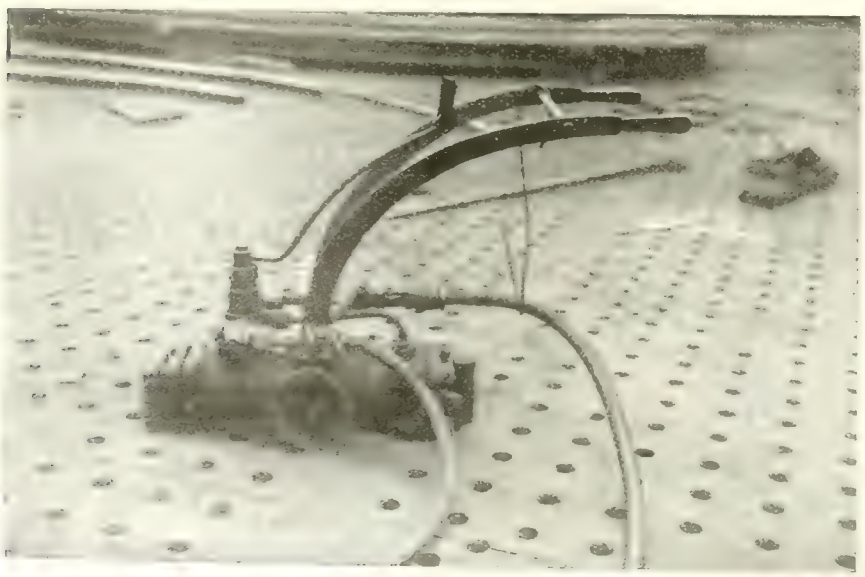

FIG. 2. SMALL PORTABLE HYDRAULIC UNIT.

The machine can be operated at will or automatically, as desired, and the movement can be obtained in either direction. When the plate is first placed in position in the machine, the small rolls A A A that are carried in the forked end of the piston connected to the ram of the small hydraulic cylinders contained in the main cross beam, are moved back to permit the insertion of the plate

between the small rolls and the main roll B. The three small rolls A are for the purpose of retaining the plate in constant contact with the main roll, and maintain it in a parallel position while it is being revolved for the following impression. The diameter of these small cylinders is about 3 ins., so that with an initial pressure of 1,500 lbs. per sq. inch the power exerted against each of the three rolls will be about 10,000 lbs. When in the desired position, the movement of the large roll—which is obtained through a system of gearing below the floor—is stopped, so that the bending pressure is applied when the plate is at rest.

The front face of the cross beam C is formed of two long narrow machined strips on either side of the central recess, into which the roll B enters when the cross-head C is forced outwards. This movement is obtained by the action of the toggle F at the top and a similar one (not shown) located below the level of the floor. One end of these toggles is secured to the movable cross-beam C, while the other end is pivoted to the fixed frame member G. The knuckles are connected to the links extending from either end of the operating ram, the cross-head of which is seen at E; the hydraulic cylinders D being located about midway of the height and supported on the central tie rods. The automatic ratchet mechanism is shown at H, and the main control handle at I. When the auxiliary handle is locked in the position shown, the machine will operate automatically during the period desired. When the end of the plate has been reached the reverse is set by hand and the machine operated automatically in the opposite direction. On the heavy plates several reversals are necessary before the required operation is completed. This machine has a capacity for plates about 10 ft. wide and 1½ in. thick.

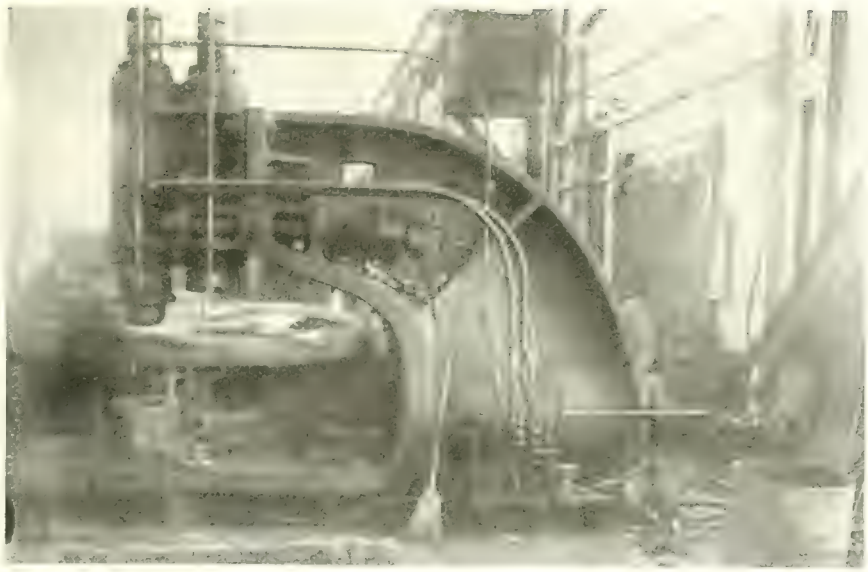

FIG. 5 FOUR-CYLINDER FLANGING PRESS

### Four-Cylinder Flanging Press

A very interesting design of hydraulic press is illustrated in Fig. 5. This is the single frame type and is provided with four rams; two in the upper portion of the overhanging arm, parallel and adjacent to one another; one in a horizontal position at the junction of the arm and the base; and the fourth in a vertical position in the base, in line with the outer of the top two. The arrangement of these four cylinders is such that almost any operation of a flanging, forming, or bending nature can be readily performed. When flanging, the forward of the upper two rams is used as a clamp, while the inner one is bending the flange. The horizontal ram is then used for finishing the piece to the desired shape of the forming block, the latter being bolted to the bed of the press. Each ram can be operated independently, the control levers being shown in the right foreground. For such operations as fire hole or man hole forming, special dies are constructed so that the impression is made at one setting of the dies. Large furnaces are located nearby for the heating of the materials.

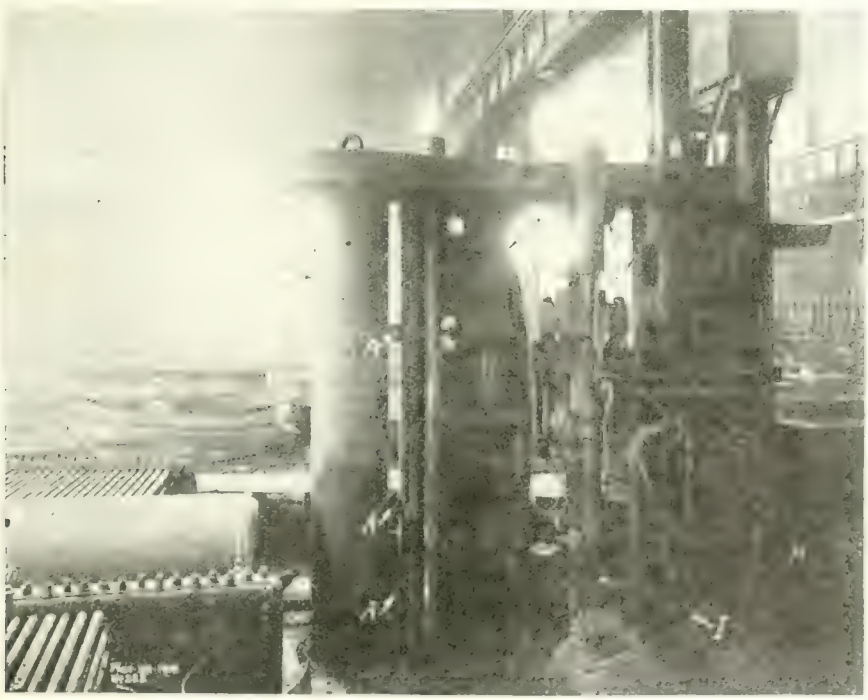

FIG. 4 VERTICAL BOILER PLATE ROLLS

### Large Hydraulic Gap Riveter

In the manufacture of boilers and the construction of steel vessels the uniting of the various parts is mostly accomplished by means of riveted joints, with subsequent caulking of the seams to make them perfectly steam or water tight. Hand riveting is fast becoming a lost art, as power appliances are now extensively used for this purpose. Pneumatic tools are probably recognized as being of greater service than those operated by hydraulic pressure; this, however, is due to the portable character of the air operated tools and the adaptability to conditions, where it would be impossible to use the hydraulic equipment, rather than the inefficiency of the latter, as in many respects the steady pressure of the hydraulic riveter will accomplish much better results than the rapid fire of the pneumatic tool.

For fabrication work the hydraulic riveter is generally given an important place in boiler shop and shipyard equipment, although necessity demands that the air riveter be utilized for erection purposes. Another feature that restricts the hydraulic machine to certain limits is the fact that the resistance of the operating pressure must be taken by the same frame that supports the hydraulic cylinder. It will therefore be readily seen that the effective use of the hydraulic riveter is confined within certain limits, whereas the air-operated tool can even be used to good advantage where it would be impossible to use the hand hammer.

In Fig. 6 is illustrated a large Southwark 12-foot gap riveter, used for the construction of marine boiler shells. The

the ram that carries the rivet set is sup-

**Keel Plate Bending Machine**

An interesting machine, both as regards its dimensions and its operation, is that of the keel plate bending machine shown in Fig. 8. The overall length of this machine is nearly 38 ft. and its total

The clamping of the stock is accomplished by hydraulic pressure from a 6 in. dia. cylinder located at the extreme right of the machine. The axis of this cylinder is set at an angle of 6 deg. with the horizontal to coincide with the taper

FIG. 6 [illegible] GAP HORIZONTAL RIVETER.

FIG. 7 300-TON HYDRAULIC JOGGLER.

with the set in the anvil. The cylinder has a diameter of 9 ins., which gives a compression pressure on the rivet of about 45 tons. A platform is provided for the convenience of the operator. An advantage that the hydraulic method of riveting has over the pneumatic system is that the applied pressure has a greater tendency to spread the rivet in the hole, a factor that adds to the stability of the work.

**Lambie's Hydraulic Joggler**

Joggling of bars and angle irons is a frequent operation in connection with steel ship construction. For this purpose it is necessary to provide powerful machines, owing to the sharp offset required. Fig. 7 shows a Lambie's hydraulic joggler adapted for this operation. This press is of special heavy design, the operating cylinder having a diameter of 24 ins., providing a pressure, when fully loaded, of 300 tons. The return cylinders, 6 ins., dia., are located on either side of the main cylinder, and are used for discharging the water from the central cylinder and elevating the ram after the operation has been performed. The press is provided with special dies for the rapid handling of the work; these dies are so constructed that they can be adjusted laterally for the different thicknesses of metal.

weight is approximately 90 tons. The main braking beam, over which the stock is bent, is in two sections and is supported—or suspended—from four massive arms extending up from the back of the machine. These are of the box type to reduce the weight and yet provide ample strength and rigidity for the heavy duty required. The forming roll, made of forged steel, has a diameter of 17 ins. and a length of 30 ft., the weight of the roll being about 12 tons. The roll is freely supported at a distance of about ¼ of its total length from each end in the bearings of the two swinging arms, the lower end of each arm being attached to the ram of a hydraulic cylinder, which is located below the floor level. The diameter of each cylinder is 18 ins., so that a total pressure of 180 tons can be exerted in the bending of the work, with the exception of that required to raise the roll and its supports. The roll is not fixed in its bearings, so that in the process of forming the work the shaft has a tendency to roll upon the material, thus eliminating the friction that would otherwise be present.

To guide the swinging arms in their proper path and also maintain them in a parallel position, two links are provided on either arm, the inner end being secured to lugs on the machine base.

of the wedge on the clamping beam. The upper edge of this beam is parallel with the under face of the brake beam, and the lower surface is divided into four equal steps or wedges, having a taper of about 1 in. per ft. The two main cylinders can be operated jointly or independently as desired, so that tapered work may be easily accomplished. This machine, while primarily designed and intended for the bending of keel plates, can be adapted to a variety of purposes in connection with steel ship construction.

**250-Ton Press for Large Work**

Of the many designs of hydraulic presses, none is more adaptable to such a wide range of operations than that shown in Fig. 9. This machine is especially suited to the forming of large plates into shapes that would be very difficult to obtain in any other manner. By the use of various blocks, either of wood or iron, any desired shape can be readily attained, the workmen in time becoming very expert in its manipulation. The base of the machine, with the operating cylinders, is located below the floor level, and extending upwards are the four main corner shafts for supporting the upper head. The four corner screws are threaded for over half their length for adjusting the position of the top head.

The screws are 8 ins. in diameter, and 2½ threads per in., the nuts being 6 ins. thick. These nuts take the entire thrust of the hydraulic pressure, minus the weight of the part supported by the ram together with that of the top head. The lower table is on a level with the shop floor so that it is comparatively easy to move the work to and from the machine. The operating cylinders are four in number, the diameter of the main cylinder being 21¾ ins.; the internal cylinder 14 ins., the push up cylinders 7½ ins., and the clamping or vising cylinders, 6 ins. The control levers are shown to the extreme left.

## MINING SOCIETY OF NOVA SCOTIA PRESIDENTIAL ADDRESS

At the recent annual meeting of the Mining Institute of Nova Scotia (May 1 and 2), the presidential address was delivered by D. H. McDougall, general manager of the Dominion Steel Corporation, Sydney, N.S., who said:

On the occasion of our last meeting I made reference to the part played in this war by coal, and the subsequent course of events has given the general public and ourselves a very lively appreciation of the value of our domestic fuel supplies. We have realized through actual trial and experience the bearing of fuel supply upon our national independence. A combination of labor shortage, inadequate transportation facilities and unprecedently severe weather conditions during the past winter caused a fuel crisis in the United States which, but for swift and drastic action on the part of the United States Government, would have brought about a national catastrophe, in which we also should have been involved.

We have realized that no nation can stand alone unless it possesses an adequate fuel supply within its own borders. Fortunately for Canada, the republic to the south of us is our ally and companion in arms, and Canada has received most generous consideration from the United States in this matter of fuel supply.

Recently in Ottawa a representative of the Fuel Administrator of the United States told the assembled coal miners, operators, and transportation men of Canada that Canada would receive the same treatment from Dr. Garfield as though it were part of the United States itself. We were told that in the distribution of the available coal supply of the United States the boundary line between the two nations would be absolutely ignored, and that so far as the distribution of this most vital munition of war was concerned North America would be looked upon as being one nation with one common aim.

### Fuel Supply and Transportation

We have learned the intimate connection between fuel supply and transportation facilities. In this country of vast distances they are in fact practically indistinguishable one from the other. The problem of the utilization of the great bituminous and lignite fields of the Canadian West—as was abundantly demonstrated during the recent Fuel Conference at Ottawa—is altogether one of transportation.

I may remind you that the coalfields of Nova Scotia remained undeveloped, and the industry, which we so largely represent, did not emerge from its small beginnings until the transportation problem was solved, and the St. Lawrence market was opened to Nova Scotian coal by the provision of modern coal freighting vessels and of modern loading and discharging plants.

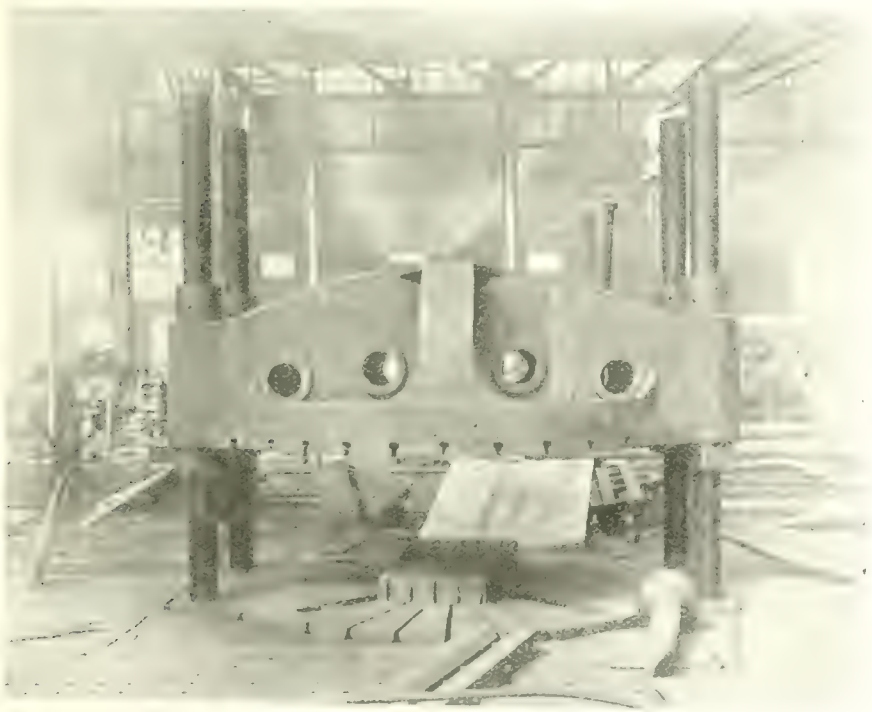

FIG. [illegible]-TON HYDRAULIC PRESS

At the present time the enormous increase in the percentage of coal consumed within the Province of Nova Scotia itself, accompanied by declining outputs, has obscured the present importance of transportation in our own particular case, but this problem will revive and will face us in greater intensity whenever we seek to regain the St. Lawrence market as an outlet for Nova Scotian coal.

We have further learned that the value of fuel and all questions of comparative excellence of fuels become considerations of a secondary character during times of fuel scarcity. We are learning to make the best of our own natural resources, and when fuel such as anthracite, possessing the desirable features of smokelessness and high calorific value, cannot be obtained, we must perforce turn our attention to the utilization of such fuels as peat, lignite, and even wood.

The Fuel Controller of Canada has announced that it is extremely unlikely that United States anthracite will be available next winter in the prairie territory west of Winnipeg, which means that bituminous coal and lignites will have to be used as substitutes.

It is not an unmixed evil for a people so virile and enterprising as our own people to be thrown back on their resources because it naturally leads to development and progress and probably the discovery of unsuspected excellences both in our natural resources and in our ability to make the best of them.

I may, in passing, point out that the shortage of anthracite is not a mere phase originating in present conditions. No country in the world, unless perhaps it is China, has been so favored in the possession of anthracite resources as the United States, but that the anthracite fields there are approaching a period of comparative exhaustion is evidenced by the fact that very thin seams of anthracite are to-day being worked, seams which in the past it would not have been deemed worth while to operate.

Another thing that we are learning is the intrinsic value of coal itself. Probably in regard to no basic raw material has there existed so widespread a misconception as in the case of coal. This misconception has not been confined to the general public, but it has extended to those whose daily business is the production and sale of coal.

The ultimate factors entering into the cost of coal have not been fully understood, and, without entering into detail, it may be briefly stated that coal has in the past—both in Canada and in the United States—been sold at prices below the actual cost of production, when such cost is considered over the whole life of any given coalfield. Further, it may be stated that the material value of coal itself has been underestimated, and perhaps no raw material has been so wastefully and unscientifically consumed in the past.

### Coal Supply and Demand

We are learning that the price of coal is not a deciding factor in days of fuel

[illegible] to produce.

[illegible] sharpest lesson in this connection. No small part of the barely averted catas[illegible] was due to the arbitrary fixing of coal prices in the summer of 1917. Any action in the fixing of prices which ignores the essential factor of production and does not simultaneously with the restriction of prices provide for the stimulation of [illegible] its own object. In the case of a raw material of such fundamental and vital importance as coal all government action should have as its first and guiding motive the increase of production.

Increase of coal production does not necessarily mean the opening of new mines, but rather the reverse. There has been throughout North America a general reduction in the working force at the collieries. In Nova Scotia this reduction of workmen has largely concentrated upon the actual miners and producers of coal as would naturally happen, because the producing class at a colliery—by a process of natural selection—includes the men most fitted by physique and mentality for military service. This withdrawal of the most efficient members of the working forces has not been peculiar to Nova Scotia, but is a noticeable feature throughout all the coalfields of North America.

Under these circumstances of labor shortage, of a selected character, the obvious remedy for the unbalanced conditions which it has brought about is the concentration of the remaining workmen in the collieries best equipped to give the greatest production of coal. The most noteworthy feature of the existing labor situation at the collieries is the inefficiency of operation brought about by the unbalancing of the forces referred to, and concentration is the remedy.

Not only is concentration desirable from the point of view of productive efficiency at the collieries, but it is also necessary to conserve the transportation factor. The fewer the points from which transportation is required and the greater the tonnage which can be moved from these points the less will be the call upon the motive power of the railways and upon shipping.

In view of the insistent calls of the army for more and still more men, it appears quite hopeless to look for any large increase of coal production arising from the provision of additional employees, and, as in the case of the fuel itself, we must make the best of the man power we have.

The coal operators are fully alive to the necessity of increasing production where it can be achieved by the use of mechanical devices, and the labor shortage has already brought forth mechanical devices which will play an increasingly important part in the future development of the coal industry. Unfortunately, this avenue of possible increase of coal production is restricted by the difficulty of obtaining delivery of machinery, so for the present the only way by which coal production can be stimulated is that every man employed in the industry—no matter what his position—shall work to the full extent of his ability.

Our chief incentive to hard work [illegible] and here you will pardon me if I repeat my statement of last year—that, "no single department of the machinery of modern warfare can move or act without coal." Those of us who help in one way or another in the production of coal are privileged in that we are able by our personal endeavors to help or hinder in the prosecution of the war. In view of the critical condition of military affairs at a time when we are approaching the end of the fourth year of the struggle, I believe I voice the feelings of us all when I say that we need no further spur.

## ACID-RESISTING IRON

FOR many years chemists and metallurgists have been seeking some form of metal which could be adapted for the requirements of the chemical industry for the purpose of resisting the corrosive action of acids, but it is only in comparatively recent years that there has become available acid-resisting iron suitable for large chemical plants.

It has long since been proven in the laboratory that a pure form of iron could be rendered resistant to either sulphuric or nitric acid by the addition of a suitable proportion of silicon, chromium or other elements, but according to S. J. Tungay who discussed the matter recently before the Society of Chemical Industry in London, Eng., the development and application of such metals upon an industrial and commercial basis was not approached until some twenty years ago.

### Foreign Efforts

In Paris, Jouvre successfully made small castings and in Germany "neutraleisen," so-called, was produced by more than one metallurgical house for producing castings to withstand nitric or sulphuric acids, but the firms which took it up did not meet with commercial success. In more recent years the development of the electric furnace had proved a valuable aid in the satisfactory commercial production of such alloys as ferro-silicon and ferro-chromium. Kowalke, in America, had made considerable research, and his tests showed that silicon present in a lesser quantity than 12 per cent. did not promote satisfactory resistance to corrosion, whilst, when it reached 19 per cent. or more, the acid resisting quality of the alloy again fell.

In addition to the serious difficulties presented by the considerable shrinkage of non-corrosive iron castings during cooling, which amounted to slightly over ¼ in. per foot in each direction, as compared with a shrinkage of about 3-32 in. per foot in the case of ordinary cast iron, the presence of graphite in any considerable quantity caused disaster. The iron must also be low in carbon and phosphorus, otherwise during the process of cooling these compounds tended to separate out and form eutectics. Some tests recently made at the Manchester School of Technology showed these eutectics to consist largely of phosphorus and silicon. These difficulties, however, had been largely overcome by suitable furnaces and by improved manipulation in mixing the metal, with the result that in present commercial practice it was found quite possible to produce a satisfactory acid resisting iron, but its application to the manufacture of large plant for the chemical industry had not until recently been completely successful.

The physical constants of acid-resisting iron compared with cast iron are as follows:

| | Cast iron. | Acid resist. iron |
|---|---|---|
| Density | 7.3 | 6.8 |
| Tensile strength (tons per sq. in.) | 9-10 | 6-7 |
| Melting point | 1150 deg. Cent. | 1200 deg. Cent. |
| Hardness | 24 | 35 |
| Heat conductivity | 10 | 8 |
| Electrical resistance | 8 | 10 |
| Contraction per foot in casting | 3-32 in. | 9-32 in. |
| Crushing 1 in. cubes | 40 tons | 34 tons |

Since the outbreak of war, acid-resisting iron has played no small part in the construction of plant for the production of propellants and high explosives. For the condensation of nitric acid, it was found to be a great boon, as plants of large capacity had to be erected rapidly at short notice, and it was found possible to instal many large nitric acid plants of this class of iron much more rapidly than would have been the case with pottery, as was more usual. In addition it was found that that acid-resisting iron possessed a much higher efficiency owing to its greater heat conductivity than earthenware. The heat transmitting power of acid resisting iron had been calculated at ten times that of stoneware or quartz, and thus the parts could be made much smaller. A condenser built of acid-resisting iron condensed a charge of nitric acid in sixteen hours, as against thirty-six hours with a similar condenser built of pottery. The metal was now being used for other purposes, including the concentration of sulphuric and other acids.

With all this success there were still difficulties to be overcome. All alloys of low silicon content, say, 10 per cent., were attacked very readily by the acids mentioned, and while acid-resisting iron which contained from 16 to 18 per cent. was satisfactory from the resistance to acid point of view, it was so very hard that it was impossible to machine it in any other way than by grinding with high-speed abrasives.

Apart from chemical plant, this iron had a wide application for anodes in connection with electro-metallurgical processes. On the outbreak of the war it was impossible to obtain magnetite anodes, since they were chiefly made in Germany, and a substitute was found in acid-resisting iron.

# An Efficient Night Force: Organization and Development

By M. H. Potter

*The following article deals with some of the troubles and difficulties likely to be encountered in the starting of a night shift. The personal equation is perhaps the greatest of these and excellent supervision is necessary for economical production.*

THE present demand for increased production has made an efficient night force a necessity with many shops. The purpose of this article is to help those who are confronted with this problem.

Three principal and closely-related factors present themselves for the consideration of the factory executive, when an extraordinary volume of product is desired, namely—facilities, labor, and time.

The first, facilities, is limited only by the ability to provide them and to use them, and here considerable flexibility of action can be taken advantage of to successfully meet new and unusual demands for production.

The second, labor, is of course limited to conditions, and by the ability of the user to supply material and facilities to keep it profitably employed, thus presenting a problem, in the handling of which more or less flexibility of action can be taken.

The third, time, has a fixed limit of twenty-four hours and can be utilized to this limit in some instances.

The degree in which each of these three items is a limiting factor in securing additional production and their relative importance to each other as restricting influences are subject to determination by analysis.

There is no profit to be gained in working additional hours per day if we greatly lower or cripple the efficiency of the workers by so doing. Likewise there is no advantage in employing workers and facilities out of balance with each other. Too many executives, especially those who are not directly in touch with the amount of work done, value the hours overtime and place a premium upon the man who maintains them.

### Proper Procedure

Methods successfully pursued to show which of these things to hit hardest to secure increased production, and to do it in a way that keeps all three balanced and in harmony, will be brought out to some extent in what follows, but the solution of this problem varies as the labor market, factory conditions, type of work and workers.

To secure the best results from the employment of a night force the surrounding conditions should receive primary attention, as the handicap of working, sleeping and eating at unusual hours is enough without having to face any other.

Power, heat and light supply, distribution and segregation should be studied, and in many instances can profitably be modified to meet and not to exceed the needs of the night force.

In some plants where power is steam-generated and electrically distributed, it is comparatively easy to make modifications, and it is often found profitable to purchase electrical power for night running rather than to run the steam plant full capacity night and day.

It pays to part line shafts, used by several departments, when only a few of the departments are operating nights, putting in small motors instead of large ones. The running of a long line shaft to take care of a few machines is frequently seen and is certainly an unnecessary waste of power.

Lighting, in particular, should be ample, as poor work and small quantity surely follow where insufficient light is provided, and, in addition to this, sufficient heat and ventilation should be supplied to keep the operators comfortable.

It must be kept in mind that where machines are running double the usual number of hours there is double the amount of chips and dirt produced and to be cared for.

Additions should be made to the stock-handling and accounting departments both in men and facilities in order that machined material will not be delayed in transit from one operation to another.

With the employment of a night crew, jig, tool and fixture equipment is a very live subject and must be given the necessary attention. Ample and immediate supplies of this equipment should be provided. Patterns should receive the same attention at such times of pressure as tools and metal patterns are frequently necessary and economical additions to equipment should not be overlooked.

### Machine Tool Depreciation

One of the dangers, incidental to night work, to be guarded against, and a point by the way which will have a direct influence on new business after the present munitions' rush diminishes, is the more rapid deterioration of machine tool equipment. It must be borne in mind that machines and tools are doing double duty and that wear and consequent misalignment and misadjustment are taking place at least twice as rapidly as usual; furthermore, at least some of the operators are temporary employees and more or less careless. Therefore miller tables, drill tables, bearings, etc., should be gone over frequently and checked and trued up when necessary so that accurate work is always possible. This precaution will remove at least one of the causes for trouble and poor workmanship customarily laid at the door of the night force.

The selection of executives and of the crew for night work has vital importance in relation to the profits derived from such work. Cases have been observed where the organization, discipline and records of a considerable night force were so lax that a few machines added to the equipment and the employment of a small portion of the best of the night men on the day shift entirely did away with the necessity of running a night force and resulted in a marked saving..

If a night force is to be employed the selection of the men comprising it should be carefully made. Good results have been attained by the selection for the principal night executives of the best men of the secondary line of day executives. If a steady, young, ambitious man with a good record behind him and good possibilities before him can be secured so much the better. For the leading night foreman and operators it is well to select some of the steadier and more reliable day men, those willing to make some sacrifices to obtain the extra compensation offered for night work.

### Lunch Room Facilities

Another feature which helps toward keeping the night workers satisfied is the serving of a lunch at cost at midnight. If possible smoking should be allowed during the night or preferably during a portion of the time.

The inspection crew should be composed of the same type of men as the leaders of the night force and final inspection left to the day inspection force.

For assembling operations it is questionable if night forces can profitably be employed, as the opportunities offered for the covering up of poor workmanship which may not be discovered until the product has passed through numerous operations and perhaps final assembly are too numerous.

Some of the incidental profits to be gained from the employment of a night force are the permanent simplification and improvement of design, appliances and methods which are sure to accompany and follow pressure work, as good suggestions are bound to come out at such times and everyone is more open to receive and act upon them than usual.

Executive talent previously more or less overshadowed is developed and proved. Space and labor requirements for a specific production receive a direct and strong illumination and old restricting ideas as to possibilities are passed by, thus permanently establishing and fixing a higher degree of efficiency. Such gains are a permanent source of revenue.

## GERMANS DAMAGED INTERNED VESSELS IN BRAZIL

When [illegible] Brazil [illegible] the number of German [illegible] was about to [illegible] With [illegible] Teutonic [illegible] the [illegible] had made considerable preparations for destruction, [illegible] the [illegible] suffering more or less serious damage, particularly to the propelling machinery, and in some cases [illegible] had to be made, while in others only portions of the cylinders had been destroyed. Commenting on the [illegible] of the work done by the German engineers as reported by correspondents, "Engineering" [illegible] case of two dam-

aged cylinders at least 8,000 holes must have been drilled transversely and vertically through the cylinders in order to effect complete destruction. Several of the vessels were taken over by the Brazilian Ministry of Marine and others by the Lloyd Braziliero Company. In the early part of 1917 the Brazilian Government invited Vickers, Limited, who had placed their experience at their disposal, to send an engineering technical officer to Brazil to survey the damage to the machinery and carry out the necessary steps for its repair. It was found that not only could the work be carried out in Brazil itself, but in the naval arsenal of that country. It was therefore decided by the Ministry of Marine to proceed immediately with the re-casting of the damaged cylinders and liners, and great credit is due to the engineering officers of the Brazilian navy and to the personnel of the arsenal, not only for executing the work, but for the expedition with which it was carried out.

The photographs we reproduce are of the high-pressure cylinders of a quadruple set of engines, the respective diameters being 26 3-10 in., 38⅜ in., 56⅜ in., and 81½ in. by 54 in. stroke. The cylinders illustrated had been broken into hundreds of small pieces, and in order to make new cylinders to suit the set it was necessary to collect as many pieces as possible and to erect them as illustrated, so that the dimensions of the cylinders could be measured accurately. When erected, photographs were taken, and we are indebted to the Brazilian Minister in London for permission to reproduce these photographs. Portions of cylinders were also re-cast and welded in position in the engineering workshops in Brazil.

It is an interesting fact that most of the broken parts of the machinery were, in the case of the greater number of vessels, carefully stored between decks, evidently in order to be used as scrap metal in Germany in the event of the return of the ships to the "Fatherland."

## TRAINING ESSENTIAL TO FUEL CONSERVATION

Intelligent application of the principles of fuel conservation must be practised by every user of fuel throughout the coming twelve months to avoid a repetition of the past winter's plight. Wilful waste under existing conditions must not only be considered as a forerunner of woeful want but at the present time should be recognized almost as a criminal offence. "Keep the home fires burning," must not be taken too literally, but should apply rather to the fires of enthusiasm than to those of the hearth. The growing significance of this continental, if not world-wide, problem was forcibly presented at a recent meeting of the Canadian Railway Club, Montreal, when a paper on the subject of "The Fuel Situation in War Time" was ably presented by Mr. T. Britt, general fuel agent of the Canadian Pacific Railway; the substance of this paper appeared in the April issue of *Power House*. The largest gathering of the season was present, and the subsequent discussion indicated the extreme interest displayed in this momentous question.

Aside from the general adoption of methods and appliances to facilitate the saving of fuel the all-essential factor in the early or ultimate solution of this problem appears to be a better understanding of that ever-changing but equally unknown quantity—the human element. In suggesting that an educational campaign should be conducted among locomotive and stationary firemen, Mr. Britt pointed out the vital importance of personal instruction. He said:

"To my mind this should not be done by printed instructions but by actual illustration by competent firemen. While it is all very well to write a fireman and tell him what he should do,

it is far more educational for a competent instructor to show how it should and could be done."

Mechanical devices such as automatic stokers, the superheater, the brick arch, automatic fire door, feed water heater, together with the general design of engine mechanisms have all played an important part in the fuel saving movement, but the highest efficiency of any of these can only be attained when judiciously operated by the engineer or fireman responsible. Commenting on the poor quality of the fuel supplied during the past winter and the difficulties accruing therefrom, W. H. Sample, master mechanic of the G. T. R., said:

"So far as the conservation of fuel with us is concerned, I feel we do not do enough. We have undertaken to do some things but there are a great many more things that we intend to do. We have put on two additional travelling firemen with a view of instructing the firemen. That not only helps to save coal but it also assists in getting the trains over the road. We had to hire a great many new men, which is as great as factor in the fuel consumption as anything we have."

In agreeing that the question of fuel conservation was probably the biggest of present day problems, and pointing out the advantages that had resulted from the installation of mechanical devices for this purpose, W. H. Winterwood of the C. P. R. stated:

"A great deal of coal could be saved if measures were taken to prevent it falling from tenders along the right of way. In this connection I wish to say that Sir George Bury, vice-president of the Canadian Pacific Railway, has been vitally interested in the matter of fuel economy for years, and an order issued by him in the past was that locomotive tenders were not to be overloaded, and that the proper amount of fuel to be carried on the tenders be ascertained and that amount not exceeded. This has resulted in a great saving of fuel. He is also responsible for a modification and improvement in the design of our locomotive tenders. This change in design consists of a coal space with a very steep slope at the back which is brought much closer to the shovelling sheet than on any other tenders. The sides of the hopper are somewhat higher, but the coal in the hopper comes down by gravity to the shovelling sheet, eliminating the necessity of a mechanical coal passer and which insures all coal in the hopper being available. This has resulted in a great saving."

It was pointed out that it was not sufficient to equip an engine house or locomotive with fuel-saving devices, but in order to obtain the greatest efficiency from such installations it was imperative that the users should understand them thoroughly. In this connection, E. S. McMillan said:

"The Grand Trunk has spent a large amount of money on mechanical devices to save fuel and also to assist the firemen; as to teaching the firemen, we do this all we can, but it is very difficult on account of the large number of new men employed. I think the men co-operating with the engine crew in train handling should be properly trained in their work, for if not they can waste more fuel by unnecessary work than the engine crew can save. This condition will discourage the firemen very quickly."

In commenting on the vagaries of the human element and the direct bearing this often had on industrial problems, T. C. Hudson, master mechanic of the Canadian Northern, remarked:

"I feel that we should give more attention to young and inexperienced firemen, for that is where we meet most of our trouble to-day. Although we may have ideal conditions—such as locomotives equipped with superheaters, pneumatic firedoors, injectors proper size, tubes cleaned, and front end of locomotives properly adjusted, yet unless you have a fireman who can and will handle the scoop properly, coal will be wasted. It is true that we have a lot to contend with on the railroads in breaking in new men for road work owing to the fact that many skilled engineers have volunteered for overseas service. I am strongly in favor of travelling firemen who can accompany new and inexperienced men and demonstrate to them the proper method of firing a locomotive. You may equip a locomotive with all the fuel-saving devices possible (and the railways of this country have spent considerable on fuel-saving devices) but in the end we must come back to the human element if we are to get the best results. Printed instructions on fuel economy are beneficial from which an energetic fireman may learn much which will help him in his work, but these should be emphasized, and this can only be done thoroughly by demonstrating with the scoop on the footplate of the engine. We must admit that some of the coal supplied this year is of an inferior quality. However it is all we can get to handle the tonnage, therefore the fireman becomes a large single factor in any campaign to secure immediate results. Owing to the shortage of supply it will be found cheaper to educate the fireman than pay for the coal."

The better training of locomotive firemen was dealt with at some length by E. W. Sawyer of the I. C. school, and the thoroughness of this company's methods of education was demonstrated in his statement; he said in part:

"We have had an expert riding engines on one of the larger roads in and out of Montreal for some time in an effort to work out a system which would better results from the coal now being used on the locomotives on the road referred to, and it seems that it is not so much a matter of economy at this time as it is to evolve a system of handling this fuel and to keep the engines hot, especially when the fires get dirty and the grates clog with ash and other debris which so frequently occurs where coal is furnished high in non-combustible material."

Departing from the general groove of the discussion, A. M. Barry, of the St. Lawrence Welding ompany, brought up the subject of the firing and operation of marine boilers and their relation to the general problem of fuel preservation. To quote Mr. Barry in this connection:

"We have heard from the railways on the responsibilities of this fuel question and we have also heard from the power house man. What about the steamboat man? The steamboat man brings us back to the question of the human element. The steamboat man generally is a "wop" and is the cheapest kind of man that can be got. He knows nothing about fuel economy. His type is strong in the arm and thick in the head; his business is to shovel coal. You can see these marine boilers all over the country, in dredges, boats and elsewhere, with leaky and dirty tubes, tubes blocked and boilers dirty—two or three injectors on some to keep the water in them. The railroad man here to-night is being blamed for this fuel shortage but it seems to me that the steamboat man is equally responsible. When the fireman gets to the end of a trip he goes on a drunk, and if he does not turn up again it does not matter as they can get along without him. I do not mean the deep sea men, but the men on the inland waters—lake boats, dredges, and so forth. The railroad companies and those owning power plants may have reason to use greater economy in fuel but it seems to me they are not as great transgressors as the steamboat men. Why not get after them as well with education?"

From the above it would appear that the experience of the past winter will act as a stimulant to the adoption of every mechanical means available for the future saving of coal, especially in those districts where long haulage from the source is necessary. In addition to this increased attention will be given to the education of those men that are directly responsible for the actual burning of the fuel, so that the same may be accomplished in the most efficient and economic manner.

## AMERICAN NAVAL PROGRESS

ACCORDING to the 1917 annual report of the American Navy Department, there are upwards of 800 vessels being built for the navy, ranging from battleships to small petrol craft. It is also stated that a considerable number of 3-in. anti-aircraft mountings have been completed and supplied to ships in commission. Gratifying progress generally is recorded. The rate of production of armour-piercing projectiles has greatly increased and the quality of the projectiles now being delivered is better than it has been in the past. The almost unlimited capacity of the country for projectile making was indicated when sixty-none firms bid on one proposal and at prices lower than any previous tenders.

Methods, Machining Devices, Systems and Suggestions From Shop And Drafting Room

## BABBITTING AND SCRAPING HINTS FOR THE POWER HOUSE ENGINEER

By M. H. P.

TO make a bearing ready for pouring, secure the mandrel in position and make tight around the ends of the journal, either with putty or with moistened clay. When putty cannot be obtained, clay worked between the hands until free from lumps and plastic makes a very good substitute. In making tight around the end of the box, particularly where there is considerable space between the casting and the mandrel, take care not to press the putty or clay into the lining space. Should there be ¼ inch or more space some wooden heads should be cut out to fit the mandrel and clamped against the box casting. If it is a repair job and there is neither time or opportunity to fit heads, then rub some putty into a small cord and wind around the mandrel close against the end of the box. The cord will serve as heads, and some more putty daubed on the coils will make everything tight.

### Covering Mandrels With Paper

Bearings may be cast direct upon the shaft which is to run in them, but it is better to have a mandrel for that purpose. If the journal must be used, place a sheet of strong, smooth paper around the journal so that the babbitt does not come in direct contact with the metal. This is also excellent practice in all cases where mandrels are used for babbitting single boxes. Where many are poured in succession the mandrel becomes heated and does not chill the hot babbitt, hence the paper becomes unnecessary.

When poured directly upon the journal, babbitt pinches the shaft along the line of division between box and cap, and scraping is necessary to make the journal fit the box after the lining has been poured. The thickness of paper around the journal, combined with the shrink of the soft metal, relieves the journal so that on rough work little or no scraping will be found necessary, the arrangement of the liners giving all the adjustment necessary. On fine work, however, scraping will be necessary. In fact, all fast running and close fitting bearings should be scraped to fit the journal which is to run in it.

Sometimes the soft lining is peened to make it tight in the casting. When babbitt or other lining metal is poured into a cold casting the lining becomes chilled before the iron casting becomes heated, therefore, when the soft lining finally cools it shrinks away from the casting and becomes a loose, rattling nuisance which must be peened to make it tight in the journal bearing casting. Heating the box before pouring in the soft metal lining is a cure for looseness, as the iron casting then shrinks with the soft metal lining on cooling and holds fast when cold.

There is another way of fastening a lining tightly into a cold casting, and that is by using one of the antimony alloys as a lining. Antimony, when alloyed with lead and with some other soft metals, loses the power of shrinking during the freezing process, and like water expands and fills the casting so tightly that there is no rattle or looseness. Therefore, when forced to line a cold bearing, use an antimony alloy. It is for this purpose that the antimony alloy is used for casting printing type. The expansion of the alloy during the instant of solidifying or freezing causes the metal to expand into every corner of the mold. The same is true with the antimony alloy in the journal bearing.

### Forming Oil Channels

Oil channels may be formed in the lining by winding small cord around the mandrel. The cord should be of the hard spun variety and preferably should be rubbed smooth with putty before being wound upon the mandrel. The cord

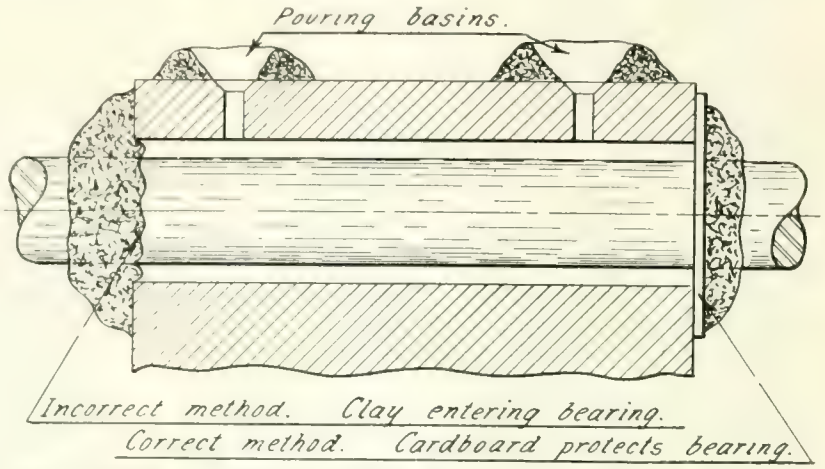

FIG. 1. RIGHT AND WRONG METHODS OF STOPPING OFF ENDS OF BEARING.

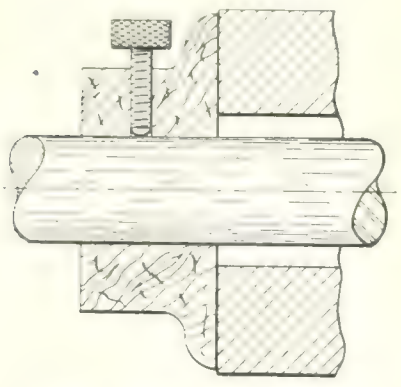

FIG. 2. THE USE OF WOODEN HEADS.

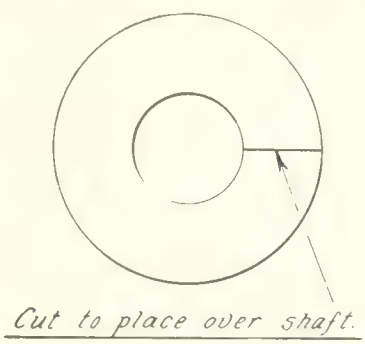

FIG. 3

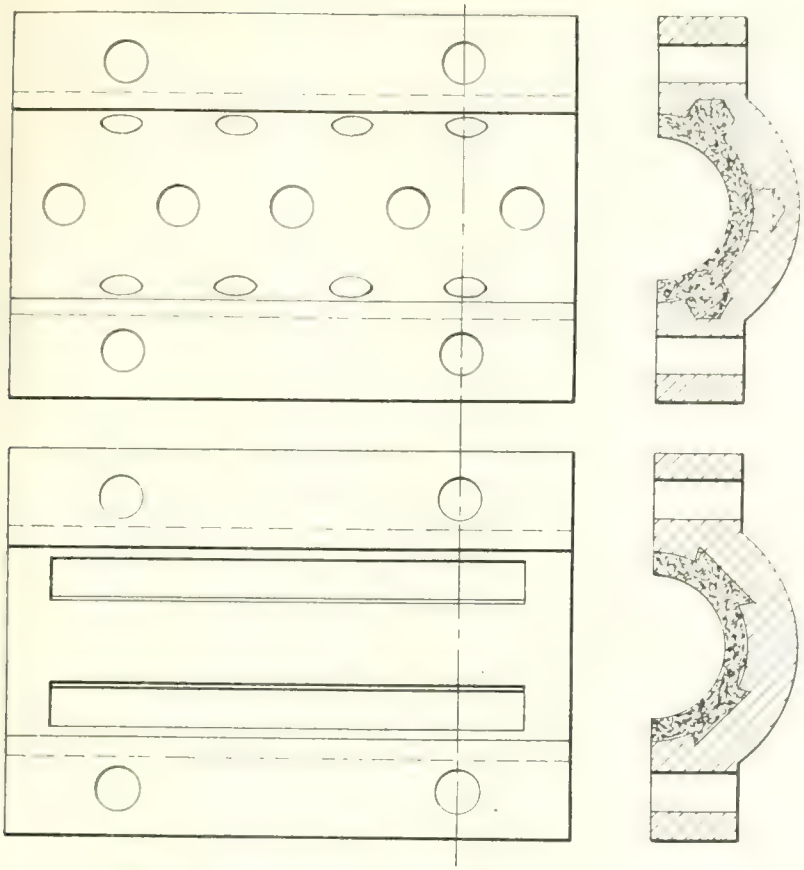

FIG. 1 METHODS OF KEYING BABBITT IN BEARINGS

must be wound in the direction that the shaft is to run. It does not work well when a passage must carry oil against the rotation of a shaft. When cap and box are to be poured together, cut two notches in each liner, one notch at one end, then clamp the cap in place, taking care that the liners are against the shaft before tightening down the cap bolts.

Bore one holes in the cap for pouring in the lining, besides the oil holes, then proceed to fit a white pine plug in the latter hole, fitting the plug tightly against the mandrel and let it project through the hole in the cap. After pouring, the cap may be easily removed by driving a cold chisel between cap and box, breaking off the metal which connects the cap and box linings through the four notches mentioned. These notches should not be more than ¼ inch on a side, and the section of soft metal lining being small is easily broken by driving in the cold-chisel. The four bits of ruptured metal should be carefully chipped or filed off smooth with the surfaces from which they project. Then drive out the plug in the oil hole and the cap is ready for scraping to fit the shaft.

### Heating Babbitt Metal

Before pouring a bearing, it is very important that the babbitt metal be heated to the proper temperature. This may be roughly determined by inserting a piece of wood—white pine or similar soft wood—into the hot babbitt and noting the effect upon the wood. It is best to whittle the stick to a smooth, flat surface, similar to the paddle used for stirring paint. The surface of the molten metal should be kept covered with a layer of charcoal to prevent oxidization of the alloy. Thrust the whittled stick through the layer of dust on top of the hot metal and note results to the stick. If the metal is too hot it can be felt to be boiling around the stick, which will be charred more or less, or not affected at all, according to the temperature of the molten metal.

It is certain that the metal is too hot when the stick trembles in the hand and smoke rises from the submerged end of the stick. When there is scarcely any trembling to be felt in the stick while it is immersed in the hot babbitt, then the alloy is ready to pour. If the stick is not colored at all and metal almost adheres to the stick, then the metal is not hot enough and it will not flow properly if poured at that temperature.

When babbitt metal is at the right temperature the stick will be faintly charred after being immersed three or four seconds in the molten metal. Two or three tests will blacken the stick even when the metal is not quite hot enough to pour, therefore it is best to whittle a new surface on the test-stick after each immersion.

### Pouring Soft Metal Bearings

Do not heat soft metal too hot, zinc is easily driven out of an alloy by too high temperature when melting, lead soon turns into dross upon exposure to the oxygen of the air when melted, and the higher the temperature of the melted metal the faster it will be rusted out by exposure to the air. It is for the purpose of preventing this loss of some of the metals that the surface of the molten alloy is kept covered with charcoal. But when the alloy is overheated, then oxidization proceeds much more rapidly and much metal is lost.

Do not skim the surface of the metal until it is clean of all dirt. When the ladle is tipped up, the bit of iron forms a floating dam which effectually prevents the covering of dirt from flowing out of the ladle, while the molten metal has free passage under.

When babbitt metal is melted in a pot, the alloy may be dipped out with ladles as required for pouring, and before dipping the ladle into the pot, push the covering to one side with the ladle, then pass the ladle below the surface of the alloy, taking care that the ladle is entirely submerged. Then lift the ladle out quickly and an excess of metal will be forced up by and above the ladle. As this excess of metal flows away, it forces back the charcoal covering on top of the alloy, and the ladleful of metal comes out of the pot clean, with no signs of dirt.

The metal must be poured very quickly when thus dipped up clean, for the reason that oxidization is going on all the time. Hasten the pouring operation once the

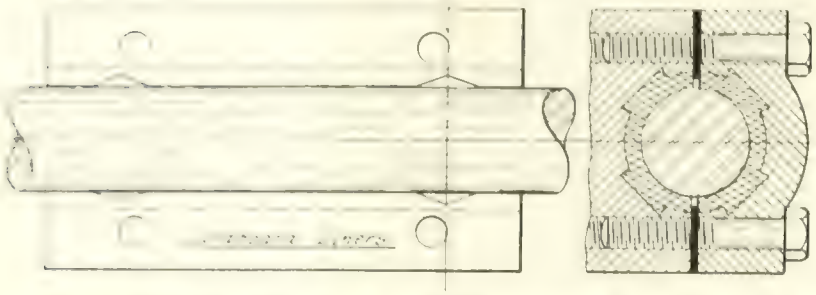
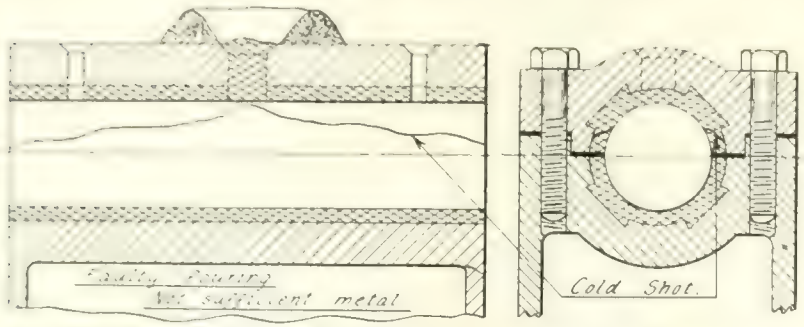
### Pouring Thin Solid Boxes

[illegible] must

spots. The remedy is to remove the metal at those points until the shaft touches at four or five places instead of at two or three. Then remove the four or five and secure a bearing at eight or ten. Continue this work until the shaft has a bearing in many spots. In this



[illegible] THE USE OF CARDBOARD LINERS IN POURING A SPLIT BEARING.



[illegible] THE RESULT OF FAULTY POURING. NOT SUFFICIENT METAL IN LADLE TO COMPLETE THE BEARING AT ONE POUR.

should be just high enough to slightly char a soft wood stick. But when thin solid boxes must be poured, and there is a long narrow or thin space to be filled with soft metal, then it is sometimes necessary to pour the metal hotter than described. In such cases the metals to come in contact with the soft metal should always be heated as much as possible before pouring in the lining. When a ladleful of metal fails to fill a box, do not try to fill the box by pouring hot metal on top of the cold. Take down and chip out the partially filled bearing, set it up again, and pour from a supply sufficient to fill the bearing.

### Scraping Bearings

In order to make a first class babbitting job the scraping operation is necessary. Even for rough work, should it be possible to make a good bearing without scraping, a better one can be made if the operation of fitting the bearing to the journal be carefully followed out. unless the journals are properly fitted to their bearings it requires a great deal of preliminary running so that the bearing will not heat. When a shaft hits a bearing only in two spots, at opposite sides and ends of a bearing, it cannot be expected that the shaft will run cool and steady in that bearing.

[illegible] a bearing and given a turn or two, and black spots appear in two or three parts of the babbitt with no marking elsewhere, then it is sure evidence that the shaft touches the bearing only at those two or three way innumerable points of bearings could be obtained between the shaft and the babbitt, and it could be assumed that they touched each other at all points and that the contact between them was practically perfect.

When fitting a bearing to a shaft as above, the blackened spots are removed by scraping, hence the name of the operation becomes that of scraping a bearing. A good job of fitting as above described may be done by the use of a common carpenter's chisel. By the use of this tool the blackened spots may be removed. A little plumbago or red lead mixed with oil and rubbed on the shaft each time will leave new spots to scrape off and the operation may be continued indefinitely.

## PACKING CASE ECONOMIES

By M. L.

A French inventor having remarked the damage that packing cases frequently suffer on opening, even when the well-known nail-puller is used, has devised a method by which the drawing of nails is greatly facilitated. He provides a washer of soft materials—such as scrap leather, hard paper or fibre—which is put on the nail before driving and which prevents the head from sinking to the level of the surface of the board. When the box has to be opened it is easy, with a pair of pincers or the usual opener, to grasp the head securely and draw the nail promptly without splitting the board.

There are various ways of opening a case. One way is to drive a wedge under the board to raise it, but this method is liable to split the wood. A better way is to hold a piece of 1 inch by ¼ inch bar iron against the lower edge of the board and strike upwards with a hammer so that the edge of the iron meets the edge of the board along its whole width; the blow is thus distributed and the board is not split. To dismount a box entirely, if big enough, a bit of one-inch board may be laid close up to a corner and struck smartly with a hammer to loosen and to draw the nails. To detach the bottom, a piece of the cover may be applied endways with a mallet to loosen the boards. A little judicious thought may save much waste in the opening and altering of packing cases.

## REMOVING PAINT

One of two methods of removing paint is usually adopted, either "burning off" with a blow lamp, by the flame of which the paint is softened in front of the tool which scrapes it off, or "pickling," by which the oils are destroyed and the pigment left ready for removal, and in which some strong caustic alkali is used, being adopted. Usually on metal the paint is best removed by pickling and scouring, but in every case the most suitable process should be used, a large amount of judgment being usually required in deciding which is best.—M.M.

# Underlying Principles of Forging Machine Die Design *

By E. R. Frost **

*Much information has been gained through experience by those who are familiar with forging machine die design but little of it has been made available or classified. Failures are usually found to be the result of neglect of certain of laws governing successful practice.*

IN preparing a paper on rules or methods for designing forging machine dies, the writer was confronted with the difficulty that but little information contained in such a paper would be new to your members, as experience has taught you most of the pitfalls in forging machine die design.

It is possible, however, that some of you may not have so classified the information gained that it could be clearly expressed in rules, and, as such, passed to your assistants. It is our experience that at least seventy-five per cent. of the failures in forging machine die design can be attributed to the disregard of one or more of the fundamental laws pertaining. The desirability of having this information expressed in the form of laws makes the excuse for this paper.

The only apparent way to make a paper on such a subject clear is by illustration, hence this information is presented in graphic form, with the hope that it will be of value to your men in the shop, and will serve to reduce the expense for dies, the failure of which might be anticipated.

Throughout these remarks the policy is followed of not taking into consideration unusual methods; trick heats; welding operations; or, in fact, any laboratory methods which, while possible under certain conditions, are unpractical in average shop practice. Consequently, while certain statements may appear to be too limited, they will, in the main, be found as applying to average conditions.

It is possible to classify the majority of forging machine die problems under three rules or headings, which are as follows:

**Maximum Unsupported Length of Stock**

RULE No. 1. The limit of length of unsupported stock that can be gathered or upset in one blow without injurious buckling is not more than three times the diameter of the bar.

As an example, by reference to Fig. 1, if the diameter of the bar "A" to be upset is 1 inch, then the length of unsupported stock "B" which may be successfully gathered cannot be more than 3 inches. This rule applies on all diameters of stock. As three diameters, however, is practically the limit, it is best to keep the actual working limit within two and one-half diameters; and where it can be done, even a limit of two diameters is better, as then less attention need be paid to the squareness of the end of the bar. On such upsets, as the heading tool advances, as indicated in Fig. 2, the stock will swell uniformly in all directions from the axis of the blank, and it can be carried to practically any thickness, such as shown in Fig. 3, without any serious tendency to upset unevenly. It is immaterial whether the stock overhangs the face of the gripping dies, as in Fig. 1, or whether part of the stock is gathered in the gripping dies and part in the heading tool, as in Fig. 4; whether it is all upset in the gripping dies, as in Fig. 5, or all in the heading tool, as in Fig. 6—the fact must be kept in mind that such conditions represent cases where the stock is unsupported, and hence Rule No. 1 applying to three diameters or less of unsupported stock will apply.

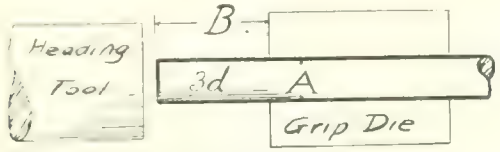

FIGURE 1.

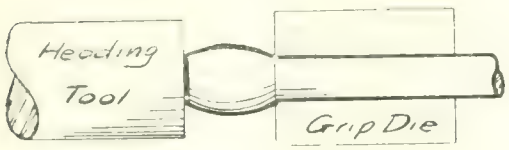

FIGURE 2.

FIGURE 3.

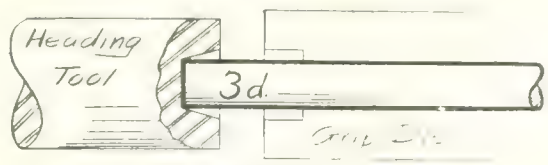

FIGURE 4.

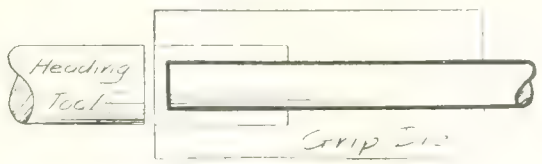

FIGURE 5.

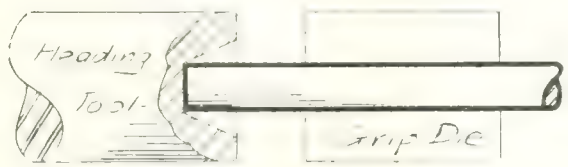

FIGURE 6.

Many simple forgings come under this ruling, such as the level pinion forging shown in Fig. 7; the grease cup spring shackle bolt, Fig. 8, or the ring forging Fig. 9. In each case, the distance from the heated stock to the inner surfaces of the gripping die impression or the heading tool, is such that the stock is in reality unsupported.

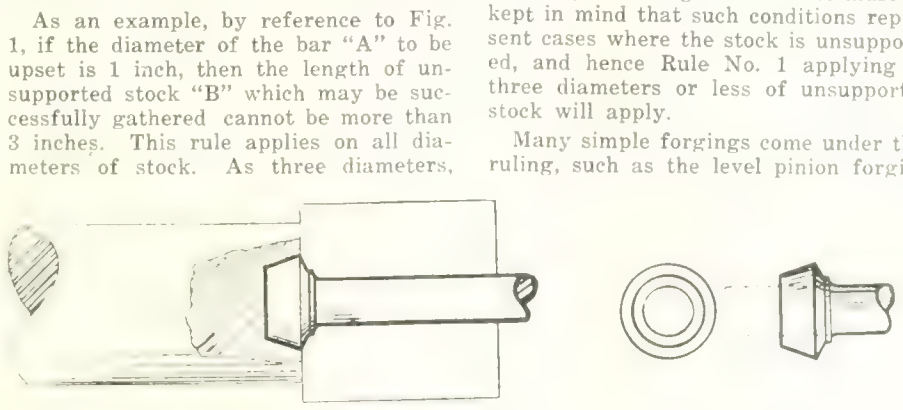

FIGURE 7.

* Read before the Fourth Annual Convention of the American Drop Forge Association at Cleveland, Ohio.

** General Manager National Machinery Company.

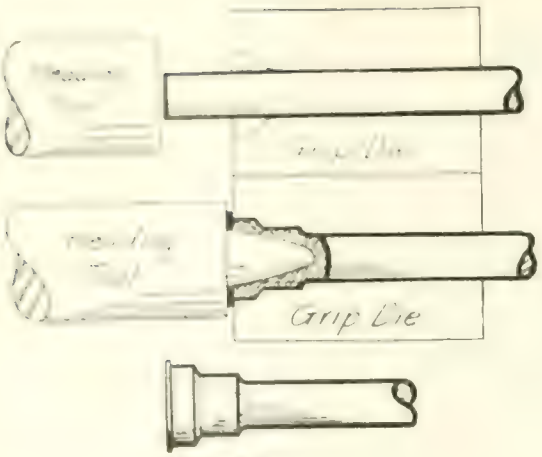

FIGURE 8.

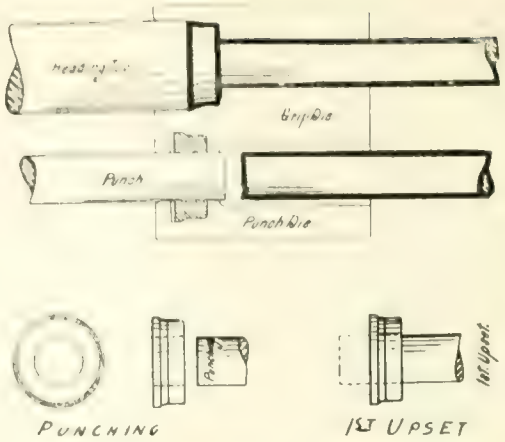

FIGURE 9.

In order to insure the dependability of Rule No. 1 no effort is made to upset a length of stock longer than three diameters, in place of upsetting uniformly, as shown in Figs. 2 and 3, the stock will buckle at a point near the middle, and result in more of the upset forming on one side of the centre of the bar than on the other. As an example, in Fig. 10, assuming that the diameter of the bar "C" is 1 inch, and the length of unsupported stock "D" is 4 inches, then when the heading tool advances, the stock will start to buckle, as shown in Fig. 11, and after it has once started, will, of course, continue, as illustrated in Fig. 12. It is merely an application of the general principle that under pressure given lengths of any material will either crush or bend.

It is impossible to correct this condition by varying the point in the die where the upsetting takes place, as it will be readily seen from sketches 13, 14 or 15 that the stock will buckle, regardless of whether it is upset in the gripping dies, in the heading tool, or part in the gripping dies and part in the heading tool.

**Effect of Upset Diameter on Upsetting**

RULE No. 2. Lengths of stock more than three times the diameter of the bar can be successfully upset in one blow, provided the diameter of the upset made is not more than one and one-half times the diameter of the bar.

This rule, while fairly well recognized, requires a clear understanding in order to develop its practical possibilities.

By reference to Fig. 16, assuming that the diameter of the bar "E" is 1 inch, and the length of stock "F" to be upset is 6 inches, and that the diameter of the hole "G" in the die is not more than 1½ inch, then when the upsetting begins, as in Fig. 17, the stock will at once buckle, but on account of the limited diameter of the hole "G" the stock soon comes in contact with the sides of the die. This prevents further buckling in this direction, hence any additional upsetting must take place at some other point. The stock will frequently be found to buckle at several points, as in Fig. 17; but as the heading tool advances, the stock will gradually fill the impression in the die, as shown in Figs. 18 and 19, resulting in an upset as in Fig. 20—the only objection being a fin around the end of the upset.

If an attempt is made to produce a forging in a die in which the diameter of the hole in the die, as at "H" in Fig. 21, is greater than one and one-half times the diameter of the bar, then when the upsetting begins the buckling effect at some point—and generally near the middle of the unsupported stock, such as at "I" in Fig. 22—is sufficient so that when the heading tool continues its advance, the stock on the opposite side from the buckled portion, such as at "J." Fig. 23, will fold "in," and, of course, leave a defect in the upset.

As in the case of Rule No. 1, while it is possible to make forgings in which the diameter of the opening in the die is as much as one and one-half times the diameter of the bar, nevertheless, this is very close to the limit, and in practice it is much better to keep the diameter of the upset not more than 1.3 times the diameter of the bar.

The practical application of this law is in the ability to gather large amounts of stock by repeating the principle, as indicated in Fig. 24. In the first, or top impression, the diameter "K" of the recess in the die is not more than one and one-half times the diameter of the bar "L." In the second impression the diameter of the recess "M" is not more than one and one-half times the diameter of the previous upset "N." In the last impression, the length of the upset "O" is well

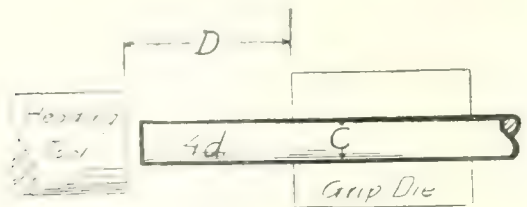

FIGURE 10.

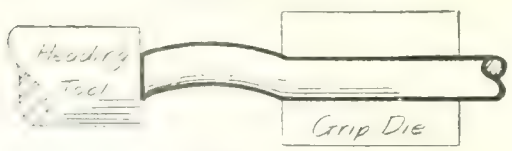

FIGURE 11.

FIGURE 12.

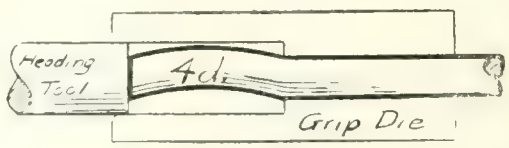

FIGURE 13.

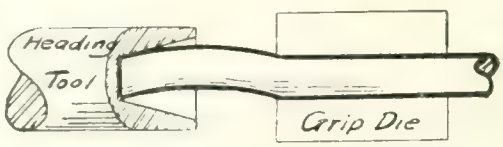

FIGURE 14.

FIGURE 15.

within the limit of Rule No. 1 regarding unsupported stock, so that no limit need be put on the diameter "P" of the last die impression.

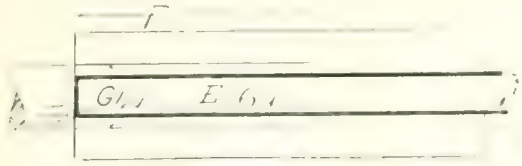

FIGURE 16.

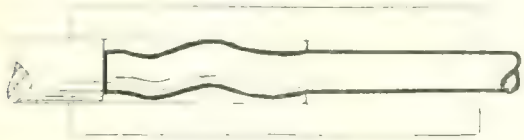

FIGURE 17

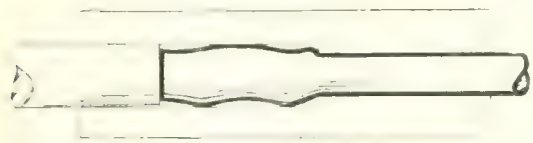

FIGURE 18

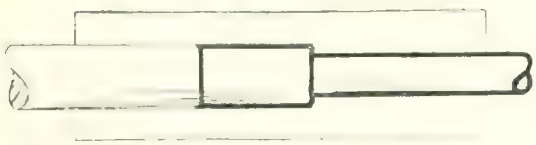

FIGURE 19.

the impression in the die is made not more than 1.3 times the diameter of the bar, as in Fig. 27, then the upset formed will be free from fins on the end of

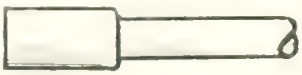

FIGURE 20.

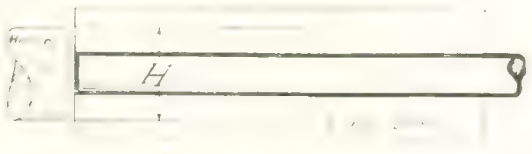

FIGURE 21.

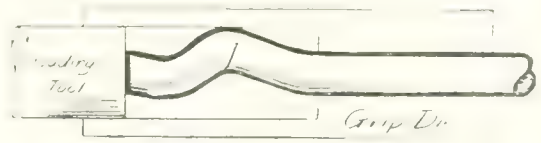

FIGURE 22.

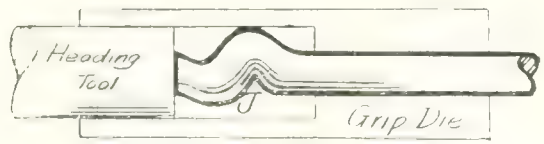

FIGURE 23.

dle of the unsupported portion, and as a result, somewhat more than one-half the stock to be upset, as at "Q," Fig. 31, must be inside of the impression in the die. It can equally well be in a taper or straight hole in the heading ram, as in Figs. 32 and 33; but it is useless to attempt to make part of the impression in the gripping die, and part in the heading tool, as in Fig. 34, because when the upsetting begins, as in Fig. 35, the stock will buckle, leaving a defective forging as shown in Fig. 36. To attempt to sup-

This principle is clearly shown in Fig. 25, in which, in both the first and second operations, the diameters of the impressions have been kept within this limt.

The same principle applies to the first two operations in the upsets shown in Fig. 26. In such upsets, where the length of stock in the first operation is excessive, it is generally necessary to the upset, even if no special care is taken in heating. This is on account of the fact that where the length of the stock is not more than three diameters, the upsetting takes place quite uniformly throughout its length, and any buckling being limited, the friction of the stock along the side of the die does not become a factor.

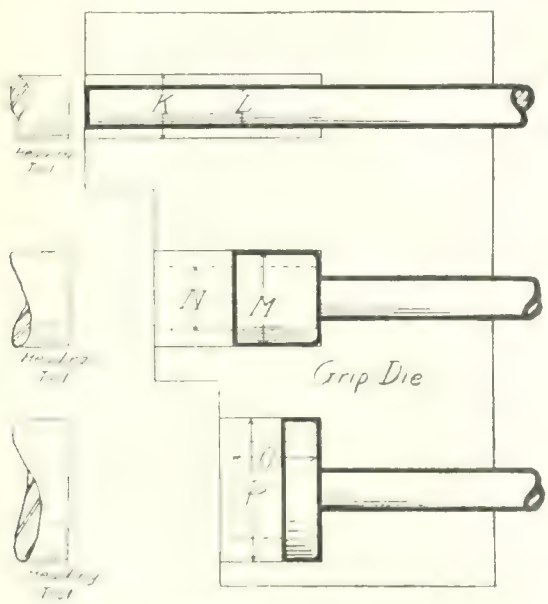

FIGURE 24

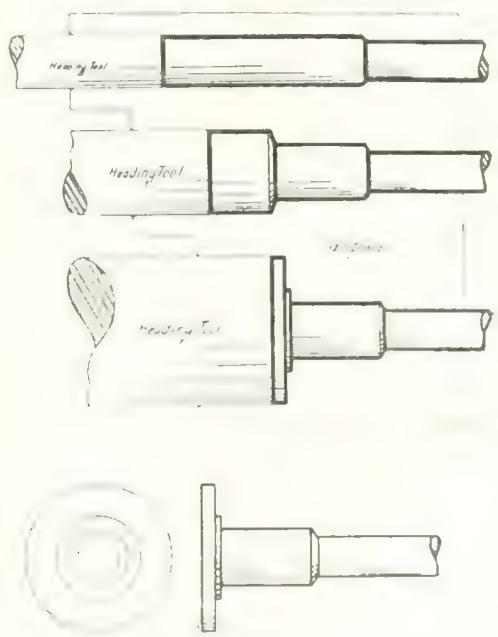

FIGURE 25.

keep the end of the bar at a lower temperature.

Where it is desirable to carefully hold the size of some upset in which the stock requirement is not materially over three diameters in length, if the diameter of

Forgings shown in Figs. 28, 29 and 30 come in this class.

In handling all upsets requiring more than three diameters of stock, the fact must always be kept in mind that the stock will first start to buckle at the mid-

port the end of the bar in the heading tool, as in Fig. 34, does, of course, help, but the final result will be a defective forging as indicated in Fig. 38, on account of the lack of support near the middle of the upset, as suggested in Fig.

sion in the die support the bar, and keep it from buckling; but the greater area of the square hole enables a larger amount of stock to be gathered than would be possible were the hole round.

the die impression, also prevent the bar from buckling and allow a large amount of stock to be gathered. If the length of the stock as it leaves the second operation has been shortened sufficiently to

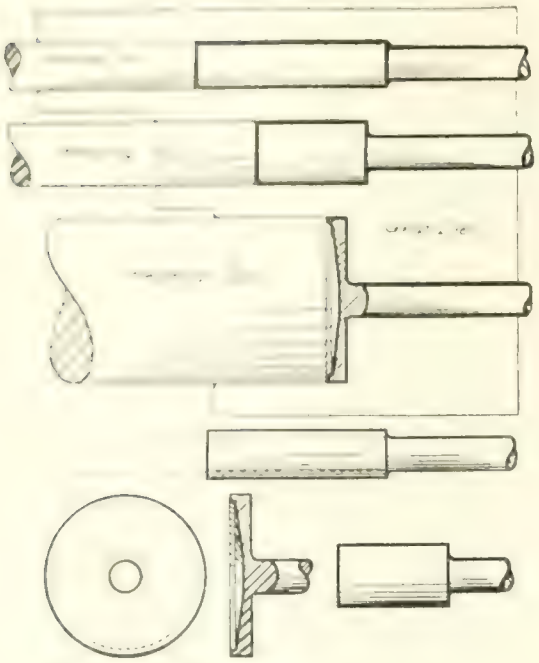

FIGURE 26.

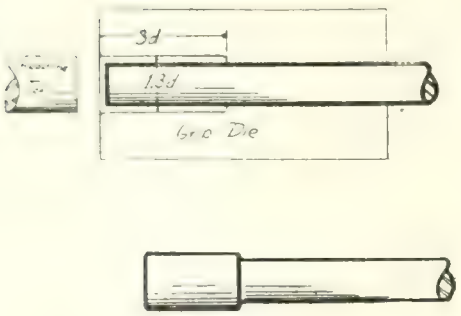

FIGURE 27.

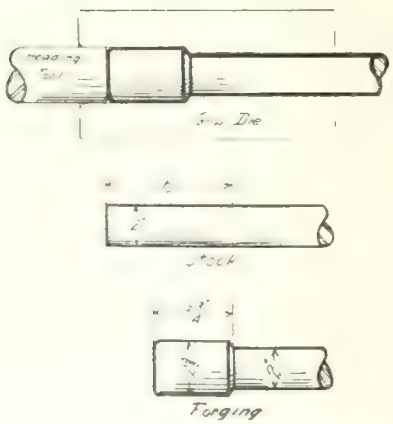

FIGURE 28.

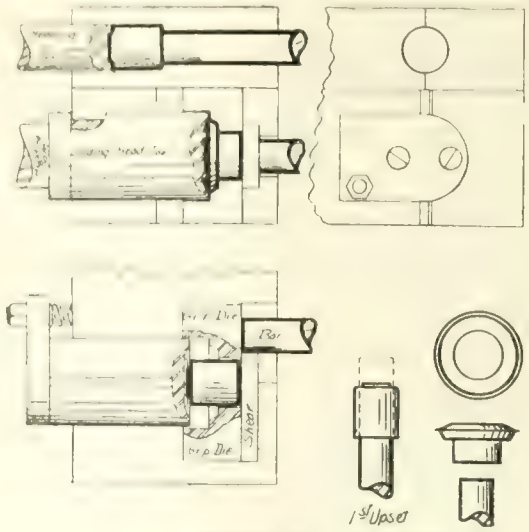

FIGURE 29.

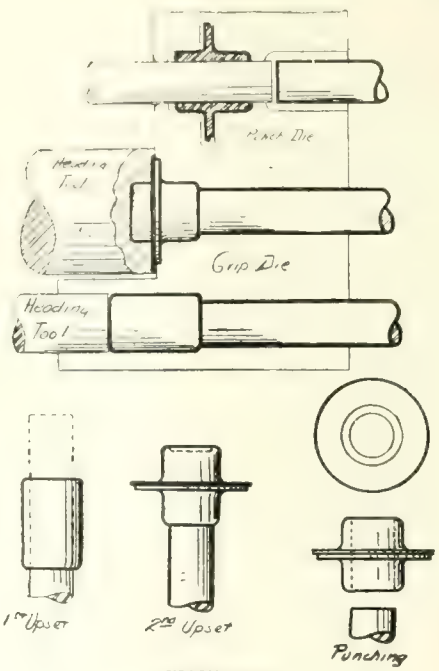

FIGURE 30.

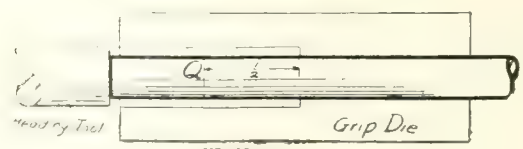

FIGURE 31.

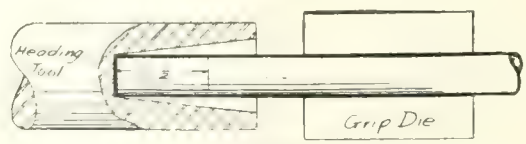

FIGURE 32.

an extra amount of stock is obtained in the first upset by making the first impression square, in place of round. The short diameter of the square hole, as at "R," is made within one and one-half times the diameter of the bar. Consequently, the corners of the square impression will be filled in the first upset. The next impression is made round, and the diameter of this impression, as at "S" can be one and one-half times the long diameter, or in other words, the diameter across the corners of the previous square upset. The square corners, by coming in contact first with the sides of

come within the requirements of rule No. 1, then it can be formed in the last operation into any desired shape without regard to the diameter of the die impression. The practical application of such a method is shown in Figs. 40 and 41.

## IMPROVED DRAWING-BOARD COVER

By M. M.

In a great majority of drafting rooms the ordinary buff drawing paper is used to cover drawing boards. It is not long before the paper is soiled and marked up with pencil marks and ink-spots. There is also another disadvantage—in damp weather the paper becomes loose on the board, making it disagreeable to work on.

A drawing-board cover treated in this way will never loosen up in damp weather, and it is hard to write on, therefore the cover will always look tidy and clean. In case some ink spots or other stains get on it, they can be washed off without any trouble.

FIGURE 33.

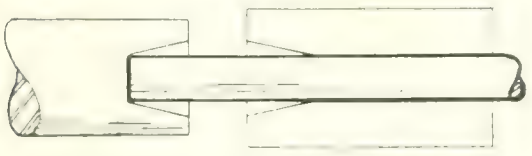

FIGURE 34.

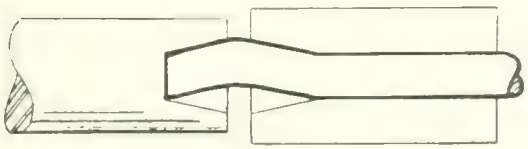

FIGURE 35.

FIGURE 36.

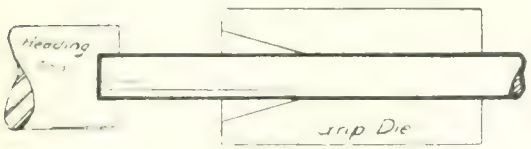

FIGURE 37.

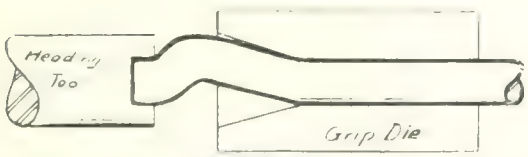

FIGURE 38.

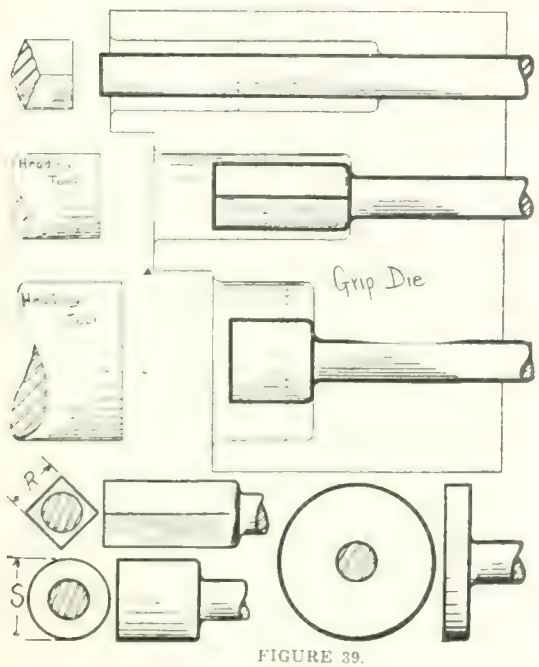

FIGURE 39.

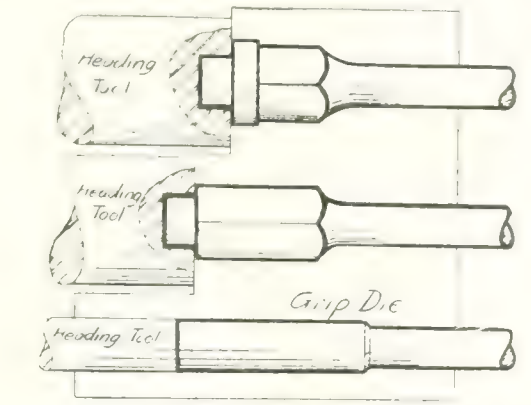

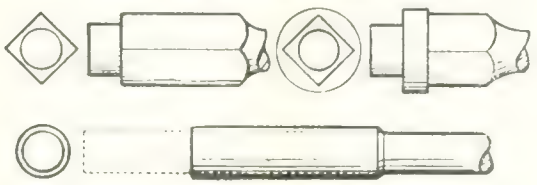

FIGURE 40.

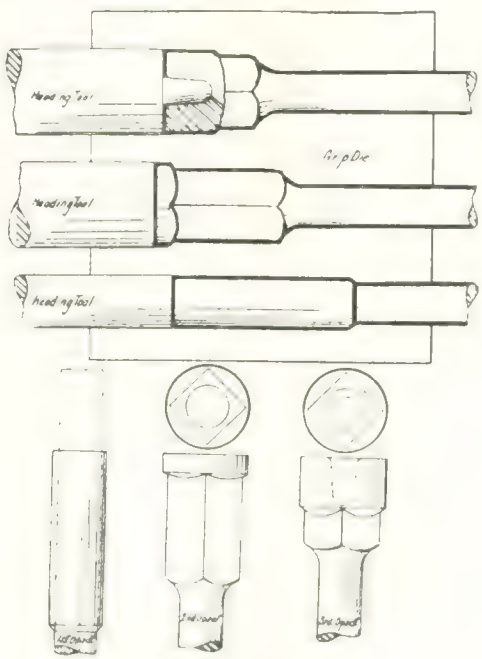

FIGURE 41.

A good way to do away with all this is as follows: Cut the paper the required size and rub over it with a damp cloth. The water on the paper will make it expand; then tack the paper to the board; the tacks should be about 2 inches apart. In a little while the paper will tighten up and dry, when a coat of shellac should be spread over it.

It takes a little longer to put on a cover like this, but it is worth while, considering how much longer it lasts than the other kind. The only reason for ever taking the cover off is on account of so many tack holes, but for these it would last indefinitely.

**Toronto, Ont.**—Among the appropriations tabled in the Legislature recently was $686,000 for the T. & N. O. Railway.

## THE MUNITIONS "PROFITEERS"

LARGELY as the result of the efforts of the members of the tin-pan section of the public press the people have been given the impression that all shell makers are "profiteers" and all who have to do with shell contracts are "grafters." Some recent incidents at Ottawa have done much to relieve this impression although there was not any great effort shown to give them that publicity required to remove public misapprehension. On the floor of the House of Commons Sir Sam Hughes, referring to the "profiteering" in munitions manufacture, said:

record is as follows: Twenty-five per cent. of those who entered into the manufacture of munitions completely failed and lost their money, and I have yet to find any person express the slightest bit of sympathy for any of these poor beggars who put up their own money—not the Government's money as was done in Great Britain and the United States, but their own money—and then failed in the manufacture of munitions. Fifty per cent. came out a little more than even, and about twenty-five per cent., owing in some instances to good work and in others to slight encouragement from the Munitions Board and elsewhere, succeeeded in making money.

Twenty-five per cent. of the munitions contractors lost money; fifty per cent. came out even and twenty-five per cent. made money. How little has the public understood of this. The cases of some few concerns which by their exceptional positions made big profits—much of which went back to the Government in taxes—have been held up to represent a general condition, and those patriotic men and companies, after putting up their capital and experience for the national good have received no thanks, but, on the other hand, have been made the targets for those who revel in the cheap political effect of the plaudits of a misunderstanding public.

The zest with which recent references to percentage arrangements by the Imperial Munitions Board have been developed into charges—by innuendo—against Sir Joseph Flavelle and the seeming reluctance with which explanations in refutation have been made is only another indication of the Bolsheviki tendencies which are being fostered and which seriously menace that all-important but little understood national institution known as business.

## CANADIAN MACHINERY PROSPECTS

LATE advices from machinery sources in the United States indicate the probability of capacity being taxed to the utmost well into 1920. The continued needs of the nation for war purposes are compelling builders of large tools to undertake extensions in preparation for increase in business.

In view of the labor and output situation, the call for over eighty millions of 75 and 155 mm. shells during 1919 would indicate the necessity for Canadian machine tool builders being prepared to maintain the engineering industry at full efficiency with their own resources.

Much of this shell work will doubtless come to Canadian shops, and with tool-building loaded up in the States, our own builders should find increased opportunity.

## SHIPPING NEEDS OF THE FUTURE

CANADIAN exports to the amount of many thousands of tons are, according to Commissioner Ross of the Trade and Commerce Department at Melbourne, held up in this country owing to lack of shipping facilities to Australia. Ships are required elsewhere owing to the exigencies of war. For the present Canadian manufacturers must be prepared to face such conditions—the military campaign is the first consideration—but what of the future?

A nation which hopes to supply other nations with her products, particularly manufactured products, should be prepared to make delivery—and delivery means ships. Canada as an agricultural country may for the present, and in the future while there is an insistent demand for food stuffs, be in the position of being able to make buyer nations take delivery at the seaboard with their own ships. This will not be the case with manufactured goods, particularly as those nations which take our food exports will not only refuse to carry other products, but they will expect to bring manufactured products to us. This on the economic basis of settling for purchases and for the business reason that successful transportation demands cargo in both directions.

All indications are that if Canada wishes to play a part in the Pacific trade after the war, and to extensively export manufactured products, especially where there is national competition, she will require her own vessels to deliver the goods. This should be considered as a factor in relation to any shipbuilding program which on the face of it may not promise to be a financial success. It is under such circumstances that national industry looks to the Government for assistance.

## U.S. AUTHORITIES TO GATHER INFORMATION IN CANADA

CANADIAN factories will be visited in the near future by a sub-committee of the Senate Committee of Military Affairs from Washington as a result of the present state of the munitions industry in the United States.

Authoritative advices state that the present output of war munitions across the line is only 75 per cent. of what it should be. "This is due," says the United States Employment Service, "to the lack of mechanics and toolmakers."

The necessity for greater production is so urgent that this organization has made an appeal to all manufacturers of non-essentials to reduce their production so that the labor supply available for war uses may be increased. Reserve lists of workers in non-essential industries who are willing to take up war work will be utilized by the Employment Service in its effort to get help.

These facts lend weight to the belief that munitions orders for American account will continue steadily for some time. This is equally as gratifying as the statement in the opening paragraph. It appears that the sub-committee referred to was named as a result of the delay in supplying large guns for the American Expeditionary Force, and its present tour of steel plants and ordnance factories is expected to include representative Canadian factories so that a comparison of methods can be made.

The manner in which Canadian factories measured up to their demands before the war was a year old justifies confidence that the comparison will not be to our disadvantage.

# GOOD TRAINING AT START MEANS MUCH

**W. J. Rennie Says His Experience Under Careful Montreal Mechanics Has Meant Much To Him In His Mechanical Career**

"THE very best thing that can happen to a young mechanic is to learn his trade with a man who is the master of it." That's the conviction—not simply the opinion—of W. J. Rennie, superintendent of the Toronto Type Foundry on Coleman Ave., at eastern limits of Toronto. "As I look back over my life, I can thank such men as J. and R. C. Weir, of Montreal. It was in their marine shop that I went as a boy of 15 to learn the machinist's trade. Apprenticeship at that time lasted for six years, but when an apprentice finished his six years in the old Weir shop he was a mechanic — or it wasn't the fault of the firm."

W. J. RENNIE.

Mr. Rennie is particularly well known to the machinery trade in Montreal, from which place he came to Toronto when the Type Foundry went into the making of munitions about three years ago. He was with the Canadian Linotype Co., for many years as superintendent, for a period of some 19 years.

### A Friendly Feeling

"It's a good many years," stated Mr. Rennie, "since I first left Montreal, but there's one little incident that I never shall forget. It brought a lump in my throat at the time. The day I was leaving the Weir shop as a full fledged machinist, James Weir came outside the shop, and taking me by the hand, wished me success. Then he pointed to the sign on the shop that carried their name and said, 'As long as that's above the door there's always a job here for you.' I never went back to get that job, but just the same it was a great start for me to get on my first trip out."

### Not Much Equipment

"I remember well the first place in Bridgeport that I applied for work. We didn't carry such an outfit as many of the men do now. The first thing the superintendent asked me was where was my outfit. That was in 1890. I told him I had it with me. So I did, my overalls, hammer, calipers and a two-foot rule. The job he set me at was cutting a key way in a very large wheel. I finished it in short time because I knew exactly how to do it. The superintendent came over and looked the job over, put the rule on it and nodded. I remember quite well he turned and said, 'Say, where did you learn your trade?' I told him, and believe me I was thankful right there and then for the training I had received at the old Weir shop. The superintendent was mightily pleased with that first job."

### Went Into Special Work

Shortly after this, Mr. Rennie went into more special works, entering the plant of the Armstrong Die Works, also working in New York and Springfield. "That was one time in my life when I used to have lots of money," laughed Mr. Rennie. Firms were paying well then for special tool work, and a friend of mine worked with me—things were good then. Four years after I returned to Montreal and after being in the Linotype factory for six months I was made foreman, staying there for ten years, after which I became superintendent. I was there for 19 years altogether." About that time the Canadian-American Linotype sold to the Mergenthaler Co., Mr. Rennie then going as superintendent with the Robert Mitchell Brass Works. He afterwards became a partner in the firm of Decatur, Bull & Co., makers of tools. A disastrous fire wiped them out, and Mr. Rennie came to Toronto to put in and operate the shell plant of the Toronto Type Foundry, where a large number of 4.5 orders were successfully machined.

### Developed New Ideas

While the work of turning out shells was going on, Mr. Rennie turned to the task of improving the methods adopted. His thread-cutting machine, knurling machine and nosing die were brought to completion in quick order. Moreover they were adopted in many of the other shell plants. Just recently Mr. Rennie has developed a grinder that will soon be put on the market. Technical men who have looked over it state it is a workable, simple machine, possessing many new points that will make for accuracy and greater production. "For almost 30 years I have known that grinders were wrong," stated Mr. Rennie, "and each new one that came out seemed to carry some of the old faults with it. In short they were too complicated and too hard for anyone but a skilled man to adjust. I will be ready to tell you more about the grinder later on."

### Regarding the Apprentices

In answer to a question regarding apprentices, Mr. Rennie replied that he liked to secure them about 16 years

# THEY SENT FOR SCHWAB

SOME men go a-tinkerin' on and get there fairly fat, and blunder till they get out straight about this thing and that, and in that way they seem to pass and get through with the crowd, 'cause no one ever calls their bluff, and calls it good and loud.

It beats the band how they get past and no one biffs their lids, you'd think it was a slide for them with grease upon the skids.

But these things change when things go wrong, when sand gets in the cogs, and when the road gets piled up deep with bricks and stumps and logs, and when the works turn up on edge and things get out of sorts, and when the engine fades and dies or wheezes bad and snorts.

Why just the other day a case came up in Yankee land, where folks had reckoned they was goin' right fit to beat the band.

When war got started over there they went in on a rush, with fifteen different kinds of steam and forty sorts of gush—the steam was blowin' from the valves, the stokers stripped by heck, until the hunks of dew and sweat was campin' on their neck.

Until one day they counted up and found with all their fuss, their whole caboose was turnin' out a funny lookin' muss.

'Twas then they found their middlin' men was fallin' down for fair, and they needed men whose heads was decked with somethin' more than hair. So then they looked around a spell and sputtered 'bout the job, until one jay piped up and said "let's send for Charlie Schwab."

It's just the same thing all the time no matter where you turn, from pickin' stones or heavin' coal or tinkerin' with a churn.

Things seem to run on fairly well when pressure's not too strong, or when the cash is plentiful and the purse is good and long, but when them things they cease to be, when wheels they cease to hum, and when the whole durn shootin' match seems goin' right on the bum, it's then they want a real live man to tackle that there job, so they do what Uncle Sam'l did when he called in Charlie Schwab.

# MARKET DEVELOPMENTS

## Will Canadian Steel Prices Be Fixed?

### Business Very Brisk, With War Work Having Preference Over All Else—Prices Very Firm With Few Changes in High-Speed Goods—Copper Prices Seem Likely to Remain at Present Levels After June 1

DEALERS in steel in Canada are looking for some form of price control, apparently anticipating action from Ottawa. As a general rule prices in Canada are well above the United States prices, in some cases working to the decided disadvantage of Canadian manufacturers.

The business of supplying plants on munitions orders with material does not show any sign of dropping off. The great quest at present is to secure machine shop capacity to turn out the special war purpose machinery that is being so insistently called for. New plants for war business are being put in at Montreal and Toronto, while others are tooling again to change from 6-inch to the 9.2 orders, these plants having previously been engaged on this class of work.

A satisfactory volume of business is coming to Canada from American sources, but the publicity which certain Canadian papers continue to give to this class of work makes it harder for the Canadian War Board at Washington to work to advantage.

Production is satisfactory at American mills and great success is attending the effort to catch up with war demands. The demand for scrap metal is insistent both in United States and Canada. As a general thing yards in this district are almost bare.

The drafting of men from the coal areas of Sydney is being watched with some interest. It is estimated that production there will fall at least 25,000 tons a month.

The trading in non-ferrous metals continues to be about the same, no new features appearing. Canadian dealers claim that on entering the United States fixed market they have to pay well over the fixed price in order to secure supplies. Small lots of Chinese tin come through at intervals, but it is very scarce, irregular and high in price.

Canadian dealers do not anticipate changed copper prices on June 1, when the present schedule expires. They point out that it is easy to secure supplies. The agitation for a higher price is being carried on by the mine group.

## AMERICAN REGULATIONS ARE REFLECTED IN MONTREAL NOW

Special to CANADIAN MACHINERY.

MONTREAL, Que., May 14.—The situation throughout the district has taken on a nervous tendency owing to the acute nature of the supply of steel and other materials. As Canada is dependent on the mills in the States for her requirements in this respect, the American conditions are more or less reflected in the market here. Owing to the announcement that practically 100 per cent. of the mill output in the States will be utilized for government purposes, the domestic needs of both countries will require to be curtailed to the very utmost. The increase in shell orders is the feature of the week. One Montreal plant that has formerly been making shell machinery is enlarging its place for the manufacture of a large naval shell. A branch of the metal industry that is apparently expanding is that of electric and oxy-acetylene welding, two local firms during the past week having more than doubled their previous capacity. Developments in marine activity are largely responsible for these extensions. The break in the Lachine lock has not been entirely repaired, but navigation was interfered with very little as they were able to move the larger vessels through as soon as one pair of gates was placed in position.

#### Pig Iron

The situation in pig iron is relatively a war market, as all available material is practically reverted to the manufacture of war essentials. Furnaces have been working to capacity, but have often been forced to curtail the output owing to the lack of obtaining a sufficient supply of coke and other raw materials. This has become less pronounced, due to the fact that delivery has been more regular during the recent weeks. Dealers here report that little or no iron is available for ordinary purposes. Quotations are withheld or are quoted as a nominal figure.

#### Steel

If it were possible to show additional tension throughout the steel industry, the same has recently been the case over the rumor that changes might be looked for in the price of certain commodities, and that in all probability these changes would be in an upward direction. The demand for steel is still heavy. Little improvement has been shown in the delivery of material, and every ton of steel used in the manufacturing field at the present time is virtually utilized for war purposes. Dealers here report great difficulty in obtaining shipments from points in the States, and intimate that this may become still further emphasized in the early future. The regulations regarding the disposal of material are becoming additionally strict, and specifications must accompany every order for steel. The great trouble appears to be the distinction that should be made as to just what constitutes essentials, as many activities apparently engaged in the making of unnecessary articles are often required to manufacture some material urgently required for plants that are more directly engaged in war work. The heavy requirements for shipbuilding purposes have made an excessive demand for tubes, and mills are unable to supply the requirements in this particular. Many shipbuilders are unable to operate at full capacity owing to the inability to

obtain an adequate supply of plates. Dealers here would not be surprised to see a stronger position in steel before the middle of the summer. The demand for high speed steel is still quite heavy, and in some cases the supply has been reduced owing to the loss in transit of shipments coming over from England.

### Metals

With the exception of tin the metal situation has developed little of special interest. Shipments are more regular and consumers are better satisfied, but uncertainty still prevails in many respects. Copper is steady with the trade anticipating a revision of prices in the near future. Tin is exceedingly strong owing to the great difficulty in obtaining shipments from the Old Country. Spelter has taken on a better undertone with prices slightly advanced. Lead is steady and unchanged. Antimony is unchanged on a steady demand. Aluminum is in good demand but prices are firm.

Copper.—While considerable interest is still displayed in the prospective advance in the government price of copper the demand from the producers that a better price be fixed for the coming period does not seem to have as many supporters as formerly, and it is not unlikely that any revision in the price will be governed by the supply and the demand. Production at the present time is practically confined to the supplying of the requirements of essential war needs, and should the supply for this purpose be considered ample it may be possible that little alteration will be made in the existing price. However, if production could be increased by a slight advance it is thought that the War Industries Board might consent to the advance. Local dealers are still asking 29 and 30 cents per pound.

Tin.—The proposition of tin is so strong that no transactions but what are absolutely essential are entered into at the present time. The uncertainty of obtaining shipments is more pronounced than ever, and the unsettled condition that prevails in Dutch circles tends to make the market increasingly nervous and acute. Supplies to this country are very irregular, and the consumers are unable to obtain tin even for their most urgent requirements. The market in London is abnormally high, and tin is quoted at £380, an advance in a week of about £20. The situation, however, has a relieving tone, and the early future promises an easier market. Dealers here report a market that is slightly less nervous, but the scarcity of metal tends to maintain the high price; the quotation is still nominal at $1.25 per pound.

### Machine Tools and Supplies

Activity in the machine tool industry has been stimulated by the further placing of shell orders in Canada. Many Canadian firms are now engaged in the making of munitions, and every week additional contracts are being let for the making of shell of various calibre. This development has occasioned considerable interest in machine circles, and much business has resulted, but owing to the fact that many of these firms were working on the British shells, the demand for machinery has not been as great as the amount of the business might indicate, as these firms are adapting much of their former equipment to the making of the new shells. One firm here that has been making machinery for shell purposes has recently received a contract for the making of an 8-inch naval shell, and have taken over additional space and are rapidly fitting the shop with the necessary equipment. The demand for general machine tools is not excessive, but the requirements for all kinds of supplies has shown a noticeable increase during the past week or so. Shipbuilders are good buyers of pneumatic tools and sales of these are very satisfactory.

### Scrap

Transactions in old materials are restricted to immediate requirements owing to the unsettled condition that appears to prevail in this market. The regulations that are imposed on the trading in scrap metals make it very difficult for dealers to base their operations on a profitable footing, so that few are willing to stock or buy more than will satisfy the immediate needs of a customer.

## POINTS IN WEEK'S MARKETING NOTES

**United States Government is likely to go ahead with plant costing $100,000,000 for large projectile manufacture. The arsenal will probably be in the Pittsbury district.**

**Big industrial centres report a shortage of skilled mechanics.**

**Discard steel is being used largely in war purposes, for barb wire posts, etc.**

**United States steel makers are keeping pledge to speed up and devote entire output to war work.**

**Users of pig iron are being requested to state definitely the purposes for which they want orders before they are filled.**

**April production of pig iron in United States was at the rate of 40,400,000 tons a year. This is the highest rate for eleven months.**

**Scrap material is short in United States and Canada, interfering to some extent with the output of steel ingots.**

**Insurance rates have been cut on Atlantic sailings by the U. S. War Risk Insurance Bureau.**

**U. S. officials may inspect Canadian war plants to find solution for delay in turning out ordnance work in U. S. plants.**

**It is estimated that the taking of men of military age from the Sydney mines will cause a drop of 25,000 tons in the output.**

**Mechanics and tool makers are scarce, and as a result U. S. munitions output is only 75 per cent. of what it should be.**

**There is a feeling in steel trade circles that a movement is likely to be made soon in regard to fixing prices in Canada.**

**Canadian buyers of non-ferrous metals claim that upon entering the United States market they frequently have to pay over the fixed price to secure deliveries.**

## LOOKING FOR SOME FORM OF CONTROL

**Steel Dealers Seem to Anticipate Action Will be Taken at Ottawa**

TORONTO, May 16.—War business is still the dominant feature in the market situation this week—new plants, new orders, new tools and supplies. Contracts that are now being secured by some of the largest firms seem to be couched in such a way that they run well into the future, which is somewhat of a contrast to some of those that have been handled in Canada on a month-to-month basis. Big expectations exist in regard to the continuance of munitions business. And in proportion to the increase in this line it will be noticed that domestic lines are cut into more and more. The war rule is put alongside every order that the dealers secure. If the prospective business does not measure up to that standard it receives short shrift. This holds good in United States as well as in Canada.

There is a pronounced tendency among jobbers in Canada who are handling American material exclusively to look for better things after the 1st of July. Just now the warehouse men are dealing pretty much on the stock they have in hand, being unable to replenish it for importing purposes. The warehouse stocks, CANADIAN MACHINERY understands, are none too large, but operations can be kept up for some time on the policy of reciprocity between the dealers concerned.

A peculiar situation comes to the surface every now and then in regard to the United States fixed prices. One Toronto dealer tells of paying 11c a pound above the fixed price for aluminum. The Government is in a position to go in and commandeer the whole supply for its work, but the buyer in Canada does not find himself in any such position.

Scrap dealers say they have very little stock on hand, some going to the point of claiming empty yards. Against this there is the belief that scrap is being

material.

Steel is Firm

plates, although there are always certain fluctuations from the prices set as standards. There is a feeling in the [illegible] of prices. The jobbers think this may come soon, but they agree that it will begin at the mills. There is a marked [illegible] of any product now to go back at once to the [illegible] course is likely to be adopted. Business is being more and more brought within the war scope. Compared with the lines [illegible] nearly all entirely cut off or restricted to the point of stoppage. Even agricultural implements are not given equality with war business in many [illegible]

Some warehouse lines have had a big run. For instance, heavy rounds and [illegible] to Toronto just now. Requirements for the making of dies and punches and other lines where the high speed product is not used has cleaned out these sizes.

Orders that are sanctioned by the Canadian Government and passed on to Washington are coming through in fairly good time, and it looks as though United States were keeping the promise made some time ago to look after the war needs of this country.

### Scrap Metals

One or two rather unimportant price changes have been made this week. Zinc scrap has been bringing $6.50, but is now quoted at $5.50. "There is more prime Western spelter on the market now than I have seen for a long time," stated one Toronto dealer to-day, "and, of course, that has a tendency to flatten out the price of the scrap metal." Scrap zinc, like any other second-hand material, loses in smelting, it being calculated that in the case of zinc scrap some 15 per cent. will come out as dross in the process of recovery.

Although scrap yards are empty, or practically so, prices are not showing an upward tendency. There is some talk of quantities of scrap being held in some quarters, with the idea that a higher price will be paid by the mills owing to the scarcity of pig iron. There is nothing to prove that such is the case, but it is a rumor that prevailed this week.

A decided scarcity of scrap is noticed on the American side, the only plants that have not complained being those with a Bessemer capacity equal to open-hearth capacity. Even such a concern as the Carnegie Steel Co., which has a large Bessemer capacity, is short of scrap metal.

### Demand Big for Tools

Several Toronto firms are finding difficulty in getting machine shops to turn out work that is in excess of their own ability. One of the heads of a plant doing a big munitions business brought out a point that is well worth considering. He put it this way: "The Government, or some central body, should go farther in connection with the controlling of machine shop work and the prevention of overlapping. There are Canadian firms now that are sacrificing their usual lines, on which they will have to depend at the conclusion of the war, because they want to go ahead on war work. By all means get the war work out, but keep up the regular lines as well. Here is an instance. We are going to Montreal to get a shop there to work on a particular machine that is largely used in munitions shops. A Montreal firm is turning out a machine very much the same, and is coming away up here to Galt to get its work done. The result is that there are two plants—the one in Montreal and the one in Galt—doing work for a house in Toronto and one in Montreal. There is a whole lot of wasted energy in it."

Big lathes and boring machines are in [illegible] brisk demand for equipment.

Dealers handling high speed goods report an advance of 10 per cent. on the rather complicated lists that are now used for the purpose of computing values in these lines. For instance, an article that cost $2 85 on the original list, you now add $1.05, then add $1.15, and at the conclusion add 52c. The latest increase applies to cutters only, and includes both the carbon and high speed variety. Tooling up plants for new contracts has caused a big run on high speed.

There seems to be just a little uncertainty in regard to some of the outside business coming to Canada in regard to sizes, frequent small changes, just enough to keep up a little doubt, causing some delay in the completion of the plants being installed to do the work.

### Non-Ferrous Metals

**Copper.**—Dealers here do not look for any change in the price when the new Government ruling takes place at Washington on June 1. It is contended that the present ruling price is sufficient. The agitation for a higher set figure apparently has its origin at the mines, the owners claiming that their returns are not keeping up against the increase in the cost of production. Canadian buyers find no trouble in securing all the copper they need, and this condition seems to be general. This ability to secure needed supplies is counted on to assist in keeping the prices at present levels.

**Aluminum.**—The supply is not great, and dealers can hardly count on securing their needs at the supposedly fixed price. One Toronto buyer, for instance, bought in the American market a few days ago. He paid 11c over the United States price. It is claimed there are cases where the holders will not sell out at the Government schedule.

**Tin.**—Small lots of Chinese tin come through to the local market, but they are uncertain and very high in price. Straits tin used to be counted on for Canadian trade, but that is all under order to the British Government. The price in open market is more in the nature of a bargain between buyer and seller rather than an observance of a fixed price. To-day's figures are from $1.25 to $1.30 per pound.

## TRADE INQUIRIES

THE following inquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained from the Inquiries Branch of the department.

323. Catalogues.—A Port Elizabeth firm of wholesale general merchants requests catalogues and price lists on all lines suitable for the wholesale trade and in a special way on hardware of all kinds, lanterns, cutlery, tools, shovels, enamelware, household utensils, stoves, furniture—knocked down—foodstuffs, wire—baling, fencing, and netting — iron and steel in bars and rods, bolts and nuts, nails, woodenware, stepladders, handcarts, and samples of paper—wrapping and grease-proof—also bags.

324. Catalogues.—A Durban firm of importers requests catalogues on any line suitable for the wholesale general trade, in a special way on hardware of all kinds, tools, axes, shovels, pickaxes, household utensils, iron and steel goods of all kinds.

# SHOULD BE GREAT RECEPTION FOR CANADIAN-MADE GOODS IN EUROPE

Special to CANADIAN MACHINERY.

BRANTFORD, May 14.—George Scott, advertising manager for the Cockshutt Plow Company, recently returned from a business trip in England and France. He had the somewhat interesting experience of being in London when it was visited by the Kaiser's aerial strafers. At the time the most remarkable thing about the occurrence was the lack of excitement on the part of the inhabitants. Either the people had become accustomed to such raids or have become so thoroughly drilled that, to an outsider, the visitation appeared quite as a matter of routine. The unconcern seemed infectious. Not until the raid is over does one wonder at the prevailing indifference.

"What impressed me more than anything," said Mr. Scott, "was the high opinion held in England and France with reference to Canada and things Canadian. In my opinion our prophets are not far wrong when they predict an unusually fine reception for Canadian products in Europe after the war. In view of this it is of course up to Canadians to measure up to the opportunity by showing the same efficiency in the production of the wares of peace as in the implements of war."

# WILL INVESTIGATE CAUSE OF DELAYS

### U. S. Officials May Study Plans That Have Been Followed in Canada

Special to CANADIAN MACHINERY.

WASHINGTON, May 14.—The shipping programme for the United States for the fiscal year of 1919 will call for an estimate of $2,223,835,000. Estimates for this amount have been made to Congress by the United States Shipping Board.

For the cost of construction of ships the Shipping Board has asked for an appropriation of $1,386,100,000 and for the requisitioning of plants and materials $652.000.000. Other estimates are as follows:—For acquisition or establishment of plants for shipbuilding, $5.000,000; lands and buildings, $50.000,000; operation of all ships, $500,000,000; for acquisition of plants for construction of plants for concrete ships, $35,000,000; for recruiting and instructing officers for the American vessels, $10,250,000; for development of port facilities, $25,000.000, and for constructing or completing ships in shipyards for foreign countries, $55,000,000.

#### Rates Have Been Cut

Insurance rates have been cut by the War Risk Insurance Bureau. Because of the diminished danger to Transatlantic shipping a substantial reduction has been made upon the order of Secretary McAdoo on the insurance of hulls and cargoes. The Transatlantic rate has been lowered from 3 per cent. to 2 per cent. A corresponding decrease in the rate of insurance has been made in coastwise shipping. Rates on hulls and cargoes between ports in the United States and the Dominion of Canada have been reduced from ¼ of 1 per cent. to 1/5 of 1 per cent.

#### Investigate Methods

Methods employed by Canadian manufacturers of ordnance will probably be the subject of investigation of a Congressional committee within a short time. Because of the delay in supplying large guns of the American Expeditionary Forces the Senate Committee for Military Affairs has named a sub-committee to investigate the methods pursued in the manufacture of heavy ordnance in the United States. The sub-committee is making a tour of the large steel plants and ordnance factories, and it is probable that Canadian factories will be visited in order that a comparison may be made between the methods used in the Dominion and Canada and the United States.

#### Not Up to Mark

The present output of war munitions in the United States is only 75 per cent. of what it should be, owing to the lack of mechanics and toolmakers, a statement from the United States Employment Service declares. An investigation has just been made under the direction of this organization, and it shows the necessity of taking men from the non-essential industries and placing them in the war trades. An appeal has been made to all manufacturers of non-essentials in the United States asking them to reduce their production in order that the war trades may have a greater labor supply. It is declared that 10,000 mechanics are urgently needed in the war trades. The greatest need for these mechanics is in the Eastern States. Non-essential manufacturers are asked to enrol a reserve list of workers who are willing to take up war work. This reserve list will be made the source of the necessary labor supply.

#### Waste Nothing

Rigid conservation and economy and the use of coal only for essential uses will prevent a coal famine in the United States next winter, according to T. A. Morrow, in charge of distribution for the Federal Fuel Administration. After a conference with fuel producers from the various coal fields, Mr. Morrow stated that efforts have been made to systematize the coal distribution during the summer months so that winter will find sufficient coal for all ordinary purposes. The supply of coal for Canada, however, is presenting a difficult problem, because it involves the very vital question of ships. Because a large number of Great Lakes ships have been put in the Transatlantic trade there is possibility of ship shortage on the Great Lakes. Many ships are also needed at this time to transfer as large quantities of iron ore as possible over the lakes. It is hoped, however, that some arrangement may be made for the use of ships, so that the Canadian coal supplies coming normally from the United States will be transported to Canada during the early summer months. Canadian coal users have been asked to place their orders early and with great care in order that their needed supplies may not be over-estimated.

#### Into War Channels

Despite the fact that the large steel producers of the United States have agreed to turn over their entire output to the Government if its needs demand such action, there is still a limited amount of steel going to commercial users. Estimates made by the War Trade Board here show that the great Government drain on the steel supplies of this country will probably be alleviated within thirty days, and then the normal amount of steel may go to commercial users. Nevertheless the use of steel is being gradually restricted as the war programme of the United States expands. During the past week automobile manufacturers have been called to Washington and asked to prepare a voluntary agreement for the curtailment of the manufacture of pleasure cars. It is estimated here that the Government demands for steel will be about 3,000,000 tons a month. This will be below the normal production, but the margin will be so narrow that there will be restricted supply for commercial users and curtailment of non-essential industries must necessarily follow.

Arrangements are now being made with the producers of pig iron to secure from them a voluntary agreement whereby all of their product will be diverted to war uses.

# COPPER OUTPUT INCREASES IN B.C.

### Big Plans Being Made for the Developments Planned There

The Canada Copper Company, in its annual report, states that at Copper Mountain, B.C., the construction of the new mill has now been entered upon, and that ore reserves of 10,000,000 tons are assured and 2,000,000 tons probable additional were verified by additional underground work. This company has a contract with the Canadian Pacific Railway Company for the construction of a branch line, about fifteen miles in length, from Princeton to Copper Mountain, which will cost about $1,000,000.

# CAPTAIN MICHAEL CHAPMAN KILLED IN ACTION ON THE WESTERN FRONT

On April 25 the death in action of Captain Michael Chapman was announced. He was well known to the machinery and electrical trade in Canada, having been for some years a member of the firm of Chapman & Walker, Ltd., electrical engineers and dealers in machine tools and supplies. This business continued from 1909 until the outbreak of the war in 1914, when Mr. Chapman enlisted, taking his officer's course and getting a commission first as lieutenant, being advanced to the rank of captain afterwards. Deceased came to Canada from England, where he was formerly with Crompton & Co., at Chelmsford, Essex. On coming to this country he was for a time with the Canada Foundry Co., going into business with Mr. Walker at a later date. He was married, and is survived by a widow and two children, the family being in England at the present time.

The late Captain Chapman had been previously wounded in the war, and won the Military Cross for bravery in action during some of the heavy fighting in February. He was with the Grenadier Guards, a regiment to which he was attached shortly after entering the service. Not long ago he wrote to a close friend, part of his letter being as follows: "If I am killed I want you not to fret or mourn for me. It is a fine death for a great cause." Of him the Colonel of the regiment wrote: "The example he set everyone was glorious. He died more than upholding the honor of our great regiment."

## IMMENSE ORDERS STILL POURING IN

U. S. Steel Corporation to Erect Immense Arsenal for Government Work

Special to CANADIAN MACHINERY

NEW YORK, May 13.—Official confirmation has now been given finally to the statements of War and statements of the Board of Directors of the United States Steel Corporation to the effect that CANADIAN MACHINERY that the United States Steel Corporation has undertaken to construct, [illegible] of the Government a mammoth plant to manufacture cannon and projectiles of large size and in great quantities. The official statements do not give the amount to be expended for the Government arsenal, but trade estimates vary from [illegible] Probably one-fourth of this amount will be expended for equipment. It is clearly evident that machinery manufacturers will have orders that will take up their entire capacity for 1919 and 1920. Some of the manufacturers of large tools are already building extensions to be in position to meet the pressing needs of the Government for the manufacture of ordnance, shells, ships, railroad equipment, aircraft and other war munitions. It will be recalled that the great arsenal will probably be built in the Pittsburg district—the official statement says in the Central West.

### One Plant Now

The Steel Corporation is already operating the gun forging plant adjoining the American Bridge Co. at Gary, Ind. Field guns of 155 mm. and howitzers of 9.5 inches calibre are being forged, rough bored and turned at Gary, and the finishing is being done at various Government arsenals. Gun pits of 40 to 50 feet in depth are being provided, and four presses, capable of exerting pressures of 1,000 to 3,000 tons, are being installed.

The latest programme of the Ordnance Bureau of the War Department calls for the expenditure of nearly $1,000,000,000 for projectiles to be delivered in 1919 and early part of 1920. Orders for 50,000,000 75 mm. shells, including shrapnel, anti-aircraft and high explosives, are included in the plans calling for an expenditure of $500,000,000. The programme also calls for 30,000,000 155 mm. shells and a smaller number of 8, 9, and 12-inch projectiles. It is estimated that 6,000,000 to 8,000,000 tons of steel will be required for the manufacture of artillery and projectiles next year. This year's requirements amount to 5,000,000 tons, including 2,500,000 tons for export to the Allies.

### Large Orders Out

In the last week several large contracts for shells have been placed with manufacturers in the Central West, which have been followed by purchases of machine tools and other shop equipment. Among the manufacturers who have received Government contracts for projectiles, hand grenades, aerial shells and depth bombs are the Dodge Manufacturing Co., Mishawaka, Ind.; the L. Wolff Manufacturing Co., and Winslow Bros., Chicago, while the Mosler Safe Co., Hamilton, Ohio, has bought tools in Cincinnati for making gun carriages.

### Labor Shortage Felt

Machine tool builders recently have been hampered by slow deliveries of castings from foundries and by inability to get tool steel promptly from mills, but the main difficulty contended against has been and is the shortage of skilled labor. In New England not a few machines are idle because of the lack of operatives. At Detroit 20,000 to 40,000 skilled mechanics are needed, and a representative of the Navy Department has been conferring with manufacturers regarding an effort to be made to prevent the further drafting of skilled mechanics for the army and navy.

Shipbuilders continue to buy cranes and other machinery to expedite the construction of merchant boats and many new small yards are being started at various points along the Atlantic coast and on the lakes. Among the buyers of machinery in the last week are the New York Shipbuilding Corporation, the Submarine Boat Corporation, and the Todd Shipyards Corporation. The Virginia Shipbuilding Corporation has awarded contracts for a shipbuilding plant on the Potomac River, to cost $5,000,000.

## CONCERNED OVER EFFECT OF TAKING MEN FROM EASTERN COAL AREAS

Special to CANADIAN MACHINERY.

SYDNEY, N.S., May 14.—The coal production of the Nova Scotia collieries for the first four months of the year is between 250,000 and 300,000 tons below the output of the corresponding period of 1917. It appears probable that the production for the half-year ending June 30th will be about 400,000 tons below the first half of 1917.

The effect of the withdrawal of men from the mines between the ages of 19 and 22 cannot exactly be forecast, but in the Sydney district alone it will cause a drop in production of not less than 25,000 tons per month, and it may be very considerably more.

During the first quarter of 1918 the bituminous coal output of the United States is reported to have fallen 2,000,000 tons below the production of the first quarter of 1917 and 3,000,000 tons below the first quarter of 1916. It was stated by Dr. Garfield last winter that the bituminous yield of the United States during 1917 had been 50,000,000 tons below the requirements of the country. The consumption of coal during 1918 will be at a much greater rate than it was during 1917 in proportion to the relatively greater war effort of the United States under the stress of present necessity. War effort may be said to be limited and measured by the production of bituminous coal. With a falling production in the United States, a falling production in Eastern Canada, and a higher rate of consumption in both territories, what may we expect next winter, judging by the experiences of the last? Some increase in production is expected in the Canadian West, but if the increase reaches the most optimistic figures it cannot amount to more than three or four million tons above 1917, and what is that compared with the drop in the United States production?

### Want it Settled

A Royal Commission has been appointed to look into and if possible adjust the differences which have arisen between the Nova Scotia Steel & Coal Co. and its steel workers, and the scope of this Commission's duties have been extended to include the grievances of the Scotia mine workers and the matters at issue between the Dominion Iron & Steel Co. and a portion of that company's workmen. There have been a number of stoppages of work at the mines and steel plant of the Scotia company, but they have been more annoying than serious. The general question of wages at the Scotia company's mines has been complicated by the interjection of a number of small local issues which do not justify any stoppage of work, and which should have been capable of adjustment with much less fuss than has actually been the case. It is hoped that the work of the Royal Commission may have a quietening effect on the irresponsible elements among the unionists. This element is not large, nor important, but it is very vociferous.

## SET NEW RECORD FOR RIVETING

**British Workman Beats Record That Was Set Up in United States**

The record made recently by Charles Schock, who at Baltimore, drove in 2,720 rivets in nine hours, has been beaten in London. The workmen of Frazer and Frazer, engineers and boilermakers, asked the management to give them an opportunity of beating Schock's record, and the effort was made May 7 by a selected squad of riveters under Robert Farrant, aged thirty-one. He is one of a family of eighteen, and his father, aged sixty-seven, is a riveter in the same yard.

The yard set out to do 2,850 rivets in nine hours so as to beat Schock's figures, but Farrant passed that total in six hours. Going on he hammered in 4,267 rivets in nine hours, an average of slightly less than 45 an hour, or one rivet every 7½ seconds. This is claimed to be a world's record.

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5 , 6 and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

# MILLS ARE MAKING A GREAT RECORD NOW

Output Goes Ahead and Faith is Kept With Pledge to The Government

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., May 13. As to [illegible] supplies of commercial steel, the current flows of steel products strike a balance. On the one hand there is [illegible] with the principles laid down by the Director of Steel Supplies at the New York meeting of April 27, that each mill must ship the maximum tonnage possible against the orders of the Government and its allies. On the other hand, production has been increasing and is at a rate better than was expected, a rate well in excess of any previous rate in the history of the industry.

As explained in previous reports, the 100 per cent. effort to fill war orders does not mean that all steel produced goes into that channel, because some of it is not suited. There is some steel left, and a considerable tonnage, indeed, but it in turn must be given most freely to the commercial industries that are most helpful, indirectly, towards winning the war. This distribution the mills definitely undertook several weeks ago. Since then the merchant blast furnaces have undertaken a similar activity in connection with pig iron, but instead of the producers doing this individually, as is the case with the steel mills in distributing commercial steel, the merchant furnaces have gathered data as to the orders on books, and are now gathering data from consumers as to the use they intend for the pig iron they have on order.

### Increased Production

The monthly blast furnace report of the "Iron Age" shows that pig iron was produced in April at the rate of 40,400,000 tons a year. That is the highest rate in eleven months. It is 1,800,000 tons above the average rate in 1917, and 1,000,000 tons above the average rate in 1916, while it is 36 per cent. above the average rate in January and February of this year. That is not the whole story, however, for the rate increased during April and there has been a further increase since, so that it seems fair to estimate that at the present time pig iron is being produced at the rate of fully 42,000,000 tons a year. The increase in pig iron production has been greater than the increase in coke production, on which the production of pig iron has depended right along, the reason for this divergence being that when coke supplies are insufficient the furnaces do not work economically, and consume more coke per ton of pig iron produced. The furnaces now in blast are nearly all working economically at capacity, and further increases in pig iron output will come chiefly from the blowing in of furnaces now idle on account of lack of coke. The best estimate of capacity has been 43,000,000 tons, but there is now a distinct possibility that the furnaces will show they can do more than this.

The spurt in pig iron production, with more coke supplied, is not temporary. The gain will be consolidated by the completion, in the next few months, of several large by-product coking plants, so that there will easily be a large excess of coke-making capacity, and the only danger threatening is traffic difficulties next winter. Doubtless special efforts will be made to accumulate stocks of by-product coal at the by-product ovens and of coke at the blast furnaces.

Steel ingot production has kept pace with increasing pig iron supplies, but the percentage of production to capacity is lower in steel than in pig iron, this being due to the shortage of scrap. The allowance of the scrap dealers' commission of 3½ per cent. a fortnight ago has not increased scrap offerings materially. While the dealers insisted they ought to be allowed the commission in order to make scrap move, they have not made good thus far on their representations. As was thought in many quarters right along, the scrap does not exist, the nature of industrial operations at present not being such as to bring out much old material. The scrap produced in shell manufacture, large as it is, does not entirely fill the gap.

### Discard Steel

A few months ago the brokers were generally able to pick up shell discard steel without much difficulty, and get it rolled into such billet sizes are were required. Now, with a much heavier production of shell steel the discards are much harder to find. The mills had the problem of finding a market for the discard steel, and usually sold it at a shade less than the set prices for ordinary soft steel, but now they are strictly limited as to where they may dispose of the discards. The government has found some war uses for discard steel and is trying to find more. While the material is harder to work, there are many cases where in actual use in war it serves the purpose at least as well as ordinary soft steel. Posts for barb wire entanglements are mentioned in this connection.

### Steel Corporation's Bookings and Shipments

The Steel Corporation's unfilled obligations decreased 314,524 tons during April, against a decrease of 232,049 tons during March. The April decrease was equal to about 24 per cent. of the full capacity for the month, while shipments may be estimated at about 88 per cent. of capacity, from which it would seem the bookings represented about 64 per cent. of capacity. This compares closely with the average of bookings, similarly estimated, for the three preceding months of the year.

While shipments of steel are being rigidly confined to the filling of war orders, when the steel that can be produced fits such orders, it does not follow that the Steel Corporation does not book any additional commercial business. It is the rule with some of the departments to book regular customers for additional tonnages as their old tonnages are worked off. These bookings have nothing to do with the distribution of steel, which is the concern of the government, since the customers are given absolutely no delivery promises. The mills want to serve their regular customers to the extent possible, and they can appraise their prospective requirements the better by having the formal contracts on their books.

### Steel Supply Prospects

To the commercial consumer of steel the present increase in shipments is of particular interest, for the reason that when production was especially restricted the production was as far as possible of war steel, and as the total supply of steel increases a proportionately greater amount of steel cannot be put through the finishing departments that make war material because formerly they were getting more than their proportion of the output. Thus the increased output means, in a sense, a larger surplus of steel that cannot be used in filling war orders. This steel, however, is to be distributed to the industries that will help most in indirect manner, and the success of the buyer in placing an order, or in securing a delivery, depends chiefly upon the use to which he intends to put the steel.

---

## GOOD TRAINING AT START

(Continued from page 523)

of age. "Give me a boy who is full of life, even of devilment around the shop. I always pay a little more attention to that kind, and work with him. I always try to make them see that they are only beginning their real education when they start their trade. They can't become experts without an education. The man with the learning can arrive at a given conclusion ever so much easier than the chap who does his work by thumb-nail plan. When I was able to do so I have bought correspondence school courses for some of the apprentices I was particularly interested in. I read a great deal myself," concluded Mr. Rennie, "but I never get time for fiction. Mechanical and technical papers interest me most of all. I strongly advise the young mechanic to read them."

Mr. Rennie lives at 2156 Gerrard street east, Toronto; is the proud father of a family of twelve—"and never much laid out for doctors' bills, either." He prefers the name "Bill" to William or W. J. or Mr. The Toronto Type have him now in charge of the manufacture of Camco Continuous Feeders, Cleveland Folders, and the new All-Angle Grinder.

---

THE history of the development of the turbo alternator begins about 1889, when a 75-kilowatt machine was built by the Parsons' Company to run at 4,800 revolutions per minute. The first method of cooling turbo alternators by means of radial ducts was that covered by the Brown patents in 1901.

# ECONOMY

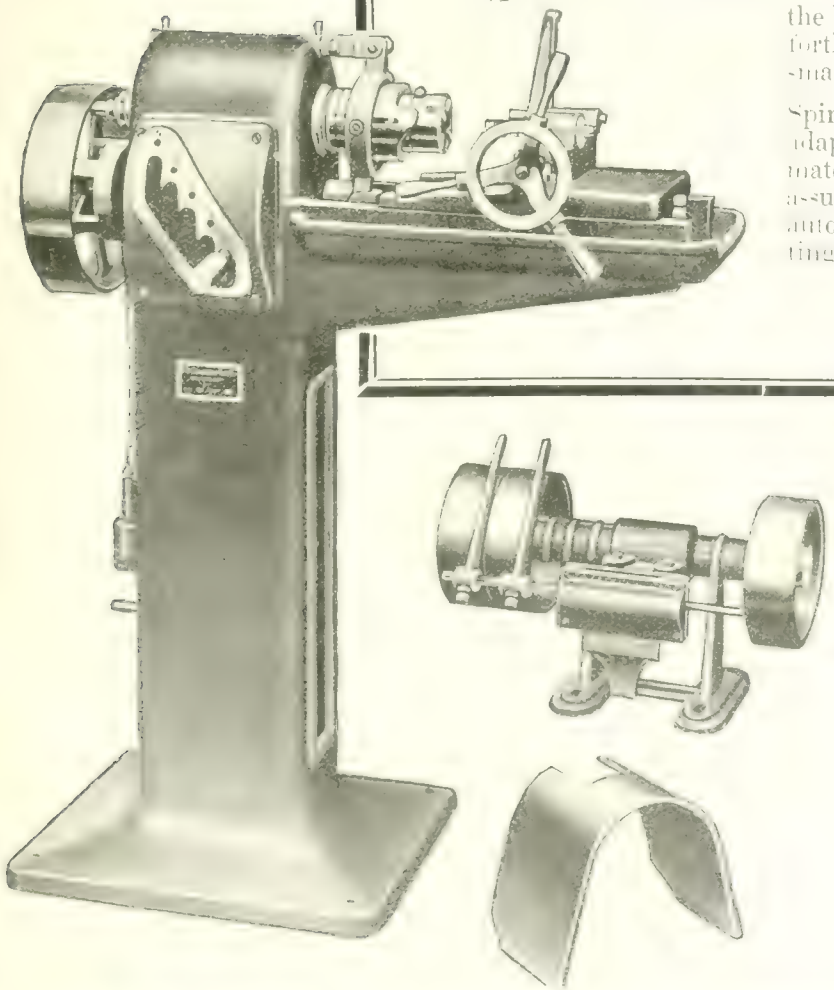
## That is the lesson we are slowly learning

Here is a machine—the Geometric Threading Machine—which has been economizing in screw thread production for a number of years. Busy automatic screw machines cannot profitably be slowed down to cut threads when there is a Geometric Threading Machine at hand. Especially since a Geometric Threading Machine costs one-tenth the price of automatics.

Geometric Threading Machines are employed on a large class of small threaded parts that cannot be produced economically on the ordinary screw machine.

Made in three sizes—to cut ⅛ to ½ inch, ¼ to ¾ inch, and ¾ to 1½ inch diameter threads. The carriage is mounted on slides and on the largest size machine is moved back and forth by rack and pinion, and in the smaller sizes by hand.

Spindle speed changes readily made, adapting the machine to the diameter and material of the work. An adjustable stop assures accurate length of thread, and automatically opens the die head, permitting of drawing the work straight back.



*A line from you brings full details regarding this machine. Tell us your threading requirements — let us recommend the proper Geometric Collapsing Tap or Self-Opening Die.*

Canadian Agents: Williams & Wilson, Limited, Montreal; The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg and St. John, N.B.

# SHIPBUILDING AT POINT WHERE IT WILL OVERTAKE THE SUB LOSSES

[illegible] The [illegible] production [illegible] will pass [illegible] This is [illegible] deliveries for January, February and March. The tonnage delivered was:

| | British Vessels. | United States Vessels. |
|---|---|---|
| | tons. | tons. |
| [illegible] | [illegible] | 19,541 |
| [illegible] | [illegible] | 129,700 |
| March ..... | 242,511 | 166,700 |

The deadweight tonnage delivered in [illegible] was therefore [illegible] March was rather [illegible] but the aggregate tonnage destroyed would probably not exceed 400,000 deadweight tons. In March 54 ships of more than 1,600 tons were sunk, and 27 of less than 1,600 tons. Allowing 4,500 tons as the average of the larger ships, and 1,000 of the smaller, the aggregate gross tonnage sunk is about 270,000. That would be equivalent to 405,000 deadweight tons. A monthly average of 300,000 gross seems to have been calculated upon. Losses reported in April are much lower than in March.

This improvement comes at the eleventh hour. The United States has the task of transporting probably a million men to France in the next few months. The output of ships is rising in American yards, but is below schedule and far below needs. The shipyards of the Motherland, responding to the renewed call, have kept ahead of American production. Every week sees added force gained in the shipyards. Fifty-five days is the record from keel to launching on the Pacific Coast. The obtaining of the services of Charles M. Schwab and Lord Pirrie, the two greatest men in this field in the world, gives hope for a speeding up that will definitely begin building up available tonnage. If the United States is to play its decisive part on the battlefields of France the ships must be forthcoming, and the rising scale of output and diminishing losses afford great hope.

## MARKET FOR MACHINERY AND TOOLS IN ENGLAND

J. E. Ray, Canadian Trade Commissioner at Birmingham, England, reports as follows regarding the possibilities of trade with England in machine tools.

"Although it is practically impossible for Canadian manufacturers to export machinery and tools to the United Kingdom on any appreciable scale at the present time owing to circumstances with which all are familiar, it is evident from correspondence and catalogues recently received at this office that they are anxious to obtain the fullest information possible in preparation for after-war trade. In Birmingham and district are located numerous manufacturers of [illegible] machinery and many kinds of tools; nevertheless, the United States and Germany always maintained large business connections in this area before the war, and the former country has increased its sales enormously during the last three years, particularly in lathes, machinery used in the manufacture of munitions, mechanics' hand tools, saws, hatchets, axes, etc.

"United States manufacturers adopt the policy of appointing agents in Birmingham, who always have stocks on hand, and this procedure appears to be quite satisfactory. Canadian firms anxious to discuss the subject of representation in Birmingham, and who are also prepared to make preliminary investigations with a view to after-war trade, can be introduced to influential houses in this city. Any correspondence on the subject should be accompanied by more than one copy of catalogue. It frequently happens that a single copy is held for some time by an interested firm, and in the meantime [illegible] compelled to await its return. The effect is obvious."

## LICENSES FOR THE EXPORT OF IRON AND STEEL

When making applications for export licenses for iron and steel products listed below, the War Trade Board of Canada request that the following instructions be observed:—

Applicants are cautioned to give the net weight under question 7 and the value under question 8. Under question 10, give date the order was accepted from purchaser abroad.

**Pig-iron.**—Applications covering pig-iron must state grade or quality. File on form X-2.

**Billets, blooms, ingots, slabs, shapes, sheet bars.**—State whether steel is Bessemer or open hearth. File on Form X-2.

Separate applications required for each of the following commodities:

**Alloy and high-speed steel and tool steel.**—Applications covering alloy and high-speed steel must show percentages of alloys therein. File on form X-2. If crucible or open hearth steel containing no alloy except manganese under 2 per cent. specify on application "not alloy steel" and file on form X only.

**Bars.** State whether Bessemer or open hearth. Applicants for round and square bars must state "under 2½ inches" or "2½ inches and larger." Make separate application for round and square bars 2⅛ inches and larger. File on form X-2.

Round and square bars under 2½ inches and flat bars. File on form X only. State maximum width of flat bars.

**Boiler tubes.**—Applications covering boiler tubes must specify whether "cold drawn seamless," "hot rolled seamless," "lap-welded steel," or "charcoal iron. File on for X-2.

**Fabricated structural steel.**—When applying for fabricated structural steel (punches, riveted, etc.), state approximate percentage of plates therein, and if only connection plates are used, so state. Also whether plates are "under ⅛ inch" or "⅛ inch and heavier." File on form X-2.

**Ferro-silicon, spiegeleisen, skelp, scrap, mechanical, seamless, tubing, oil-well casing, drive pipe.** File on form X-2.

**Plates (iron and steel).**—⅛ inch thick and heavier. Make separate application for plates wider than 72 inches and file three copies of specification. File on form X-2.

**Pipe (wrought iron and steel).**—Black or galvanized. Applications must state whether "under six inches," or "six inches and over" (inside diameter). Six inches and over, file on for X-2; under 6 inches, file on form X only.

**Pipe (cast iron).**—State tonnage of each size. File on form X-2.

**Rails.**—State if new or second-hand and weight per yard. Make separate application for rails 50 pounds per yard and heavier. State whether Bessemer or open hearth. File on form X-2.

**Sheets.**—Applications covering black and galvanized sheets under ⅛ inch thick must specify gauges. State whether Bessemer or open hearth. File on form X only.

**Wire.**—One copy of specifications in detail, showing sizes, must accompany all applications for wire of gauges lighter than, or equivalent to the following: American steel and wire gauge No. 17. Birmingham wire gauge No. 17. Paris wire gauge No. 7. File on form X.

**Wire rope or cable.**—Applications covering wire rope or cable must specify quality and construction. File on form X-2.

Other items not mentioned above are to be filed on form X.

Failure to file applications in accordance with the above may result in refusal of export licenses.

## EXPORT OF PLATINUM FROM CANADA TO THE UNITED STATES

The following regulations to be observed when submitting applications for the export of platinum from Canada to the United States have been issued by the War Trade Board of Canada under date April 26, 1918:—

Applications for export license from Canada must be accompanied by:

(1) United States import license.

(2) Application for United States export license for equivalent quantity from the United States.

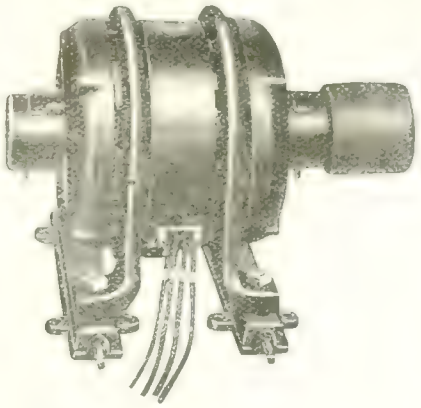
(3) Undertaking by Canadian importer to produce evidence within sixty days from the granting of Canadian export license to the War Trade Board, Ottawa, that an equivalent quantity of platinum has actually been imported.

# Aikenhead's "AK" MOTORS

The A. K. stands out about above all other motors for smooth-running and efficiency.

**Aikenhead Hardware Limited**

**17, 19, 21 Temperance Street TORONTO, CAN.**



The North Western Electric Co., of Chicago, are the makers of A.K. Motors—a name that stands for all that is modern and best in motors.

The A.K. has a constant speed induction motor in 2 or 3 phase, 25, 30 and 60 cycles.

Aikenhead's carry the following A.K. Motors in stock: 25 cycle in 1, 2, 3, 5 and 7½ H.P.; 1470 R.P.M. 25 cycle in 1, 2, 3, and 5 H.P.; 735 R.P.M.

**Write us for A.K. Motor Facts.**

# Aikenhead's Wahlstrom

It has neither collets, sockets nor keys, and is undoubtedly the strongest, fastest positive drive automatic chuck for drilling, reaming, tapping and counterboring.

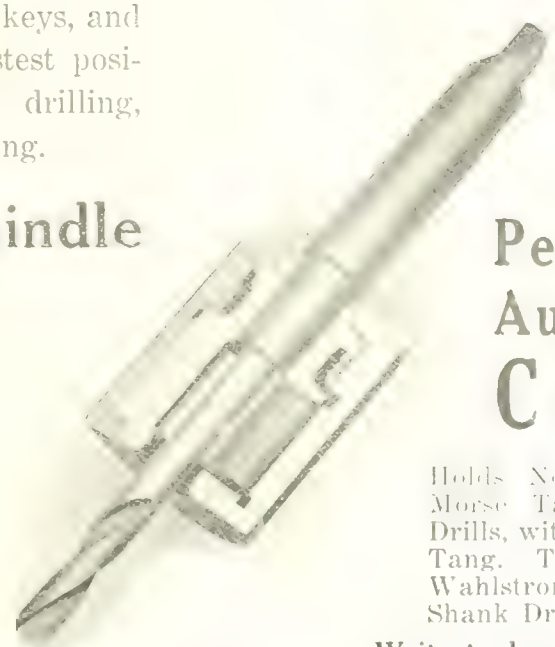
## You Don't Stop Spindle

And waste minutes putting in or taking out the drill. In just two seconds you make tool changes, the Wahlstrom perfectly centering the tool automatically.

**Aikenhead Hardware Ltd.**

**17, 19, 21 Temperance Street**

**TORONTO, CAN**



## The Perfected Automatic Chuck

Holds No. 1, 2 or 3 Morse Taper Shank Drills, with or without a Tang. There's also a Wahlstrom for Straight Shank Drills.

**Write to-day for Catalog.**

# INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

## ELECTRICAL

Toronto.—The extent to which consumption of electricity has increased in [illegible] Ontario served from Niagara Falls may be [illegible] by municipalities served from the Niagara [illegible] of the Hydro-Electric Power Commission of Ontario. When the commission was initiating its operations, the late Premier, Sir James Whitney, a staunch supporter of the project, stated to Sir Adam Beck, that the commission would not require 10,000 h.p. The commission now serves over 121,000 customers, of whom 117,000 are light and 4,000 are power consumers. It supplies over 200 municipalities, and operates about 3,000 miles of transmission lines. In short, over half the population of Ontario is supplied with electricity through its agency. Its contracts with municipalities for the August, 1917, load totalled about 159,000 h.p., [illegible] December, 1917, load was estimated at about 201,000 h.p. The present available supply of power for the 200 municipalities served by the Hydro-Electric Commission is exhausted. The shortage is acute.

## MUNICIPAL

**Aylmer, Ont.**—The town is consider[illegible]

**Hamilton.**—The city is considering putting in a six-inch water main on Hunt street.

**Leamington.**—The council is working on plans for the erection of a water reservoir having a capacity of 1,200,000 gallons.

**Port Dover, Ont.** Tenders will be called about June 10 or 15 for the erection of a swing bridge, costing between $15,000 and $20,000, for the town council [illegible]

**Markdale.**—A meeting held the other evening, addressed by Deputy Fire Marshal Pointon, of Toronto, brought in recommendations for more adequate fire protection for Markdale. The fire tower will be heightened; 500 feet of hose will be secured, reel and ladder will be se[illegible] [illegible] provided.

**Ullsonburg.** The by-law to cancel a [illegible] and to guarantee $25,000 bonds on the Huntley Manufacturing Company, Limited, was carried by a majority of 401 votes. The company's plant was destroyed by fire in March, and it received many tempting offers from outside points. It will erect a modern factory building at once, 120 by 180 feet, to employ about 75 skilled mechanics.

**Trenton.**—Trenton ratepayers endorsed two money bylaws, one for $16,000 to install modern fire-fighting apparatus, including a new motor fire engine and chemical extinguisher, the other for $21,000 to purchase a waterworks system from the Hydro-Electric Commission of Ontario, who acquired it from Seymour Power and Light Co., when that concern was absorbed by the Hydro. Both bylaws were carried by large majority in heaviest poll ever registered on money bylaws in Trenton.

**Hamilton.**—The local fuel administrator has secured the cancellation of the order keeping down fuel purchases to 70 per cent. of the amount needed up to March 31, 1919. City Clerk Kent had always contended that such a restriction would be more harmful than beneficial, pointing out that only the midsummer and fall purchases last year saved the local situation, which was sufficiently acute to occasion alarm. Early in the week, he persuaded the Board of Control to petition for the suspension of this paragraph of the regulations, and the provincial fuel administrator lost no time in complying. Householders are now permitted to lay in as much coal as they can get.

## PERSONAL

**G. Barrett**, formerly of Chatham, has gone to the Quinlan & Robertson, Ltd., shop at Campbellford, Ont., where he takes the position of general superintendent.

**J. A. S. Germain** has resigned his position as secretary-treasurer of the Canada Stove and Foundry Co., and has opened an office as manufacturers' agent at 104 Delorimier Ave., Montreal.

**J. A. St. Germain**, for the past twelve years secretary-treasurer of the Canada Stove and Foundry Co. of St. Laurent, has severed his connection with that firm, and has opened an office in the old Montreal office of the above company. The Canada Stove will have no connection with the new office, but Mr. St. Germain will continue to handle all their lines, in addition to a general agency for other lines of manufactured articles, principally relating to hardware.

**Capt. N. Marin**, of Port Arthur, died suddenly at Kingston after a couple of hours' illness of heart failure. He arrived with the tug Laura Grace from the head of the lakes for the M. T. Co., and was to have remained here for the summer with that company. He was aged 65 and was well known in marine circles. He is survived by a grown-up family.

## TRADE GOSSIP

**Lightning Started Fire.**—Started by a bolt of lightning, fire destroyed the Alvinston flax mill on May 10 at a loss of approximately $10,000. It was owned by McCaull Brothers, of Petrolea.

**Busy at Galt.**—The Galt Brass Co. will erect an addition 114 x 164 feet to their plant and the R. McDougall Co. will add a three-storey building 120 x 64 feet to their factory.

**Making Extension.**—The Canadian Machinery Corporation is completing a new assembling room, about 200 feet square. A dance on the evening of the 17th inst. will mark the opening of the building.

**Selling Out Plant.**—Notices are appearing announcing the sale of the property and machinery of the Quebec Ammunition Co., Ltd., 112 St. Patrick Street, Montreal. Wilson & Motherwell, 232 St. James Street, Montreal, are the liquidators.

**Have Big Orders.**—An order for $2,500,000 of shells for the United States has been placed with the Dominion Forgings and Steel Company of Hamilton, and other orders are expected in the future. This is one of a number of steel orders which are coming to Canada.

**To Develop Power.**—North Vancouver contemplates the purchase of power site of the Naire Falls Power Co. The figure will be approximately $75,000. The idea is to secure a supply for the domestic lighting and heating of Greater Vancouver.

**Want More Money.**—Brantford machinists are demanding recognition of a new wage schedule calling for 55 cents per hour for toolmakers and journeymen and 45 cents per hour for improvers. The matter will probably be referred to a board of arbitration.

**Blames the Company.**—A coroner's jury, empanelled to enquire into the death of Alfred W. Ingram, Harry Sylvester and George Cameron, employees of the Hamilton Tar & Ammonia Works

# Advantages in Using the Almond Line of Chucks?

Almond Chucks are powerful, accurate and durable, and they cost less to operate than other chucks. This is one big advantage in using them.

## *Quick Deliveries*

We are well equipped to quickly fill your requirements for all sizes of Drill Chucks, and the smaller sizes of Lathe Chucks —5″, 6″, 7½″ and 9″. This is another important advantage you get in adopting Almond Chucks.

Almond Service saves time and money. Specify Almond in your next order—especially if it needs filling in a hurry.

143 University Ave., Toronto, Ont.

Co., Hamilton, who were killed in an explosion, found that the company was to blame for not taking the proper precaution in having the ammonia tank which caused the fatality regularly inspected, or the pressure therein gauged.

**Business Change.** — The Canadian Welding Works, Limited, has taken over the business of the Dominion Architectural Iron Works, Limited, and will move into the premises of the latter immediately. The Canadian Welding Works will continue to carry on the work previously done by the Dominion Iron Works, and will also enlarge on their present business. The location of the new factory will be at 175 McCord street, Montreal.

**Twenty Quebec Bridges.**—"The steel that Canada has made up into shells since the outbreak of the war would be sufficient to build the Quebec bridge twenty times," says ex-Commissioner Chalmers, at Edmonton, now an inspector under the Government Munitions Board. He says that shell-making is being well maintained in the Dominion, although some of the plants had gone out of action, this being due to the fact that a different size was asked for and some of the plants did not care to go to the length of adapting their equipments to the changed requirements.

**New Plant Rushed.**—An American company, represented in Toronto by the Holden-Morgan Company, has purchased three and three-quarters acres in Ward One as a site for a large ammunition factory. It is claimed that the company will work on the largest ammunition contract ever awarded in Canada, and will manufacture shells, which are larger than any heretofore turned out in the Dominion. The factory has to be erected and in working order within sixty days, and a staff of several hundred men are working night and day to accomplish it. The site of the new factory is a part of the Wm. Harris estate, and the sale was arranged through Pearson Brothers, local real estate dealers.

**Toronto Man's Idea.**—One of the most promising improvements upon the modern airplane which inventive genius has recently devised is the product of the brain of Lloyd Lott, for a short time with the Sheet Metals Products Co., Toronto. Mr. Lott's invention is a detachable fuel tank for airplanes, the moving of a lever throwing the gasoline tank clear of the machine, whatever its position or angle. It is estimated that 75 to 85 per cent. of aerial mishaps in active service are due to fire and explosion. The new device is in the nature of insurance against such accidents. While cutting off the tank, it provides for the feeding of the engine for a sufficient time for safe descent from an emergency receptacle.

**The Annual Meeting.**—The stockholders of the Joseph Dixon Crucible Company held their annual and regular meetings on Monday, April 15. The following directors and officers were elected:—Directors, George T. Smith, William G. Bumsted, J. H. Schermerhorn, George E. Long, Edward L. Young, Harry Dailey and Robt. E. Jennings. Officers—George T. Smith, president; George E. Long, vice-president; J. H. Schermerhorn, vice-president; Harry Dailey, secretary; William Koester, treasurer; Albert Norris, assistant secretary and assistant treasurer. Of the 20,000 shares of stock, 19 379 were voted. Undoubtedly a greater number would have been voted had it not been that a number of shares are held by estates, the executors of which do not feel at liberty to vote in an election. The report made by President Smith and the remarks made by him on the business of the company were received by the large number of stockholders present as most satisfactory and pleasing in every way. The American Graphite Company, incorporated under the laws of the State of New York, is a subsidiary of the Joseph Dixon Crucible Company, and its anuual election was held on the same day as that of the Joseph Dixon Crucible Company's, and resulted in the election of the following officers:—George T. Smith, president; George E. Long, vice-president; J. H. Schermerhorn, treasurer; Harry Dailey, secretary. The directorate is the same as that of the Joseph Dixon Crucible Company.

## TENDERS

**Will Build.**—Grace Church, Brantford, will likely erect a Sunday school building and parish hall, to cost about £35.000.

**Edmonton.**—The Merchants Bank of Canada are getting out plans for a $50,000 addition to their building on Jasper avenue.

**Calgary, Alta.**—The Alberta Flour Mills, Ltd., 816 First St. West, are receiving prices for reinforcing and structural steel in connection with the erection of their flour mill to cost $1,500,000. A. Ingram is the engineer.

**Toronto.**—In connection with the erection of $95,000 Childs Co. restaurant on Yonge street, at the corner of Dundas East, Bennett & Wright, 72 Queen E., have the wiring and A. Matthews, Ltd, 256 Adelaide St. W., the roofing contract.

**Toronto.**—Sealed tenders will be received up to 12 o'clock noon of Monday, May 20th, 1918, for the construction of a concrete and stone ford over the Etobicoke River on the grounds of the Toronto Golf Club, Long Branch, Ont. Frank Barber, engineer. Plans and specifications may be seen at 40 Jarvis street, Toronto.

**Rebuilding Halifax.**—Tenders are being called for repairs to "Bloomfield" High School, costing $36 000; repairs to "Chebucto" school, costing $25,000; repairs to "Joseph Howe" school, costing $35 000; repairs to "St. Patrick's" Boys' School, and repairs to "St. Patrick's" Girls' School for the School Board. 81 Sackville St. Clerk S. J. Wilson, 81 Sackville St.

**Windsor, Que.**—Sealed tenders will be received until noon, May 25th, 1918, for the re-construction in cement of two

piers of the Windsor and Brompton Bridge, crossing the River St. Francis, between the municipalities of the town of Windsor and of the parish of St. Francois Xavier de Brompton. J. A. Lagasse, N.P., sec.-treasurer of the Windsor and Brompton Bridge Committee, Windsor, Que., Co. Richmond.

**Walkerton.**—Tenders will be received by the undersigned up to the 25th day of May instant, inclusive, for the construction of a concrete dam between 180 and 210 feet long, to replace the Saugeen Electric Light and Power Co,. Ltd., former wooden dam across part of the Saugeen River on the Company's mill property at Southampton, to connect with the concrete dam already erected thereon, and for the doing of certain excavation, filling and other work connected therewith. Plans and specifications may be seen at the Company's office at Walkerton, Ontario.

**Ottawa.**—Tenders for Dominion Government office buildings, Ottawa, will be received until 4 p.m. on Monday, May 27, 1918, for the construction of a Dominion Government office building, O'Connor street. Ottawa, Ont. Note.—Blue prints can be obtained at the office of the Chief Architect, Department of Public Works, by depositing an accepted bank cheque for the sum of $50, made payable to the order of the Honorable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid. R. C. Desrochers, secretary, Ottawa, May 7, 1918.

## MARINE

**Vancouver.**—The Faith, the world's largest concrete steamer, and the latest innovation in the ocean-carrying trade, which completed its trial trip at San Francisco a few days ago, will make its first ocean voyage from California to Vancouver with a load of salt.

**Collingwood.**—Another new steamer has been launched at the yards of the Collingwood Shipbuilding Company here. The vessel is of the poop, bridge and forecastle type, with engines amidships, and her dimensions are: 261 feet overall, 251 feet b.p., 43 feet 6 in. beam, 20 feet depth moulded, and she will carry approximately 2,900 tons deadweight.

**Quebec.**—Three vessels launched within three days, such is the record of old Quebec. Two vessels, both built of steel, at the Davis shipbuilding plant, at Lauzon, have been launched and one wooden vessel. A large wooden vessel built at the Quinlan and Robertson yards on the St. Charles River will be launched. More vessels are on the ways at the various shipyards about Quebec.

**Hamilton.**—At the last meeting of the Board of Trade, G. E. Main submitted a list of 120 shipbuilding concerns doing business in Canada, and stated that Hamilton was particularly well situated for this class of industry, both on account of its harbor and dockage facilities, and its nearness to the Welland Canal. He suggested that an effort be made to se-

# A Much Better Outlook for the Allies

"LLOYD GEORGE is now secure. The whole Empire is overwhelmingly behind him, as is France with Clemenceau. Wilson, by calling in more of the biggest men in America, and fearlessly dealing with the incompetency that is unavoidable in any new organizations, no matter how efficient be the general management, is rapidly building an army with its resources that will ensure a successful termination of the war."

### An Auspicious Issue

These heartening words are from the front page of THE FINANCIAL POST of May 11th. They are contained in an editorial by Col. J. B. Maclean, whose vigorous words on every phase of the war have been pregnant with truth. They come with added force from a Canadian business point of view in the Trust and Loan Number of THE FINANCIAL POST, an issue which gives present conditions in this field fully and clearly, and which points with certainty to factors bearing on conditions to be expected in the future. To have this week's issue of THE POST by you is to be fortified with information of the utmost value in the conduct of business in Canada.

[illegible] of this nature for Hamilton.

**Quebec.**—It is learned on good authority that Chief Justice Dorion of Ottawa has granted exemption from military service to all the shipyard employees working on shipbuilding at the Davie yards at Lauzon, Que. It was agreed that should the draftees working at the yards be enlisted their leaving would deprive various departments of experienced men and the entire plant would have been hurt. Mr. Davis, however, was told not to enlist any more men of military age.

**Owen Sound.**—According to latest reports, it is the intention of the government to offer for sale the steamer La Canadienne, which has wintered in Owen Sound harbor for a number of years past. The La Canadienne was formerly engaged in lake survey work. She is a steel vessel about 165 feet in length, with 27 feet beam and 11 feet depth. Should the Department decide to offer the boat for sale, it would be a good opportunity for Georgian Bay shippers to get a good package freighter, even though her passenger capacity would be limited.

**Cleveland.**—The log jam is still on at the head of the lakes. Fourteen cargoes were floated at Duluth on May 9 and 29 vessels were lined up at the docks. It will take two days to clean up the waiting fleet. Carriers as a rule are being worked out in from 24 to 30 hours, but in some cases boats have been held three days. A steady improvement in despatch is looked for, but it will be a week or more before loading is good all around. Receipts are more liberal at Lake Erie ports, and there will be a good-sized fleet at this end of the route the first of the week. The grain movement is not heavy enough to cut any figure, and that trade is not taking care of much tonnage.

**Toronto.**—Complying with the order of the Minister of Marine almost every Canadian vessel on fresh water has been fitted out with the new life preserver recently adopted by the department. The change has cost the larger lines a considerable amount of money. In many cases the old life preservers were left intact on the vessels, while others have discarded them. Final notice to steamboat owners who had not as yet equipped their vessels with them reached local vesselmen last Saturday. Some ten thousands will be required to equip the steamers of the Toronto Ferry Company. The number necessary to equip the local excursion and tourist steamers is well up in the thousands.

## INCORPORATIONS

**Standard Electric and Acetylene Welding Co.,** has been incorporated at Montreal, to carry on the business of iron and brass founders, mechanical engineers, tool makers, etc. Capital, $10,000.

Incorporation is granted to the Perfection Mfg. Co., to make, buy, sell, lease and deal in agricultural, creamery, cheese factory, dairy and farm machinery, etc. Capital $100,000, and head office in Montreal.

**Beaver Stamping Co.** has been incorporated at Ottawa with a capital of $40,000 to manufacture metal stampings at Walkerville, Ont. The incorporators are R. T. Herdegen, P. Wells and B. F. Kiesel, all of Detroit, Mich.

**The Interprovincial Mfg. Co.,** Montreal, has been incorporated, with a capital stock of $200,000, by Edouard F. Surveyer, William L. Bons, E. M. Silver and others, to manufacture automobile bodies, caskets, carriages, machinery, etc.

**Dodd Heating Systems Ltd.,** has been incorporated at Ottawa with a capital of $100,000 to manufacture heating, lighting and power appliances and apparatus, etc. at Toronto. The incorporators are John O'Neil, H. S. Dodd and J. Sheedy, all of Toronto.

**The Manitoba Bridge & Iron Works, Ltd.,** Winnipeg, has been incorporated, with a capital stock of $1,000,000, by Thomas R. Deacon, president and general manager; Hugh B. Lyall, secretary, and others, to take over the company of the same name.

**Shand Engineering and Contracting Co.** has been incorporated at Toronto with a capital of $40,000 to carry on the business of engineers and contractors at Sault Ste. Marie, Ont. The provisional directors are James Shand, S. P. West and G. W. Goodwin of Sault Ste Marie.

**Canadian Graton & Knight, Ltd.** has been incorporated at Ottawa by R. H. Jackson, F. P. Brais and J. Bruneau, all of Montreal, to manufacture leather belting and leather sundries of all kinds. The capital stock is $100,000 and the chief place of business is Montreal.

**New Incorporations.**—Joint stock companies incorporated include the following: Zimmerman Manufacturing Company, Limited, Hamilton, capital $1,000,000; Perfection Manufacturing Company, Limited, Montreal, capital $100,000; Webster Motors, Limited, Sherbrooke, capital $75,000; the Perfect Shoe Company, Limited, Montreal, capital $50,000; Prest-o-lite Company of Canada, Limited, Toronto, capital $800,000; Homes Foundry Company, Limited, Sarnia, capital $500,000.

**The Canadian Forging and Socket Co.** last week was granted a charter to do business in Canada, with a capital of $250,000, and expects to open in the building formerly occupied by the F. S. Carr Co., at Tilbury, Ont., as soon as the preliminaries can be arranged. The incorporators are:—E. J. Beattie, Detroit; W. J. McKenzie, Pontiac, Mich.; Gerald McHugh, of Windsor; James Foster and E. G. Odette, of Tilbury. The company proposes to engage in the manufacture of munitions.

**Holmes Foundry Co., Ltd.,** has been incorporated to make, buy, sell and deal in goods, wares and merchandise and property of all kinds, and without limiting the generality of the foregoing in steel, iron, brass and aluminum products; to carry on the trades and business of iron masters, iron founders or smelters,

and of manufacturers and rollers of steel and iron into any and all forms, etc. The share capital is $500,000, and the head office and place of business is at Sarnia, Ont.

**Prest-O-Lite Co.**, is incorporated to make, produce, deal in, etc., materials of every kind employed in the producing or generating of acetylene and other gases; also to generate, produce, use, purchase and sell or otherwise deal or traffic in acetylene and other gases in portable cylinders, and to manufacture, produce, use, purchase and sell or otherwise deal or traffic in all machinery, apparatus, appliances and fixtures for any purposes relating in any manner to the production, use and distribution of acetylene and other gases.

**To Develop Peat.**—In this week's "Gazette" announcement is made of the incorporation of the National Peat, Limited, with a capital of $100,000. The purposes of the company, as set forth in its charter, are: to carry on the business of treating, refining, concentrating, mining, excavating, reducing, precipitating, analyzing, manufacturing, buying and selling peat and all by-products thereof. The provisional directors of the company are: Edward Lindsey Middleton, Albert Edward Knox, Frances Morrow, Thomas Louis Monahan and Florina Berrini.

## CATALOGUES

**The Link-Belt Co.** have issued a book regarding their silent chain drive. Besides dealing technically with the value of the product, the book is illustrated profusely. It shows the chain belt in use in many operations, doing work on machines running many revolutions per minute, and on others where great wear and tension is constantly applied to the drive.

The Armstrong Cork & Insulation Co., of Pittsburgh, Pa., have issued a little booklet, "Satisfaction or ———." It deals with the importance of having drinking water systems established in industrial plants, claiming that in this way, by attending to details, a firm will be able to keep its employees for longer periods, and reduce the hiring and firing troubles.

The Ready Tool Co., Bridgeport, Conn., have just published their Quick Reference Catalogue No. 16. This catalogue illustrates and describes their chrome nickel lathe tools with the tool steel bearing; shaper and planer tools; tool holder for bench and watch lathes, which is the smallest tool holder on the market; boring tool holders; boring bars and internal threading tools; cutting off tools; threading tools; side tools; shaper or milling machine vise hold downs; lathe dogs; milling machine dogs; tail grinder dogs; balanced grinder dogs; handy holders; the Hill holdback dog; belt sticks; high speed steel cutters; and lastly, a price list of extra cutters. This catalogue, which is small enough to be carried around in one's lower vest pocket, will be sent to any reader of this publication upon request.

Lanco Balata Belting

[illegible] one of the most expensive items on the market.

When the cost of raw material increased the price of the belt to where it is to-day, we were a little afraid that it would result in a diminution [illegible]. We have been very agreeably disappointed the sales have not dropped off.

There are cheaper belts on the market that will give a good service but not for as long. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the plies tightly together, is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that as far as we know has never been equalled by any other gum. The duck is of course stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions except those of heat it will give a length of service that makes its price worth while.

# Pattern Making: Economical and Efficient Methods

By M. H. Potter

*The pattern is in many cases the connecting link between the engineering department and the manufacturing departments of an industrial plant and consequently important to the accomplishment of plant processes, which enhance the pattern shop's importance and call for the best judgment in the choice of methods.*

ONE of the first places in which to begin the work of economy and efficiency is the pattern shop. In most instances this department offers more opportunity than the machine shop or assembling and designing departments. As a matter of fact this department has been somewhat overlooked and naturally the methods of procedure can be greatly improved upon.

The workmanship should be kept to a high standard, the lumber used of course depending upon the number of times the pattern is to be used; patterns from which few castings are to be made can be produced from a second grade lumber and with a little less labor in their construction. Any patterns made for constant use should be of the better grades of pattern lumber. Patterns which are to be used but once can be cheaply made. The lower grades of white pine is good enough for cheap patterns and pine of the better quality is adapted to the better patterns. Mahogany is used to advantage in making small size patterns and in facing larger patterns.

### Principal Points

The proper allowances for machining and shrinkage should be given careful attention. In order to prevent unnecessary cost due to machining and finishing the pattern must receive consideration. Although changes can be made in the pattern after a casting has been machined such alterations are expensive and by the proper forethought can be avoided. As a rule the draftsman is not familiar with all the conditions in the foundry and machine shop. It is up to the pattern maker to recommend and make such changes as will effect a decrease in the cost of moulding or machining or produce a better casting. Unnecessary expense can in this way be saved by inspection before proceeding with the work in hand.

Cheap patterns should not be classed as those made by inexperienced workmen but rather those which are intended for limited use and will only go to the foundry once or twice. Instances have occurred where the foundry when given a contract to produce a number of castings from patterns furnished have found it cheaper not to use the patterns supplied but to make up new patterns which would permit of not only quicker moulding but less castings. All this must be taken into consideration, as it is in the early stages of the work that great savings can be effected.

Such opportunities for saving in this particular department have led many of the larger and more progressive manufacturers to assign one employee to this work and by his efforts endeavor to eliminate the waste of time and materials in incorrect pattern making. He must not only be familiar with the most advanced methods of pattern making, molding and machining, but also in close contact with the design and requirements of the product. A man of such knowledge, provided he is one with practical experience, will effect not only a saving in time and labor but also delay. A proper uniformity of castings will be secured, and unnecessary stock, meaning a reduction in weight, and correct designs will prevail. The loss of castings due to cracking, which causes a delay in production will be practically eliminated, as most any of the ordinary troubles can be avoided by proper supervision in the pattern shop.

### Checking

The checking of patterns by the drafting department is something that should always be done; although this is ordinary routine in any large shop, many of the smaller ones do not adhere to it strictly. The only practical way to determine as to whether or not the proper allowances have been made to produce the desired casting is to carefully check the pattern. If this is not done the pattern maker soon becomes aware of the fact, and knowing that his work is not checked soon becomes careless. A careful inspection of the pattern before it goes to the foundry will expose any weakness in the design and thus save a loss in the foundry. It will enable the foundry to produce a more perfect casting at a lower cost. Many minor details in the design which would increase

FORM 2.

castings may not turn out as expected and the pattern wil be redesigned. It is best therefore especially on work in connection with a new design, to limit the outlay as much as possible until it is determined that the results are satisfactory. A considerable amount of knowledge is required in most cases to tell from a drawing as to which is the best way to undertake the work. When a man of such skill can be secured his salary is a secondary consideration, as he is in a position to effect a great saving of both time, labor and delays.

Many manufacturers of a stock product rely upon interchangeability to secure economy and eliminate complications. The various parts of the pattern, whenever practical, are made so as to be interchangeable. In core making particularly is a great saving made.

### Machine Equipment

Special labor-saving machinery is another great help to the pattern maker and a cost decreasing element. In fact labor-saving machinery of this type is practicall yessential; without it patterns cannot be made in an economical way. Its use enables boys at a low rate to turn out first class, satisfactory work in less time than the experienced pattern maker working by hand can do it. Of course, such help requires a certain amount of training and familiarity with the various machines used. The up-to-date pattern shop has its special machine tool equipment the same as the tool room or the machine shop, that is if reduced labor costs are an important requirement.

In order to secure good results and prevent delays the foreman pattern maker and the inspector must keep in close touch with the drafting, foundry and machine shop departments. This co-operation will enable them to know exactly what results are being obtained and where the trouble and delays are. Success cannot be attained to any great extent unless this is made a practice of. By seeing the results of his work the pattern foreman is enabled to shape his endeavors and those of his department to secure the results wanted. On the other hand the inspector is in a like position and can do away with the repetition of errors and delays. This is especially true in shops employing a majority of unskilled help and depending upon the special machine equipment to make up the deficiency.

### Routine Forms

A pattern requisition form as illustrated in Fig. 1 or a similar form has found favor with a number of concerns. It is self-explanatory is made out in part (material to be used and grade) by the pattern inspector. By this method no unnecessary expense is made in patterns.

The material and labor cost form shown in Fig 2 is essential; by referring to same the accounting department can determine the actual cost of the pattern. The symbol number is the machine or apparatus number to which it is a part.

Although the pattern record form is of minor detail, see Fig. 3, it enables the interested party or department to know exactly how many times the pattern has been to the foundry, the number of castings made, the condition and the repair work necessary. It also enables immediate location in case of alteration or inspection. As any other records are valuable for reference, for fixing costs and estimating purpose, so are these pattern records which are easily kept at no great cost.

While red tape is far remote from most pattern shops, the introduction of a certain amount of system and supervision would not be wasted in this particular department. Especially when the underlying principles and elements mean so much to the results finally secured and the costs involved.

A close investigation of many pattern making departments in well managed and seemingly efficient organizations would no doubt make certain the fact that should the patterns be purchased outside the cost would be considerably less. Not only in the cost of the pattern itself is this true, but in the molding and machining. I know of one instance where a concern effected a saving of 15 per cent. in their pattern cost by having their patterns made by a concern who made a specialty of pattern making.

FORM 3.

### Purchasing Patterns

There are two methods of purchasing patterns, namely on contract and on an hourly plus material basis. If the former is to be employed the duties of the inspector are most important and the need of a man possessing a broad knowledge of pattern making, molding and machining from a practical standpoint is self evident. The hourly plus material system lends itself more readily to this work and when, as in any line or work, a reliable concern is employed, the results obtained are most satisfactory. It stands to reason that the company which specializes in one line of work can become most expert at it and can afford to install up-to-date machinery and keep abreast of the times. To those unable through volume of work to keep a pattern making department busy at all times, such a concern means a great saving.

The storing of patterns and the keeping of a record to locate them is very important. It avoids the making of a new pattern, and will in some instances through alterations avoid the necessity of making another pattern. The system used varies greatly with the nature of the business engaged in, but by careful study and consideration the patterns can be grouped so as to be easily and readily located.

Owing to the fire risk and more so to the vigilance of the insurance inspectors the pattern shop is generally kept clean and frequently swept. However a saving could be made in the majority of cases, if a closer watch was kept over all waste lumber. It should be a duty of the sweeper to sort and keep all nails, etc., found in the sweepings.

## A PORTABLE MOTION PICTURE MACHINE

F. C. P.

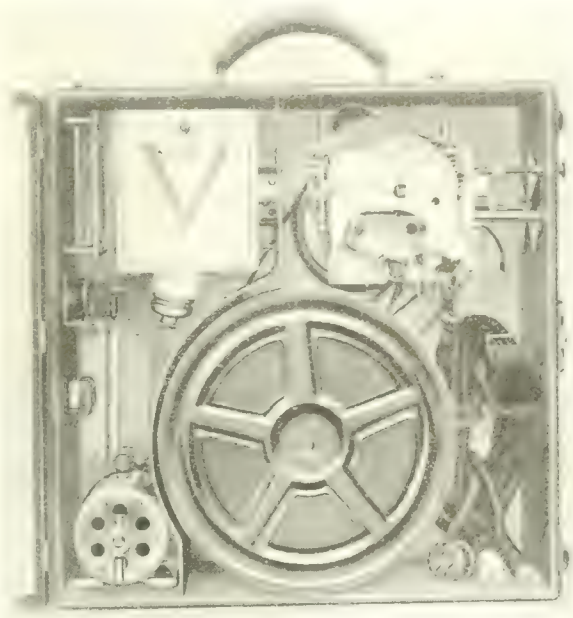
A recognized factor in sales work is the dealer's mental attitude, and the dealer must be genuinely enthusiastic about the goods, factory and entire organization. He must feel the advantages inherent in the product—then only is he prepared to sell successfully to the public.

A number of successful firms are using the motion picture machine in this manner and are securing splendid results. Notably among these are motor car manufacturers.

The motion picture projector is equipped with a film portraying, interestingly, the factory, the methods of manufacture and the product in actual service—and the dealer has at hand the most effective sales help which he could possibly have.

The salesmen handle the projector more conveniently than a suit case weighing as it does but 20 pounds, and is carried threaded, ready for instant use. Its operation is very simple, once connected with an electric light socket, the salesman need pay no further attention to its operation. He can concentrate entirely on his selling talk. There is tremendous selling force of a sales talk built around a motion picture of the factory, the methods and the product under actual service conditions.

This electric machine will project a 12-foot picture at any distance from 50 feet to 80 feet according to the focal length of lens. A 4-inch lens will give any size picture up to 12 feet in diameter, and any throw up to 50 feet



PORTABLE MOTION PICTURE MACHINE ADAPTED TO SALES PURPOSES.

Proportionately smaller size pictures at throws less than 50 feet.

A 6-inch lens will give any size picture up to 12 feet at any throw to 80 feet, and proportionately smaller-sized pictures at throws less than 80 feet. This does not prevent one from using the projector in a small room where there is but a 6 or 8-foot throw for 2 to 4-foot picture.

There is a small rheostat directly in back of the lamp house, which is connected up in series with the lamp, enabling one to vary the illumination to suit the size of picture, throw, density of the film or darkness of the room. The total current consumption does not exceed 500 watts, so that it can be attached to the ordinary light socket.

This projector is designed particularly for use for sales promotion work, publicity work and conventions, and a successful exhibition can be given before an audience of practically any size, as is frequently used for exhibitions before as many as 1,500 to 2,500 people. For "Safety First" meetings, where the lecturer goes from one factory to another, showing pictures under many and varied conditions, it takes care of all requirements.

## DEPARTMENTAL INTERDEPENDENCE IN FACTORIES

By M. M.

In the work of running a modern factory each department is more or less dependent on the preceding one as to the speed at which the work can be turned out, and this cannot be too well recognized by the responsible heads. If the drawing office sends good drawings to the smithy and pattern shops with the object of getting the best and easiest working from the smiths and moulders, and the pattern makers know—or will be told—the easiest way for dealing with any particular pattern in the foundry, then you can get your forgings and castings to favor the work of the machinists, and this department can again work to the advantage of the fitter and erectors, while generally the rate and volume of the output is accelerated, and all without any man working harder than usual. In cases where annealed malleable castings are made outside, it often occurs that much delay arises from causes connected with annealing, this raising the question as to whether it is not better to have one or more high temperature crucible furnaces and produce wrought iron castings directly fit for use as soon as cold, thus saving delay without appreciably increasing cost, as for most purposes this class of casting takes the place of the annealed castings. For all purposes of quick and full production it is assumed that the works are well equipped, and that no store's delays occurs, but each department must also quite clearly recognize that it is dependent on others to a large extent to enable it to secure a large and quick output of a continuous character.

SEMI-STEEL is considered to be a great heat and acid-resisting material since it is purer than grey cast iron. In recent tests for loss of weight under heat, grey iron lost 34 per cent. whilst semi-steel lost only 9 per cent. One direct practical advantage of this characteristic is evidenced by the demand for semi-steel bars for locomotive grates. Gears made from semi-steel frequently outwear steel gears, since the high graphitic carbon in the former acts as a lubricant. This is the greatest and most important point of difference between the two. In the case of semi-steel graphitic carbon exists in exceedingly small flakes and granules, whereas in grey cast iron the graphitic is usually present in the form of large flakes.—D. S.

THE types of aero engine in most common use are:—(1) Rotary, represented by Gnome, Le Rhone, Clerget. (2) Radial, represented by Salmson. (3) Vertical, represented by Beardmore, Green, Renault. (4) Vee, represented by Sunbeam, Wolseley, Rolls-Royce. (5) Arrow Head, represented by Sunbeam.

## LOCOMOTIVE REPAIRS

Maintenance of [illegible] ordinary industrial activity and unfavorable [illegible] strain that is placed upon the overworked and heavily taxed locomotives, with [illegible] hauling and repair, makes the question [illegible] vital of railroad problems.

[illegible] the past winter, and its further signi[illegible] of the Canadian Railway Club at Montreal, when a very comprehensive paper was presented to the meeting by E. R. Battley, master mechanic of the Grand Trunk Railway; a reprint of this paper appeared in the March 28th issue of CANADIAN MACHINERY. While the article in its entirety dealt very thoroughly with the importance of proper facilities and effectual methods of handling the work, through suitable equipment and systematic organization, it also formed a basis of an interesting and instructive discussion, in which many of the members participated, proving the extreme value of the paper as an educational feature, particularly under existing abnormal conditions.

In opening the discussion, W. H. Winterrowd emphasized the difficulty the C. P. R. and other roads had experienced, especially during the past winter, in obtaining anything like a sufficient supply of skilled labor. One of the fundamental problems of present-day railroad shop maintenance—and the same may be said to apply to all other industries—is the making of mechanics out of the class of men that are offering themselves for employment. This might be summed up in the words of Mr. Winterrowd:

> "It used to be possible for an engine-house foreman to instruct his men to perform certain work. This cannot be done to-day. Conditions are such that the foreman is compelled to direct almost every movement of unskilled labor."

With reference to machinery and other shop equipment, it was pointed out that maximum efficiency was only attainable by adopting systematic handling of the material. Proper routing of the work was necessary to avoid overlapping. Speaking on the importance of this, and the economic feature of handling work rapidly, Mr. Winterrowd said:

> "At the Angus shops of the C. P. R. the electric storage battery trucks have been a very important factor, and material is moved in and out of the stores and through the various shops in a minimum time and with minimum labor."

What mileage a locomotive should cover before being sent to the shop for repairs has always been a debatable question, and it is doubtful if a satisfactory basis could be arrived at under present conditions. In commenting on this, Mr. T. C. Hudson said:

> "It is difficult to arrive at just what mileage a locomotive should make between shoppings, as the conditions under which they operate vary so much. The size of the wheels should be considered and the conditions known as to grades, curvatures, etc. A small wheeled engine in heavy freight service has a tendency to wear tires down quickly, and sometimes it is impossible to get more than 35,000 or 40,000 miles between shoppings. On the other hand, it has been found possible to get more than double this mileage from a large wheeled engine in through freight or passenger service."

Apart from the general deterioration, due to ordinary wear and tear, other factors are involved in the running of a locomotive that have considerable bearing on the service period between overhaulage. Not the least of these is the unknown—or rather variable—quantity of the human element. No two engineers will be of one mind regarding the operating details of locomotive running. Very often the question of lubrication, properly or improperly applied, may mean a difference of several hundred miles, or days as the case may be, in the service period of the engine. Difference of opinion between the operating engineer and the locomotive foreman as to what repairs are actually necessary after a run is sometimes a question for argument, and frequently an engine may be placed again on the road owing to the lack of available material with which to make the needed repairs; such conditions may materially affect the serviceable life of the locomotive. In this connection Mr. Winterrowd said:

> "Another point regarding the maintenance of power on the road and its repairs at the shop is the proper utilization of material and having the same on hand when required, and also the utilization and reclamation of materials that can be put to use in place of new material."

The making and replacement of piston rings received some attention, following a question regarding the machining of the ring bore. In answer to this, Mr. Winterrowd said:

> "The amount of finish you put on the ring depends upon the way the ring is made. If you have a fine casting it may not be necessary to do it at all. Our usual practice is simply to rough away a small amount of the rough spots."

Frequency of cylinder repairs was claimed to be the result of inexperience or thoughtlessness on the part of the operating engineer or his fireman, who in many instances overlooked the consequences of carrying too much water in the boiler. As stated by Mr. W. Spence:

> "I would like to say that amongst engineers some of us are under the impression that the locomotive cannot be properly handled with a full boiler of water. My experience has been to run with as low water as you can consistent with safety, but always have enough, so that if the inspirators should fail you will have sufficient time to dump the fire. In running with a full boiler of water we do not get good results. It destroys the lubrication, also the piston rings, and the engine will not give good mileage. You can destroy the rings in a hundred miles if you are not careful of the water."

J. W. Buckland, in speaking on the advantages of preparedness, intimated that it was generally found that brake gear and spring gear would "break in the spring-time," and thought it would be advisable to have materials ready to ship for prompt replacement. He said:

> "We could keep more locomotives running if we had the material ready to ship out to the point required, and not wait until the locomotive foreman discovers that some casting has been broken and has to order it through the stores, taking ten days or two weeks to get it."

Commenting on this subject of prompt repairs, E. J. McVeigh said:

> "One of the best locomotive foreman I ever knew told me that he considered the only plan on which to run a roundhouse was to run it the same as a fire station—always be ready for the unexpected, and expect it to happen."

Mr. McVeigh also dwelt briefly on the need of closer co-ordination of officials and department heads. He thought this feature was a weak link in the existing organization, as many were reluctant to acknowledge or recognize the weakness. He said:

> "The trouble is that when the mechanical department change a standard they throw out something that has been in use for years and call it obsolete, but they say nothing to the supply department until they want the article, and we then discover that they have been waiting for it for the past two weeks. If we could have closer co-operation there is no question but that the railways would receive considerable benefit."

In reply to a query by G. E. Smart (chairman) regarding the adoption of standard accessories, Mr. Winterrowd said:

> "On the Canadian Pacific Railroad when a locomotive is designed or redesigned we always keep in mind the parts already in existence on other engines. The interchangeability of parts is a very important matter, and on this road there are always a very large number of locomotives on which parts are interchangeable."

In this connection Mr. T. C. Hudson stated:

> "We have found that it is good practice and pays to standardize as far as possible the parts that enter into the maintenance of locomotives, such as grates, injectors, crossheads, etc. This is a considerable advantage, especially to the locomotive foreman, as he requires all our sympathy and help in this respect, so that he may

be able to make repairs promptly and keep the wheels turning, especially at this time when it is almost impossible to get new equipment. The stores, no doubt, do all that is possible, but in some cases material can not be secured owing to war conditions; and on this account we have had to make material from the scrap pile and use our ingenuity in making it into articles, which, before the war period, would not have been considered good practice."

The possibility of discrimination in favor of particular equipment, or adopted an elastic standard to cover the various makes, was advanced by Jas. Powell, secretary. He thought it well to include as many standard parts as possible, but said:—

"In the case of specialties, such as injectors and mountings, if you decide to adopt one make as standard another manufacturer comes along and points out the particular advantages of the appliance he has for sale, as against the one you are then using, and his appliance may be used. The result is that you get away from standards."

The consensus of opinion appears to be that it is essential that every facility be provided to enable the locomotive foreman to make necessary repairs with the least possible delay. The position of this official is not an envious one and therefore every encouragement should be given him in the discharge of his duties. Speaking along these lines, E. S. McMillan said:

"I never ran across the man yet who pined for the job. We have come across little boys who wanted to be motormen or locomotive firemen, but I have not yet met the man who was anxious to take on the job of locomotive foreman."

The keys to the situation are apparently sufficient organization, close co-ordination of men and departments, and the development of a higher standard of skilled workmen. Apart from the general all-round acquirement of the foreman in charge, the capabilities of each individual workman are factors that go a long way in making or marring the success of this branch of the service. Conscientious training of the men is an essential necessity. The practice of the C. P. R. in this connection was stated by Mr. Winterrowd in these words:

"We endeavor to specialize in assigning the work which these men have to do, which means that the closest supervision is necessary to obtain good results. The question of careful supervision and training of the men is a vital one."

## FIRE PREVENTION AND DIRT IN WORKSHOPS

By M. M.

Although the majority of workers in a workshop think that it is a place where all dirt can be deposited it is really very necessary that the workshop should be kept as clean as a housewife keeps the kitchen at home, and if this was done there would be a great saving of wastage of material, labor and time which is caused by fires. The greatest cause of fires is disorder, the neglect to clear away the refuse of manufacture, shavings, and sawdust for example. In one workshop a bottle had been found containing petroleum under some shavings, and inquiry elicited the information that it belonged to a man named "Old Joe" who had left three months previously. It should be remembered that many kinds of waste are subject to spontaneous combustion, or in other words, to the generation of heat through oxidization. Experiments made with some dirty cotton "wipes" showed that the temperature had gone up in six hours from 70 deg. to 440 deg Fahr.

Many accidents happen from the fact that cleaners do not sweep under the mat. It is also quite common for them to leave a ring of dirt round the gas stove. Then, where men are allowed to get their dinner in the factory—a most objectionable practice—the greasy sandwich papers are allowed to lie about and often generate heat. It is essential that workmen should not only be expected, but allowed, to clear up after work. It is also a valuable example.

Out of 3,609 fires in the city of London in 1914 no less than 1,415 have been scheduled by the fire brigade authorities as due to carelessness and probably the same proportion of fires all over the world is due to the same cause. In one case there had been paper chains on the gas lights, in another a man snatched a light from a girl in a celluloid factory, and then struck a match to find it amongst the celluloid chippings. Several lives were lost in the fire which followed. A bad fire was caused in one factory owing to the hands not having a place in which to put their coats and hats. One of the men had left a lighted pipe in his coat which he hung up under the staircase. Again, it is common to find that there is nothing provided with which to put out a fire—no extinguisher or water buckets or hydrants or hose. Again, the amateur factory brigade often proves inefficient when a real emergency arises, and in one case it was found necessary to get a crowbar to get at the hydrant, and when at last this particular brigade had got the trap open, they found it was a drain and not a hydrant.

In the choosing of a watchman care should be exercised, and a watchman should most certainly not be selected because he was the oldest man in the works. That is the very reason why he shouldn't be chosen. Tell-tale clocks should certainly be used, and in a place where dangerous things are made one watchman had been allowed to walk round and pick up a great deal of grit on the rubber shoes provided. However, this particular watchman was wary and did not go into this part of the works until a pair of unused rubber shoes had been brought. With the tremendous increase in factory work it is surprising how few precautions against fire are taken. Employers do not seem to realiez the responsibility that rests on the provision of suitable fire-fighting appliances. Again, coal is liable to spontaneous combustion, and to avoid this it should not be stacked more than 10 feet high. Coal of course differed in readiness to fire. Iron pipes should be inserted in the stacks at a distance of 50 feet, and when a thermometer lowered down these pipes showed 110 deg. it is necessary to look into the matter twice a week. If the heat does not go down trenches should be made a foot deep. If water is used there should be plenty of it. Iron trimmings are also subject to heating. They begin to oxidize, and wood or other inflammable material mixed with them soon causes a fire. Sometimes the wood will get full of grease or petrol and on one occasion a loss of $250,000 was caused by the petrol being fired by a greasy rag.

## MONAZITE FOR GAS MANTLES

By M. M.

The mineral survey now being conducted in Ceylon in co-operation with the Imperial Institute has led to the discovery of beach deposits of monazite sand which will usefully supplement the commercial supplies of thoria required for the manufacture of incandescent gas mantles. Samples of the sand have been investigated by the Imperial Institute and the results are so promising that the Government of Ceylon has arranged to work the deposits. Suitable British concentrating machinery has been selected by the Institute for the purpose, after experimental trials, and will shortly be shipped to the colony.

This is the last chapter in the story of the long struggle to rescue the gas mantle industry from German domination. Formerly the monazite sands in Brazil were the only commercial source of supply of thoria, and these were controlled by the German Thorium Syndicate. The Brazilian monopoly was broken by the discovery of extensive deposits in the native state of Travancore in India, so rich that samples examined by the Imperial Institute were found to contain nearly twice as much thoria as the Brazilian deposit.

The German syndicate, however, obtained control of the company formed to work the Indian deposits and continued to exercise a dominating influence in the industry till the outbreak of war. Since then the company has been reconstructed, and given a British character, and it is understood that another portion of the deposits in Travancore has been taken up and will be worked by a second British company. It is of interest to note that the work of the Mineral Survey has shown that Ceylon can furnish several thoria minerals besides monazite, and amongst these is thorianite, the richest known source of thoria. This new mineral when it first came on the market was sold in the British Isles at as high a rate as £1,600 per ton, but the deposits have proved to be fairly limited.

## INDUSTRIAL GYMNASIUMS

By F. R. A.

[illegible] gymnasium in Cleveland, Ohio, U.S.A., provided by a manufacturing company, which may be emulated by [illegible]

Vigorous physical exercise daily, under the direction of a trained instructor, conserves the health of the employees and builds up the physical endurance of the men to a point which later on will enable each man to assume added responsibility, if necessary.

It is of interest to note that the plan applies to the executive officers, superintendents, managers, heads of departments and others on whom rests the responsibility for the solution of important manufacturing and selling problems. Under the provisions of the new plan which has been tried out thoroughly, the men holding responsible positions are urged to spend an hour each morning [illegible] gymnasium which has been completely equipped in the basement of the administration building. The men enrolled in the different classes are paid by the company for the time they spend in the gymnasium and no business appointment or other important task is permitted to interfere with this schedule. The men are compelled under the penalty of a heavy fine to report at the gymnasium at a specified time and are not permitted to leave until the class is dismissed.

While many other large industrial firms have erected pretentious gymnasiums in times of peace for the optional use of their employees outside of regular business hours, this is the first concern to start a movement of this kind to improve the health of its employees and pay them for their time to make them more efficient.

It is pointed out by the officials of this industrial plant that members of President Wilson's Cabinet have been taking regular exercise daily under the personal direction of Walter Camp and their program is along the same lines as the plan in effect at Cleveland. The Government realizes the great benefit to be derived from regular exercise and is recommending that all manufacturing and industrial plants set aside fifteen minutes a day to be devoted to breathing exercises and light calisthenics. The American soldiers abroad spend several hours a day in athletic games. Troops landing in France are immediately marched to an athletic field where they participate in interregimental games. This exercise limbers up their muscles after the long journey on the transports.

The results of the training, so far, have been gratifying to both the company and the men. The plan may, later be extended to include all of the five thousand or more bookkeepers, clerks, accountants, salesmen, stenographers, skilled and unskilled workmen in the plant.

An experienced athletic coach and director, who is a graduate of the Chicago Training School and prominent in Y. M. C. A. circles all over the country, conducts the course of instruction outlined for the busy factory workers. It consists of passing the medicine ball, setting-up exercises, stall bar work, hand ball, wrestling, club swinging, bag punching and many other forms of calisthenics. Following a strenuous workout in the gym. the men jump under a battery of shower baths. During the first few weeks there are always many sore and aching muscles, lame backs and stiff joints that require attention. All the men are required to undergo a rigid examination by the medical examiner and the doctor makes out a comprehensive report of his findings and this is filed in the superintendent's office. The examination is repeated regularly every month and compared with the original report. The records are carefully kept and are as accurate as it is possible to make them.

In case a man is found to be nervous, underweight and suffering with some minor trouble, he is given medical attention and advised by the physican and physical director as to the proper course to pursue to improve his condition. In many cases a change of diet and the consumption of plainer foods that give greater nourishment have helped materially to remedy the ailments. The vice-president of the company, who fathered the adoption of the preparedness idea, is highly pleased with the results which have been obtained and declares that it has set up a new social equality between the officers of the company and its department managers.

This gymnasium is considered to be one of the most democratic institutions in the world, as it is a place where men meet on an equal basis and get to know each other more intimately, as they are dressed alike, do the same stunts and forget their business cares, and it gives them new enthusiasm and better spirit.

One of the superintendents, who is 36 years old and weighs 216 pounds, joined the class, experiencing for a time great difficulty, as he had never taken up any gymnasium work before. His muscles were soft and flabby and his weight made it almost impossible for him to perform many of the gyrations. It was necessary for him to start in very slowly, but after attending class regularly for a period of ten weeks he is now able to take the regular work assigned to any of the other members. In this time he has reduced his weight 7½ pounds and his waist measurement 1½ inches, while his chest expansion has increased ½ inches; right arm 1 inch; left arm ½ inch; left and right leg each 2 inches. His health was never better and he is now losing from ¾ to 1 pound a day.

It is declared that while the fat men lose weight under this strenuous daily exercise, the thin and underweight men gain, as a foreman 47 years old, who tipped the scales at 122 pounds when he enrolled in the class, is now 5½ pounds heavier and many of his other measurements have increased from 1 to 3 inches and he says that he is getting stronger every day.

CLASS AT WORK IN GYMNASIUM OF LARGE INDUSTRIAL PLANT.

Gymnasium work of this nature cures minor ailments. Three other members of the class were reticent about taking up the work as one was recovering from a prolonged illness, while the other two suffered with indigestion and stomach trouble. The first gained 13 pounds in weight, the second 7½ pounds, and the third 2 pounds, and all say that their health is much improved. Some men who complained of having too large a waist measurement and protruding stomachs have been able to reduce them as much as 2¾ inches and expect to take off a few more inches within the next few weeks. A table has been compiled with data of a few members of class number one, the ages of these men ranging from 32 to 48 years and all have been in the employment of the company from ten to thirty years. This table bears out the statement that all who have taken advantage of this gymnasium have been greatly benefited by the course of training.

# Notes on the Design and Testing of Air Lift Pumps--I.

By A. W. Purchas

*The air-lift pump has become one of the most economical methods of raising water, the simplicity of construction and the almost entire absence of moving parts giving reliability in operation and avoiding the necessity for skilled supervision. The design of these pumps being subject to more or less development the subject matter of the following article is of more than passing interest.*

THE subject of air-lift pumping has not received the attention it deserves from engineers, and has fallen into disrepute with many. There are several good reasons for this, among which may be mentioned the lack of a satisfactory theory, the low efficiency of most installations, and the lack of complete and accurate reports of tests, so that the causes of the low efficiency are obscured.

An attempt is made in this paper to rectify the first, to show how the second can be improved, and to point out in what respects many reports of tests are lacking in information essential to a thorough analysis for checking theoretical formulae and deductions.

An account is given of several series of tests, with a description of the methods and the equipment. The theory of the pump is then reviewed, and a novel method of approaching the subject is given, from which it should be possible to evolve rational formulae for designing.

### Equipment and Methods for Testing

General.—The wells on which these tests were made form part of a water supply system, of which an account was presented to the Institution of Civil Engineers some time ago. Series A of tests was given at that time, but further investigation showed that the author had wrongly calculated the actual volume of air used, and the average velocities of the rising mixtures in the eduction-pipe. By their kind permission, it is possible to reproduce these test-figures with the errors corrected, and other valuable deductions added.

On pulling the eduction-pipes from the wells, after they had been in operation for some length of time, the interior surfaces were found to be heavily encrusted with nodules of rust, some ⅜-inch high, of such rugged outline as to leave no trace of smooth contour on the surface of the pipe. The tests of Series A are of one eduction-pipe when newly installed, and the tests of series B are of the same pipe when encrusted as described above. A comparison of these two series shows some very interesting points. Fig. 9. The eduction-pipe used in the tests of series C was badly encrusted, but that of series D was clean.

Air-Injection Foot-Pieces.—The foot-pieces used in the various tests are shown:—

For Series A in Fig. 1
For Series B in Fig. 1A
For Series C in Fig. 2 and 2A
For Series D in Fig. 3

The merits and faults of these are discussed later under the theory of the pump (page 13).

*Read before the Institute of Electrical Engineers, November, 1917.

### Lift

In series A and B this was measured by lowering a float on the end of a steel tape line between the eduction-pipe and the well-casing. The float was a piece of wood ¼ inch by 1 inch in section, and 6 feet long, weighted to float upright with about 5 feet submerged. This method, however, is not recommended, as the float will sometimes become wedged between the pipe-couplings.

In series C and D the lift was measured with the device shown in Fig. 4. This consists of a piece of heavy brass-pipe, inside which a small copper-float is free to slide at the least impulse. The whole is suspended by a duplex rubber-covered cable, graduated in feet, one wire of which is connected to the case, and the other terminating in a lump of solder on the lower side of the insulator, which forms the top of the case. At the top of the well an electric bell and batteries completed the installation. The case was lowered into the well, and its reaching the water surface was indicated by the bell at the ground surface ringing. By this means it is possible to measure the depth to the water surface within an inch. It is absolutely impossible to estimate correctly the lift from the gauge-pressure of the air at the well-head, and this should never be attempted. Some injection foot-pieces put from 5 to 10 lb. per square inch extra pressure on the air, and there sometimes is a loss of 5 lb. pressure due to friction in the air-pipe. A combination of these losses might make an error of 30 feet in the estimated lift. To estimate the lift from the air-pressure required to start the well flowing is equally impossible since, once the well is started, the lift nearly always increases. Reference to tests 1, 2 and 3 of series D, among others, shows that under certain conditions the air-pressure at the well-head may be less than that equivalent to the submersion head of the foot-piece. This may be accounted for by noting that a column 600 feet high of air under 135 lb. per square inch pressure will exert an additional pressure on the base of a column of 3.25 lb. per square inch, due to its weight.

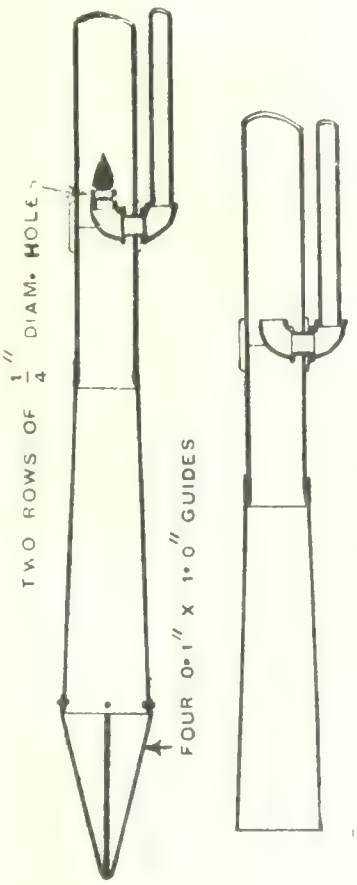


FIG. 1. SERIES A.

FIG. 1a. SERIES B.

An alternative method of measuring the lift is recorded by Mr. Kenneth Allen in a paper read before the Engineers' Club, of Baltimore (in 1908, on the wells at Atlantic City, U.S.A.

### Air-Compressor and Measurements of Air Used

The air-compressor is a two-stage, with both air and steam cylinders compounded. The sizes of the more important parts are as follows:

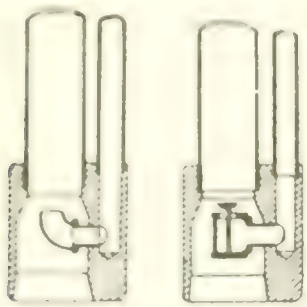
| | |
|---|---|
| Diameter of the air-cylinder | [illegible] |
| Diameter of the steam-cylinder | [illegible] |
| Stroke of the pistons | [illegible] |

The air is drawn through a combined forecooler and filter outside and on the shady side of the building, and passes through an intercooler between the two air-cylinders. The cooling water is circulated by a double-acting piston pump of 5½ inches bore, and 5 inches stroke, driven direct from the crank-shaft of the compressor. The suction valves of the low-pressure cylinder are semi-rotary, and are mechanically opened and closed by an eccentric on the main crank-shaft. All other air-valves are automatic, spring loaded and air-cushioned.

Many tests, which would otherwise be of the greatest value to the designer, are rendered of only doubtful value because the volume of air used was not carefully measured; hence the average velocities of the rising mixture can only be approximated. These velocities are the most important items affecting the efficiency of the pump, and those on which more than any other accurate data are required at the present time.

It is found in checking the published figures from too many tests that the volume of air used was calculated from the known displacement of the low-pres-

— that the temperature at the beginning of the air at the intake.



The true volumetric efficiency of a compressor based on the ratio of air drawn in at atmospheric pressure and temperature to the displacement of the low-pressure piston will vary:

The above figures are taken at random from various sources, and it is impossible to state average values.

Returning to the tests here recorded, prior to each series the air-valves of the compressor were examined, and their seats put into good condition. On 25th and 26th April, 1914, tests were made of the volumetric efficiency of the compressor, and again on 7th and 8th May, at the end of each test of the air-lift pump. The discharge from the compressor was measured by means of an orifice, the form of which and the method of connexion to the air-receiver are shown in Fig. 5. This meter is a duplicate of that used by Professor R. J. Durley, of McGill University, Montreal, to determine the coefficients of the discharge or air through certain forms of orifice. An account of his work is to be found in the Transactions of the American Society of Mechanical Engineers, vol. 27.

The formula given in the above paper for calculating the flow through the orifice, is:

$$Q = 0.6299 \ Cd^2\sqrt{\frac{i}{T}},$$

Q is the weight of air passing through the orifice in pounds per second.

C is the coefficient determined by experiment.

$d$ is the diameter of the orifice in inches.

$i$ is the pressure inside the meter-box

T is the absolute temperature F. inside the meter-box.

This formula only applies to sea level,

above, the following formula was used to compute the discharge:

$$Q = 0.1632 \ Cd^2\sqrt{\frac{i}{T}} P^a$$

$P^a$ is the absolute pressure in pounds per square inch of the air inside the meter-box. This equals the barometric pressure, plus 0.036 $i$.

For testing air-lift pumps, it is probably more convenient to install a meter in the air line between the compressor and the well. This is more expensive to install, but the volumetric efficiency of a compressor is a very variable quantity, which cannot otherwise be measured during the tests of the well-pump. Such a meter is shown in Fig. 6. The principle is identical with the foregoing, and the same coefficients of discharge

FIG. 3. SERIES D.

may be presumed to apply, if the velocity of approach and the head be maintained within the limits tested by Professor Durley. In this meter the discharge will be found by means of the formula:

$$Q = 0.1632 \ Cd^2\sqrt{\frac{i}{T}}p,$$

in which—

$i$ is the difference of pressure on the two sides of the orifice, measured in inches of water.

$p$ is the average of the absolute pressures of the air on the two sides of the orifice.

From the foregoing formulae, the volume of air is found by the formula:

$$W = \frac{p}{53.17 \ t},$$

in which—

W is the weight in pounds per cubic foot.

$p$ is the absolute pressure in pounds per square foot.

$t$ is the absolute temperature F.

A third and similar method of measuring the volume of air is possible through the research of Professor William Watson and Mr. Herbert Schofield, who determined the coefficient of orifice placed in the suction-pipe of a compressor.

### Quantity of Water Raised

The discharge-pipes of the wells at Oilfields rise about twenty feet above the ground, and discharge over the rims of small tanks, against curved hoods which deflect the water downwards. The pipes are bent to gradual curves, and the last few feet are inclined about 70 degrees to the vertical. Permanent derricks of a light California oil-well pattern are built over the wells, and were the discharge-tanks erected vertically over the wells, they would have to be removed each time the eduction-pipes were pulled. From these small tanks the water gravitates through 6-inch mains, laid along an overhead platform,

to two 84,000 gallon corrugated galvanized iron tanks and one wooden tank of like capacity. The iron tanks average 32 feet 9 inches in diameter, and 13 feet 4 inches in depth. The circumference of each ring of these tanks was carefully measured and checked, also the depth of the corrugations and the thickness of the plates. These measurements were taken when the tanks were full to the level at which the measurements were being taken, and from these figures a table of capacities was prepared for each eighth of an inch of depth.

Prior to each test, the well was pumped for sufficient time to allow all conditions to become constant, and the water meanwhile delivered into one tank. At the commencement of the test the water was diverted into another tank and switched back into the first again at the end of the test. All outlets from this measuring tank were closed and under observation at all times during the test.

Such facilities for measuring the quantity of water are rarely available, but there are several alternatives, such as weirs or Venturi tubes, which give equally accurate results. Many tests record only the combined performance of two or more wells; this is unfortunate both from the owner's point of view, and from that of engineers, as the information is too general; the extra cost of individual meters for each would undoubtedly be justified by showing some chance of improvement in the efficiency of one or more of the wells.

One writer who has contributed the results of some very instructive tests, measured the quantity of water pumped in a reservoir, the size of which unfortunately would only permit of runs of ten minutes' duration. It is the author's opinion that no test of an air-lift pump should be of less than one hour's duration, and that it is better to run this length of time and measure the water with some form of calibrated meter, than to run shorter tests and measure the water in any other way.

### Indicated Horse-Power of Compressor-Air Cylinders

For this purpose an external spring Tabor indicator was used. This instrument had seen but little use, and was in perfect condition throughout. Great care was exercised throughout the tests to obtain true representations of what was taking place inside the cylinders. The revolutions of the compressor were recorded by an Ashcroft counter, and were controlled by a steam throttle-governor, which was operated by the variation of both the speed of the engine and the pressure of the air in the receiver.

### Nature of the Discharge from the Wells

These observations were taken by two observers for three periods of five minutes each during each test. Where the discharge was 50 per cent. or more of the total cycle, the intervals were remarkably constant. The values here given are averages of times observed with an ordinary watch:

Series A.—These observations were recorded in the paper presented to the Institution of Civil Engineers, and are therefore not repeated.

Series B

Test 1. Periods of discharge of thirty-five seconds' duration at intervals of one minute and twelve seconds.

Test 2.—Periods of discharge of forty-three seconds' duration, followed by a pause of five seconds, then a discharge of perhaps ten gallons, followed by a pause of thirty-three seconds before the cycle recommenced.

Test 3. A steady flow of emulsion ending in two short and violent ejections, the whole lasting thirty-three seconds. After a pause of five seconds, there would be a discharge of ten to twenty gallons, followed by a pause of twenty-eight seconds before the cycle recommenced.

Test 4. Periods of discharge of thirty-three seconds' duration at intervals of twenty-three seconds. During the interval there would be one fairly strong spurt lasting one second.

Test 5. Periods of discharge of one second at half-second intervals.

Tests 6, 7 and 8. Discharge similar to that of Test 5, but at higher velocities.

In all cases the discharge consisted of an emulsion of air and water, and not of alternate volumes of air and water, as Dr. Pohle claimed for his system.

Series C

Test 1. Periods of discharge of forty-two seconds' duration at intervals of two minutes and seven seconds.

Test 2. Periods of discharge of thirty-six seconds' duration at intervals of fifty seconds.

Test 3. Periods of discharge of forty-one seconds' duration at intervals of twenty-six seconds.

Test 4. Periods of discharge of two to four seconds' duration at intervals of two to five seconds. Very irregular.

Test 5. Very similar to that of Test 4.

Test 6. Similar to Tests 4 and 5, but the intervals did not exceed half a second.

Tests 7 and 8. Very similar to Test 6.

Series D

Test 1. Periods of discharge of forty seconds' duration at intervals of fifty-two seconds. During these intervals, however, there were five discharges of one to ten gallons each.

Test 2. Periods of discharge of five seconds' duration at intervals of five seconds.

Test 3. Periods of discharge from five to ten seconds' duration at intervals of five seconds.

Test 4. Periods of discharge of short duration, one beginning before the previous one had quite subsided. The velocity of discharge did not appear to be as high as in Tests 2 and 3.

Test 5. Similar in nature to that during Test 4, but at higher velocity.

Tests 6, 7 and 8. Practically continuous discharge of emulsion of small air bubbles and water.

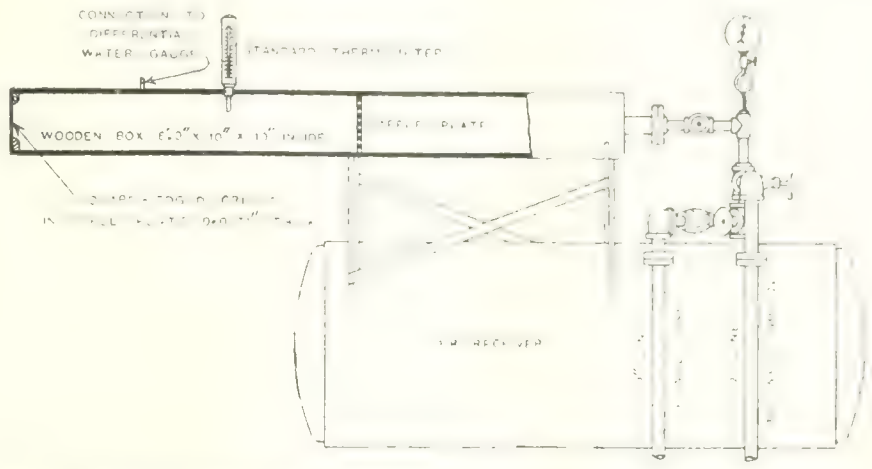

FIG. 5 ORIFICE METHOD FOR MEASURING THE VOLUMETRIC EFFICIENCY OF A LOCOMOTIVE AIR COMPRESSOR.

### Method of Recording Observations

The comparison and analysis of published tests will be greatly simplified, if some standard form can be adopted. Most of the published tests lack certain important items, and other information, such as the submersion, is given in different ways, so that their analysis requires considerable work.

The author has adopted what he believes to be the most convenient form, and one which includes all details necessary to examine the behavior of the pump itself. The observations might, of course, be extended to include every part of the plant down to the fuel consumption, but such details can be foretold with fair accuracy by the manufacturers of the compressor. Since efficiencies of 80 per cent. seem possible with the air-lift pump in the near future it would not seem inopportune for some authoritative body to outline a method of making and recording tests of the air-lift pump, and its reverse the entanglement type of hydraulic air-compressor.

Probable Accuracy of the Tests at Oilfields

Water Pumped.—The [illegible] equivalent to:

Horse-power of the Air Compressor.—The probable maximum error would be [illegible] of series D.

Volumetric Efficiency of Compressor.—The probable error in measuring the volume of air flowing through the orifice during the tests of series D is not more than 2 per cent., as the pressures and temperatures were all recorded within this margin. The values assumed for the tests of series A, B, and C, were based on the experiments made in April and May, 1914, taking into consideration the following :

(1) The speed of the compressor.

(2) The known condition of the air-valves and guides.

(3) The volumetric efficiency shown on the indicator cards.

(4) The temperature of the air in the compressor suction pipe.

(5) The known condition of the scale in the cooling jackets, and the quantity of cooling water supplied. The cooling water was supplied by a piston pump driven direct from the compressor crank-shaft, in all cases.

It is difficult, therefore, to form a definite opinion of the probable accuracy of these latter values.

Indicated Horse-Power.—The maximum difference between the highest and the lowest "mean effective pressure" recorded during any one test, for the same end of a cylinder was 1.3 per cent. for the low-pressure cylinder, and 1.8 per cent. for the high-pressure. Considering the attention paid to details in the use of the indicator and the low speed of the compressor, the probable accuracy of the values given for the indicated horse-power is within 1 per cent.

### Theory of the Air-Lift Pump

This subject is here treated in the following sequence:

(1) Design of air-injection foot-pieces.

(2) Nature of the rate of change of velocity of the mixture to the eduction-pipe.

(3) Operation of the pump as a whole.

(4) Submersion of the injection foot-piece.

Foot-Pieces.—The design of the foot-piece does not play such an important part in the ultimate efficiency of the pump, provided:

(1) That the fundamental laws of the losses in transmission of air and water are carefully kept in mind, when designing; and

(2) That the air is injected into the water in the form of small bubbles.

Any attempt to use the injector principle is pure waste of time, and generally leads to throttled air and water passages, and a back pressure on the air of two to five pounds per square inch, which represents so much wasted energy, for which no corresponding gain can be shown elsewhere. This throttling effect is very marked in the tests by Messrs. Brown and Behr, which were made with an inch diameter air-line terminating in a ⅝-inch diameter nozzle. Some of the tests by Messrs. Davis and Weidner show the same fault.

Fig. 1 shows the foot-piece used by the author in the tests of series A. Its obvious fault is the contracted water-passage, and its only excuse is its cheapness. The real reason that this was abandoned was the choking of the bottom of the air-pipe with rust and scale, so that eventually it caused an additional air-pressure of 30 lb. per square inch. Alternate exposure to warm air and water will corrode steel at an extraordinary fast rate. Before putting the eduction-pipe back into the well, after discovering this trouble, the "eddy cone" was removed, and series B of tests was made with the foot-piece shown in Fig. 1A. The foot-piece shown in Fig. 2 was originally used in Well No. 1, the aim being to inject the air in the form of small bubbles. This type suffered from the same faults as the previous ones. Series C of tests was made with the type shown in Fig. 2A.

When Well 2 was last re-tubed, it seemed probable that the eduction-pipe then inserted would be the largest ever required, and therefore full advantage was taken of previous experience and first cost was not so important. Fig. 3 shows the design of the resulting foot-piece, and this is the type used in series D of tests. The following points were aimed at in the design:

(1) To avoid loss of air-pressure in transmission from the well-head to the foot-piece, and keep the air-pipe outside the eduction-pipe without resorting to the use of the annular space around the outside of the eduction-pipe. An air-pipe run inside the eduction causes additional frictional losses in the rising mixture, with no corresponding gain elsewhere.

(2) To provide a pocket to catch such scale and rust as may form in the air-pipe, and thence fall into the foot-piece.

(3) To introduce the air into the water in the form of small bubbles, as it has been claimed that the velocity of slip of an air-bubble through water varies as the square root of its volume. Since designing this foot-piece the author has found that Mr. Joseph P. Frizell, member American Society of Civil Engineers, outlined the same type of foot-piece in 1880, and in "Engineering News" of 8th June, 1893, referring to the reverse process of compressing air by entanglement with falling water, wrote: "This method was suggested by observing the very moderate velocity with which bubbles of air rise in still water, the velocity varying with the size of the bubble, from nine inches per second or thereabouts for minute bubbles such as result from a slight agitation of the water, to as many feet per second in the case of great masses of air."

Mr. Kenneth Allen, describing the equipment and tests of the wells under his charge at Atlantic City, U.S.A., in a paper read before the Engineers' Club of Baltimore in 1908, also from his experience supports the same.

Mr. Edmund M. Ivens, on page 143 of his book, "Pumping by Compressed Air," writes: "The small openings mentioned divide the air bulk into small streams and thoroughly aerate the column. Considerable gain in economy over other systems is realized thereby, as may be seen by comparison of the curves and tables."

(4) To provide orifices for the air that would not corrode and choke up, as did those drilled in steel and used in the foot-piece shown in Fig. 1

(5) To so proportion the water passages that there should be no sudden change in the velocity of the rising column. The water-passage at the bottom is 6 inches in diameter. From this point upwards the passage gradually contracts, and the water therefore is gradually accelerated until it reaches the bronze taper-nipple. As the water rises through this, it is assumed that the air is uniformly admitted through the 120 ¼-inch holes, and that the velocity of the mixture is constant. Beyond this nipple the velocity of the mixture gradually increases until the size of the eduction-pipe is increased.

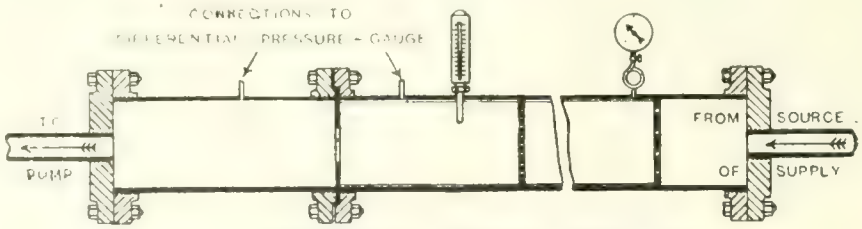

FIG. 6. HIGH-PRESSURE AIRMETER ORIFICE TYPE.

(6) To provide some form of guide on the lower end of the foot-piece as shown in Fig. 1, to prevent its catching in the joints of the well casing when being lowered into the well.

There is no necessity for the foot-piece to be as long as that shown, unless it is so built as to form an auxiliary air-reservoir at this point; a feature which has some advantages. It is equally possible to combine all the above points with the exception of No. 1 in a

foot-piece to be used on an air-line inserted inside the eduction-pipe, and this latter construction is sometimes necessary if the well casing be small.

**Velocity of the Rising Mixture**

The air in the eduction-pipe expands as it rises, due to the diminished head of liquid above it, and it may safely be assumed that it does so isothermally on account of the large volume of water by which it is surrounded. In the case of a single bubble of air rising through water, the pressure on the bubble will vary directly as the head of water above it. In an air-lift pump in operation the air-bubbles are rising through a mixture of variable density, since the ratio by volume of air to water per foot length of eduction-pipe increases as the outlet is approached. Under these conditions the pressure in the eduction-pipe will vary as the ordinate to a hyperbolic curve, and the volume of each bubble as the ordinate to a straight line.

To find the volume of air passing any point in the eduction-pipe per unit of time:

Let $P_1$ be the absolute pressure of the atmosphere.

$P_2$ be the absolute pressure, equivalent to the head of submersion of the foot-piece.

$V_1$ be the volume of air delivered per second to the pump, measured at pressure $P_1$, and a temperature equal to that of the liquid being pumped.

$x$ be the distance of the point under consideration above the point of air injection in feet.

L be the distance in feet from the point of air injection vertically to the outlet of the eduction-pipe.

The same weight of air, and likewise the same weight of water must pass each point of the eduction-pipe per unit of time; the volume of air flowing per second through the outlet of the pump is $V_1$ cubic feet, and the volume of air entering the eduction-pipe during the interval is $V\frac{P_1}{P}$. The increase of volume of the air in ascending the eduction-pipe is—

$$V_1 \left(1-\frac{P_1}{P}\right),$$

and the total volume of air passing the point under consideration per unit of time is—

$$V\frac{P}{P} - \frac{x}{L}V\left(1-\frac{P}{P}\right).$$

The sum of the volume of air and water passing per second being thus found and cross-sectional area of the pipe being known, the average velocity can be calculated. This average of what is in some cases a widely varying quantity is the only value that can be calculated, and forms a very valuable deduction in analyzing the results of tests and in designing the pipe for a new installation. In cases where the air is injected in the form of small bubbles, and the pump is run at or over its most economical capacity, the velocity at any point appears to remain fairly uniform, and as has been pointed out above, these conditions should exist in a well-designed pump; therefore the average velocity calculated by the above method will be a close approximation to the true value. (To be continued.)

## RUST PREVENTATIVE

By M. M.

A NEW rust-proofing for electrical or other machines is an application to the surface of the iron or steel of iron phosphates, which are insoluble and not corroded under ordinary conditions. After thorough cleansing, a bath containing ferric and ferrous phosphates is prepared and the articles immersed therein, and then a little manganese dioxide is added at boiling water temperature. The articles are left in the bath until hydrogen is no longer given off. The articles are then air-dried, when they may be treated with mineral oil or painted, japanned or otherwise finished. As the phosphate surface is attached chemically to the metal no rust forms even in cracks in the paint.

## PRESERVATION OF TEST FRACTURES

By M. E.

A clear coat preservative varnish to protect bright articles is sold under various trade or fancy registered names. A chemist friend advises that although various brands are on sale they are all more or less identical, consisting of a solution of celluloid in amyl-acetate. Further, that if by exposure thinning is required, the addition of amyl-acetate acts similarly to turps in ordinary paint; he also suggests that for many purposes the bought material is profitably thinned down. Those who have used the material do not need to be reminded of the characteristic pear drop smell and pungent odor evident. One of the most annoying things about the retention of ferrous test specimens is that if the fracture is exposed, a few days suffices to spoil its appearance, and indeed, the fractured surface seems peculiarly liable to rust.

Tin foil pressed well home is some protection, but it is by no means ideal. The marketed compound previously referred to has many advantages for the purposes indicated, and is superior to any other method. If a small tin of the substance is available and the fractured portion of the specimen dipped bodily as soon as pulled, the excess being ejected by a sharp movement, it dims the lustre of the break very slightly, but allows preservation for months without corrosion or alteration. The effect of the solution does not in the least impair the characteristic features of the break. The evaporative quality of the amyl-acetate is very rapid, and a few minutes only is needed to dry out; the protective coat then left is a thin film of transparent celluloid. It is more than probable that the brilliantly-colored protective coatings now much in evidence for bright goods have a similar basis, the color being added merely to make visible the treatment. It is understood that the preparation of the compound is by no means difficult, and involves nothing more than dissolving celluloid in the evaporative media. However, the value of the translucent solution is particularly great in the instance quoted, and the value of a material for the protection of bright work which does not alter appearance is worth notice. As it can be procured in small quantities at most cycle accessory dealers, it is quite commercial and convenient for use.

## MECHANICAL ECONOMIZERS

By K. M. E.

THE greatest advances of the past decades have been made in the basic field of the raw materials of mechanism. Modern metallurgy, for example, has made enormous strides, and grows less and less dependent upon initial material of high relative purity. This has set free large quantities of low grade material hitherto not utilizable for highest quality of products, and recently it has been found expedient to allow higher percentage of deleterious ingredients to increase production. The increase in permissible contents of phosphorous and sulphur in steel has not been attended with any visible ill-effects, provided always that circumstances condition use. Thus the field of supply has been extended in a double sense with benefit all round.

Hand-in-hand more modern organization serves to give increased individual production, while productive means themselves have been also improved. The economies of waste by its limitation have also been duly studied, and especially process economy in material has been duly enhanced in importance. Practically at every point of the compass the saving virtue of thrift imposed by real necessity has served to give benefits, whose ultimate outcome is difficult to foresee. Elimination of waste, the utilization of inferior raw material without detriment to the finished product, greater ingenuity in mechanism itself, better organization, increased specialization, economy of material itself, substitution of one material for another, all these make productive engineering a field of surpassing interest which will increase rather than diminish in the future.

Problem after problem has been attacked and made to yield some economic result. The entire art of metal working from first to last is altering visibly year by year; at no point is it stable or lacks definite improvement, and no detail is so small as to escape analysis in competent hands. It is quite possible that in the near future iron castings will give way to steel in a universal sense, while the electrical furnace will shift the centre of gravity of the steel trade to new quarters.

To attempt the enunciation of the economic value of all the advances made would be extremely difficult, but as a total they must be immense. Their full exploitation may indeed so enable productive costs to be cut that increased average wages will not hamper the profits of industry and solve the most difficult of all the outstanding problems—that of labor.

# Underlying Principles of Forging Machine Die Design--II.

By F. R. Frost.*

*Abstract: [illegible] are familiar with successful practice.*

tool begins to upset the stock, it will, of course, buckle at "T," but being supported by the die at this point, and by virtue of the fact that the friction along the side of the die will cause the forward end to upset first, the stock will gradually carry back in the die and produce a uniform upset, as shown by Fig. 43. The use of this method is also indicated in Figs. 44, 45 and 46.

### Limit to Heading Tool Travel

RULE No. 3. In an upset requiring more than three diameters of stock in length, and in which the diameter of the upset is one and one-half times the diameter of the bar, the amount of unsupported stock beyond the face of the die must not exceed one diameter of the stock.

This rule, as will be noted, is a combination of Rules 1 and 2. As an example, if the stock to be upset, as in Fig. 47, is 1 inch diameter by 6 inches long, and the diameter of the hole in the die is 1½ inches, then the amount of stock as at "U," extending beyond the face of the die must not be more than 1 inch.

However, if the diameter of the hole in the die, as in Fig. 48, is reduced below one and one-half diameters, then the length of the unsupported stock beyond the face of the die can be correspondingly increased. If the diameter of the hole in the die is not over one and one-fourth times the diameter of the stock, then the amount of stock beyond the face of the die may be increased to one and one-half times the diameter of the bar.

This rule also applies to cases where the upsetting takes place in either straight or taper holes in the heading tools, as in Figs. 49 and 50. If an effort is made to allow a greater amount of stock unsupported beyond the face of the dies, as in Fig. 51, the stock will buckle outside of the dies, as shown in Fig. 52.

It will be readily seen that such a limited travel of the heading tool as at "U," Fig. 47, would not provide sufficient stock to entirely fill the impression in the die, hence in

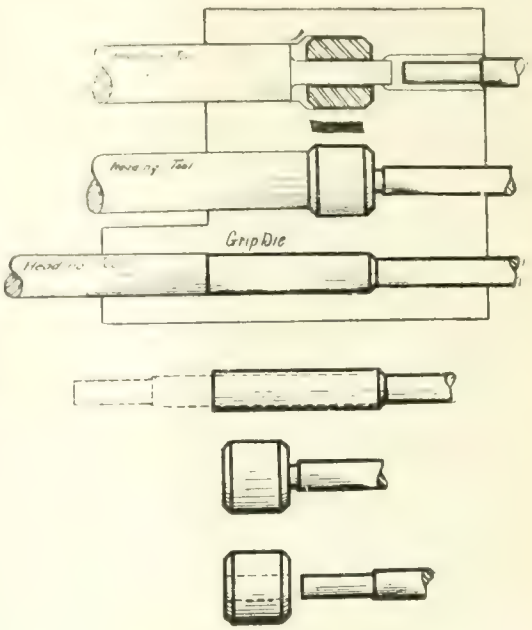

FIGURE 45.

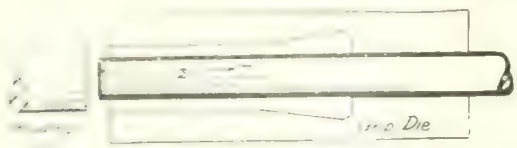

FIGURE 42.

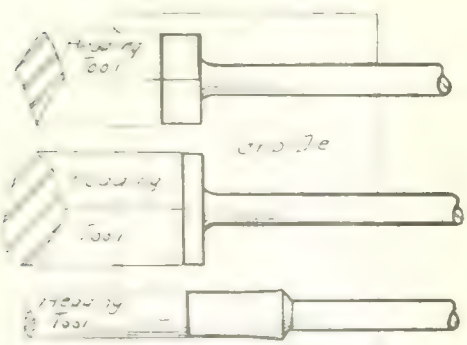
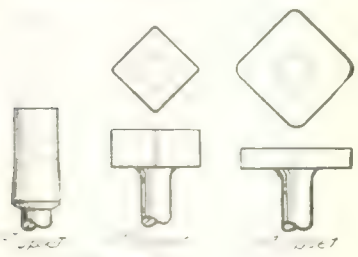
FIGURE 43.





view of the limited heading tool travel on account of rule No. 3, many upsets can to advantage be made tapering, as indicated in Fig. 53.

The taper upset possesses many valuable qualifications, particularly in that if the angle of the taper is approximately four degrees on each side, as indicated in Fig. 53, the increased diameter of the upset, as the heading tool advances, increases the pressure in the direction of the bottom of the impression in the taper tool, and more fully insures a uniform and well filled upset.

Fig. 54 shows how progressive taper upsets can be made, keeping in mind in each case that the diameter of the taper hole near the middle of the unsupported portion of the stock must be kept within the requirement

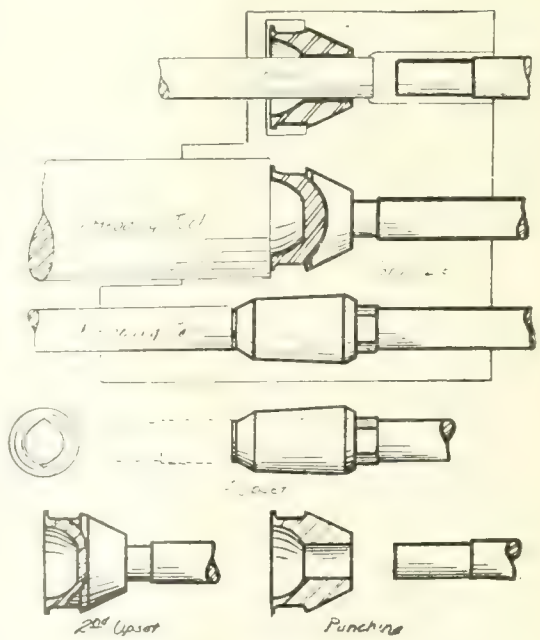


FIGURE 46.

FIGURE 47.

of Rule No. 2. A large amount of stock can be gathered in few operations by this method, for while the first die impression is limited to the size of the bar, thereafter it is the dimensions of the taper upset that governs the size of the next die impression, and not the diameter of the bar.

The taper upset is also valuable in properly distributing the stock at desired points, such as at the base of the final upsets in Figs. 55 and 56; in more easily filling a large flange, as in Fig. 51; or, by inverting the taper, securing the advantage of filling the outer flange, and enabling the second forming tool to more easily place the stock, as in Fig. 58.

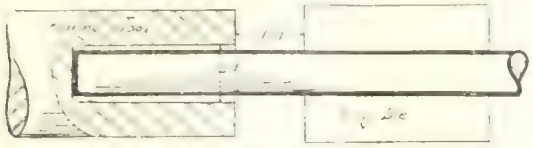

FIGURE 48.

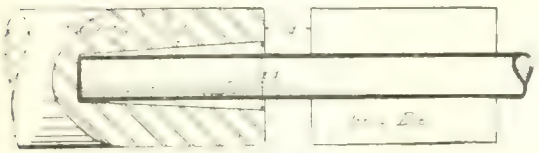

FIGURE 49.

FIGURE 50.

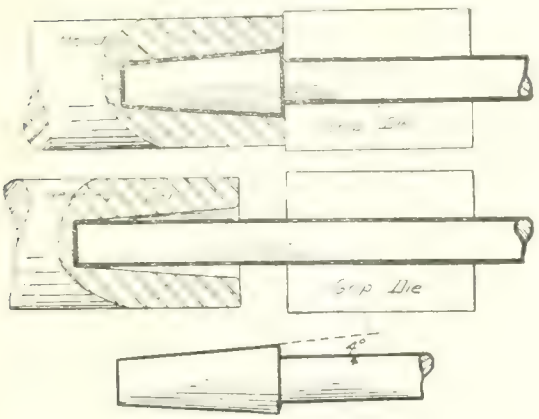

FIGURE 53.

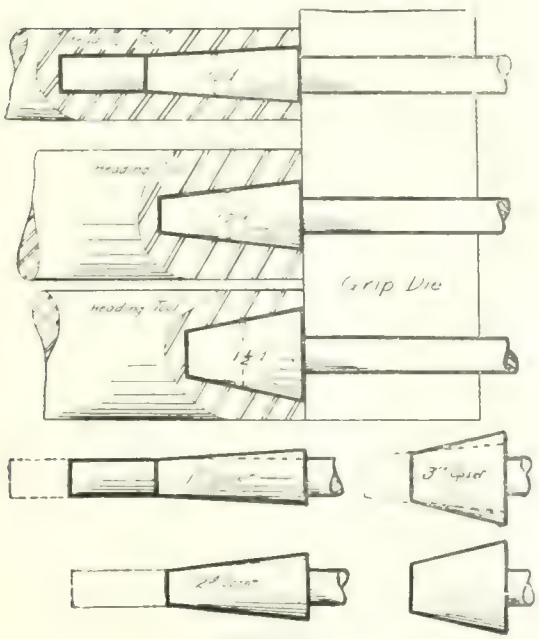

FIGURE 54.

Another form of die having great possibilities, but whose limits are more frequently misunderstood, is the sliding die, as shown in Fig. 59. Such dies are, of course, in quite general use; and are invaluable in upsetting stock at a considerable distance from the end of a bar. Rule No. 1, however, is still with us, as the total length of unsupported stock, measured from the bottom of the die impressions as at "V," must not exceed three diameters of the bar.

The practical application of this form of die is shown in Figs. 60 and 61.

In case the length of unsupported stock is more than three diameters, as shown in Fig. 62, then both rules 2 and 3 must be kept in mind as applying to the relative diameter of the upset, as at "W," and the length of stock extending beyond the face of the die, as at "X."

Fig. 63 represents a failure in a sliding die, as the middle of the stock, being beyond the face of the die, and hence unsupported, would buckle, the same as indicated in Fig. 64.

In any extensive application of the sliding die, it is generally necessary to gather stock in several impressions, and here not only must Rules 2 and 3 be kept in mind, but the fact remembered that the friction along the side of the die will cause the upsetting to take place near the front end of the die. For this reason, if the first upset is formed in the rear half of the dies, then the second impression should be in the front half; the third impression in the rear half; the fourth impression in the front half, etc., in order in each case to bring that portion of the upset which naturally swells the most into the bottom of the next impression where is is more difficult to carry it. The idea is shown in Fig. 65.

In the application of the sliding die, Fig. 66, an upset is made in the sliding portion of the die, and another at the front face of the die at the same stroke of the machine.

Fig. 67 represents a double sliding die, in which two upsets are formed in the

FIGURE 51.

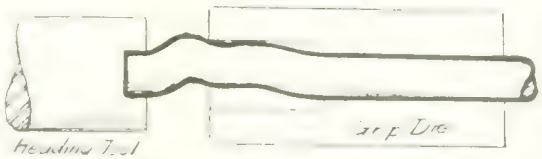

FIGURE 52.

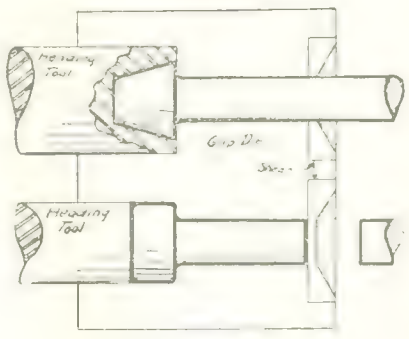
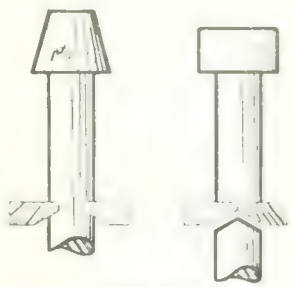
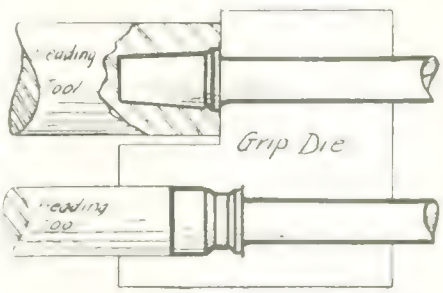




FIGURE



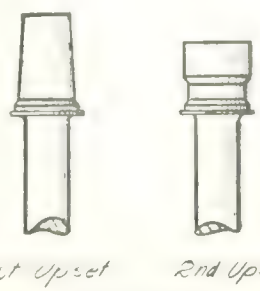


FIGURE 56.

ing die, in which the stock is gathered in the first impression, and the forging is practically cut from the bar. Upon being lowered to the final impression, the upsetting is completed, and as the bar is turned one-fourth of a revolution the forging is severed completely from the bar.

## EXTRUDED METAL

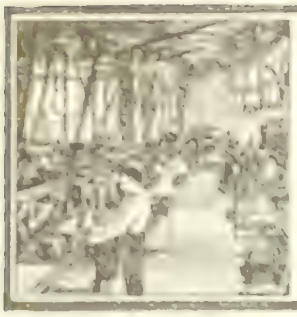
By M. L.

Metal wire and rod made by the extrusion process is coming more and more into common use. For many years wire and rod have been made by the drawing process in which the metal is pulled through dies, successively reducing its diameter or shape. Volume of production was limited at first by the time consumed in attempting to reduce the wire too much at one draft, which resulted in pulling the metal apart, and in the frequent annealings necessary to soften the wire.

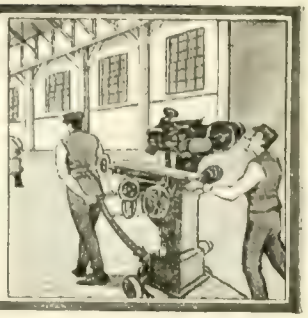
By the extrusion process the metal is pushed through the die while quite hot, thus overcoming at once the two limiting conditions of wire-drawing. The wire does not break because it is pushed through the die, and it does not get hard because it retains its softening temperature during the extruding. The process has been used in producing lead wire and lead pipe for a number of years. The problem of extruding lead, however, presents very few difficulties, as the softness of the lead allows it to be forced through the steel die cold.

For lead extrusion, the necessary equipment consists of a multiple plunger pump, a hydraulic accumulator, and a hydraulic press with attachments. Briefly these attachments consist of a heavy steel cylinder with a die-holding arrangement on one end, the other end being open to form a close fit to the plunger or ram of the hydraulic press. In extruding lead wire, a larger piece of lead is placed within this cylinder and the press started. Lead wire will flow continuously from the hole in the die until the ram reaches the end of its stroke; it is then withdrawn for a new supply of lead. During the two strokes of the ram there occurs no break to the lead wire, the second supply of lead welding perfectly to what remains of the initial charge. In producing lead pipe a long arbor is used, the point of which enters the die in such a way as to form a ring-shaped nozzle, which determines the cross section of the pipe.

Recognizing the possibilities of this process, experiments were made with the object of producing brass rod and wire by the extrusion process. Difficulties at once arose. It was found that to secure desired results all the metal must be quite hot during the extruding, that hydraulic presses of great power were necessary, and that dies suitable for lead extrusion would not withstand the temperatures essential to successful results. These difficulties have, however, been overcome and a number of firms are now making brass rod by the extrusion process. A valuable feature of this process is the practicability of extruding the brass through odd-shaped dies to form certain cross-sections very expensive to obtain by other methods.



# DEVELOPMENTS IN SHOP EQUIPMENT



*Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

### MOTOR DRIVEN DRILL AND TAPPER

[illegible] without danger to machine or operators is the purpose of the new Barnes self-oiling, all geared drill and tapper which handles high speed twist drills from ½ inch to 2 inches.

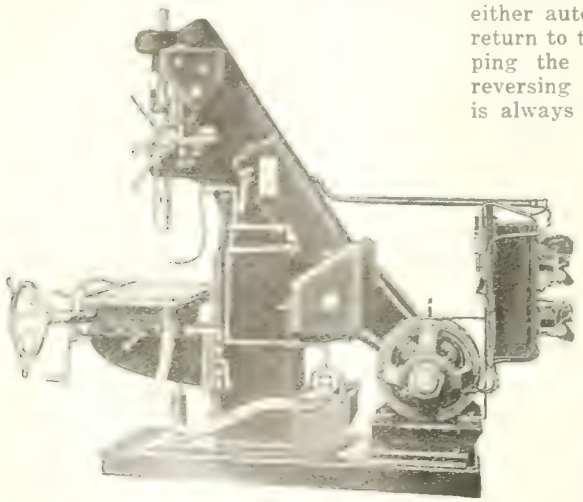
[illegible] machine, built for heavy-duty work and rapid production. Belts are entirely eliminated, all power being transmitted through gears. With the exception of the spindle sleeve and cross spindles, all bearings and all gears are continuously lubricated by an automatic self-oiling [illegible] pumped from the reservoir at the base of the machine by a geared pump.

Eight changes of speed are provided, with control levers within easy reach of the operator from his position in front of the drill. The spindle may be stopped by placing the shifter lever on the neutral position, or by throwing out the clutch gear. All transmission gears except the friction clutch gears are cut from special high-grade chrome nickel steel, heat-treated, and tempered to prevent wear, and to increase strength and stiffness.

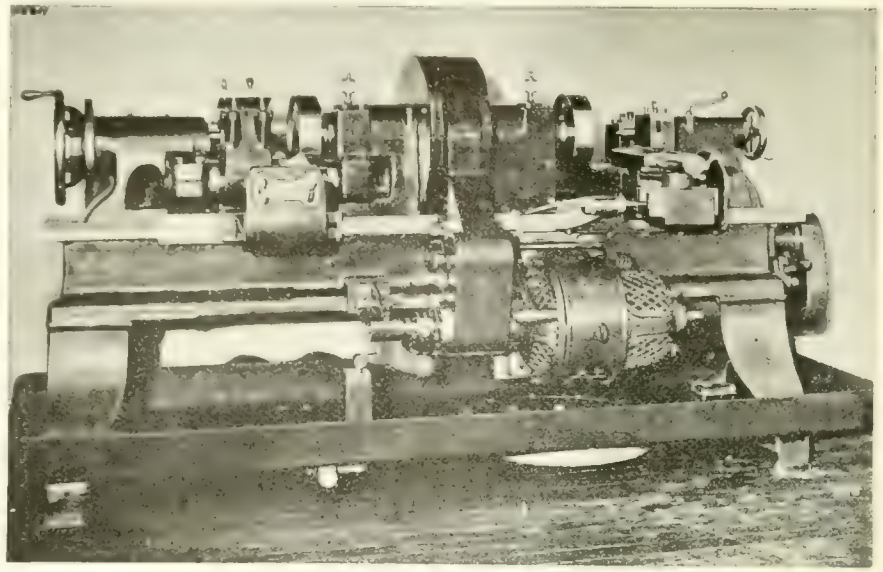
There are ten instant changes of geared feeds, controlled by levers directly in front of the operator. The feeds are indicated in plain figures on an index dial plate. All important feed gears are cut from steel and are case-hardened. A safety collar protects the machine against damage from overloads.

For tapping, the machine may be equipped with an automatic reversing mechanism, which is very desirable, especially for depth tapping. A trip on this mechanism can be set so that the instant the tap reaches the depth required, the spindle will automatically reverse. It is also possible to set the shifting lever so that when tripped, either automatically or by hand, it will return to the neutral position, thus stopping the spindle instantly instead of reversing it. A small hand trip lever is always ready for use if it is desired to stop or reverse the spindle at any point in the operation.

These machines are driven through a silent chain by a Westinghouse 10 h.p. direct-current motor provided with a Westinghouse automatic starting panel. This panel is shown exposed in the illustration, but is provided with a metal case when desired. All gears are entirely enclosed, meeting the requirements of modern safety laws.



[illegible] AND TAPER.



CENTER DRIVE LATHE.

### CENTER DRIVE LATHE

The center drive lathe, shown herewith, was originally designed for the Ford Motor Company, for turning both ends of the driving shaft simultaneously.

The work is passed through an opening in the left hand tail-stock, which opening is brought into position by indexing the barrel of the tail-stock 180°, at which position the work passes direct into the spindle in the head-stock. After the work has been passed through the tail-stock, the tail spindle is again indexed at 180°, which then brings the center into position.

The work is then mounted on the centers, after which the chucks (which are of the floating type), are bound or clamped to the work. The chucks are then secured to the driving plate.

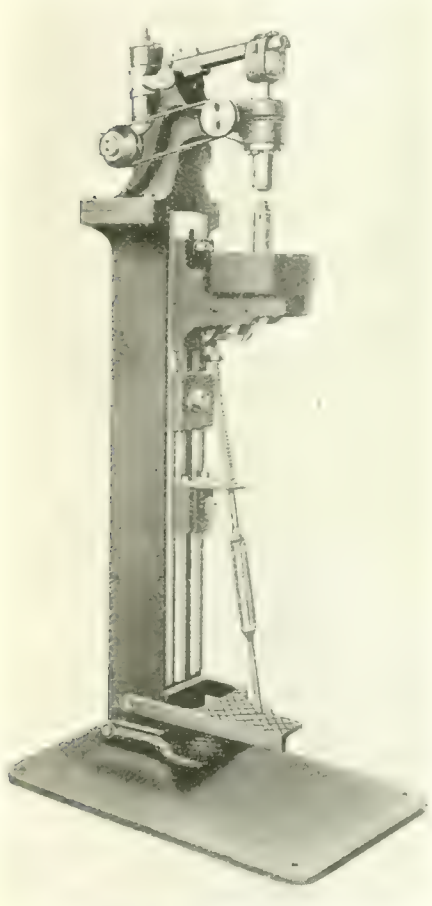
When the machine is started, two carriages feed toward the center of the headstock, thereby turning the various diameters at each end of the work, as well as the outer portion.

While this diameter-turning is in progress, the back arm tools are simultaneously squaring down the shoulders which are necessary on the shaft. The action of the carriage transmits radial motion to the back arm block, which mo-

tion is obtained through the medium of the cam-slot, which is secured to a bracket, fastened to the rear of the carriage.

An extension arm with a roller, which is in contact with the path cam, is secured to the back arm bar and block, from which relationship it will readily be seen that the length of the cam in its longitudinal travel along the bed must necessarily create a rocking or radial action to the back arm block and tools, thereby performing the squaring operation.

This machine is being driven by a Westinghouse type 5 h.p. SK motor, which runs at 1,100 r.p.m., and the stopping and the starting of the spindle



MACHINE FOR BURR-RIVETTING.

is obtained through the medium of an internal expanding clutch provided on an extension of the motor shaft. The drive from the motor to the head spindle is through a set of sprockets and a Morse silent chain, and an idler pulley is provided to take up the slack.

These machines have proved very successful in the factory of the Ford Motor Company. They were designed and manufactured by the Reed-Prentice Company of Worcester, Mass.

**Working at Midland.**—A syndicate contemplates the establishment of a plate mill at Midland, also improvements to the shipbuilding plants.

## COPPER RIVET HEADING MACHINE

THE machine shown in the accompanying engraving has been designed by the High-Speed Hammer Co., Rochester, N.Y., to facilitate the heading of the copper rivets used in holding heavy harness together.

This high-speed riveting hammer compresses the work, holding the washer or burr tightly to the work during the riveting operation, and produces a dependable, finished head on the rivet without swelling or bending the rivet shank, accomplishing the whole operation at the rate of about two seconds per rivet head.

The hammer strikes 2,600 blows per minute without subjecting the operator to strain or shock.

Two-foot treadles are provided, pressure on the top one compresses and centers the work, pressure on the lower one causes the peining tool to form the finished had with a rapid succession of flexible rotary blows, which are delivered through the centering sleeve.

## CALLING SYSTEMS

FOR quickly locating officials or employees in factories or other large buildings, telephones and office boys are inefficient and unsatisfactory; they take too much time and bother a lot of people unnecessarily. By the installation of the calling system illustrated herewith and manufactured by the Standard Electric Time Co., Springfield, Mass., much of this trouble is avoided.

The calling instrument is fitted with telephone type-ringing keys, and furnishes any number of codes desired. The regular model gives forty-five different numbers. These various numbers are secured by merely pressing down keys as indicated in the cut. Automatic control is secured with the electric starting device on the extreme right end of the instrument. Depressing this key gives three rounds of the number or continuously as desired. The instrument can also be started manually by the plunger shown on the top of the case.

The instrument is furnished in a neat oak case, and is of such compact size that it can be placed upon the telephone desk or similar location. If the system is to have extensive use, the signals should be operated from 110-volt AC or DC current, or with a large battery system, in which case a relay must be used with the instrument to break the current. Both instrument and relay are wound to operate from 24-volt battery current. The relay is designed to break considerable current with very little arcing. It is mounted on a slate base and enclosed in steel case.

A great variety of signals can be used comprising vibrating horns, motor horns, buzzers and vibrating polarized or single stroke bells and gongs with 110-volt current. With ordinary battery voltage high wound vibrating bells serve well. All signals should be carefully selected according to the noise conditions. It is wise also to take note where the machinery noise tends toward a bell tone or a horn tone. For instance, some noisy machines make a sound very similar to a horn; in such departments loud gongs will be more easily heard, whereas if the machinery makes a ringing, metallic sound the horn will be more effective. For industrial plants an ideal arrangement consists of the automatic calling system and a master clock with automatic program attachment. The latter will sound the working hours of the plant and utilize the same signals and wiring of the calling system, thereby giving greater value for the investment cost. There is no possible confusion between the two, because the calling instrument gives a very quick, short ring, whereas the program clock has a long three to to five-second ring. Inasmuch as the signals are located throughout the plant in all departments this furnishes an ideal starting and dismissal signal very much more satisfactory than the ordinary steam whistle blast. This equipment

CALLING INSTRUMENT.

also lends itself to a further advantage of providing not only single, but double and triple rings if desired. For instance, one ring can be used for wash-up signal, two rings for dismisal, or one ring for male help, two rings for female help, etc. The master and program clock will be furnished wound to operate properly from the same battery used for the calling instrument and relay. It is entirely automatic and exceedingly accurate and reliable.

THERE has recently appeared upon the commercial market an anti-friction alloy which is made by impregnating graphite with molten metal under hydraulic pressure. By this method the high lubricating nature of graphite is combined with the mechanical strength of the metal used, and the resulting alloy has been found to possess many desirable properties which tend to give a very promising future in the realm of mechanics. While bearings made of this substance must of necessity be restricted to a limited size, their manufacture forms a practical and noteworthy achievement in the great field of scientific endeavor.

Vol. XIX. MAY 23, 1918 No. 21

## IS THE STEEL TRADE DUE FOR A REACTION?

ONE of the features of Britain's industrial effort since 1914 has been the expansion of the steel industry. From seven to twelve millions of tons is a large increase at any time, and when the latter was announced last year, reference was made to further increases expected.

That these further increases would be accompanied by an increase in price was hardly to be expected, yet reference is made in recent advices from Britain to an evident agitation for an increase in maximum prices, while at the same time some concern is being displayed regarding the future demand for so much steel and iron. There may be some commercial politics at work behind the two activities, but an interesting feature of the case which is not disputed is the large supply of high speed steel which is now available.

English makers of high-speed steel who have been accustomed to receive orders greatly in excess of their capacity have now caught up with the demand, many of them actually reporting that new orders are not keeping up with production. The London *Ironmonger* states that conditions are intensified by the return to Sheffield from various seaports of large quantities of high-grade steel which had been purchased for shipment to Russia. In addition to the loss of that market it is understood that France and Italy are extending their home manufacture of tool steel and require less from Sheffield; there is also a heavy drop in the consumption of the shell shops and export trade has been reduced to a minimum by Government regulation.

Just how long the latter feature will obtain is at present a matter of conjecture but it is reasonable to expect that Canadian built and owned ships will be allowed to remove some proportion of a surplus essential like high-speed steel and the re-appearance of this material of English manufacture should not be unlikely. Its return is at least desirable to the extent to which it may forestall and prevent the revival of such business with German firms at a later date.

## EFFICIENCY IS NOT ALWAYS PROGRESS

DURING recent years the word efficiency has attained a widespread notoriety, having been used and misused with a frequency only equalled by that later arrival, "camouflage."

The outstanding example of efficiency extraordinary is of course the German nation. It is also a convincing demonstration that there are limits to the development of efficiency beyond which it is not safe to go.

The efficiency curve of a nation as shown by the Hun tragedy is somewhat akin to the characteristic curve of a shunt-wound dynamo. Up to a certain point an increase in load is accompanied by an increase in output, but when the peak is passed the curve droops with increasing rapidity. A further increase in load means a disastrous drop in output accompanied by failure of the machine to generate.

Students of the situation, especially with reference to industrial conditions, will doubtless agree with a recent utterance by a certain Englishman who said: "We are now undergoing a phase of reaction against efficiency. A few years ago we were all for efficiency, and especially for German efficiency; but now, when we see the effect of efficiency on a great nation which had set itself to govern the whole world and had lost its own soul, there was reaction against an efficiency which might lead to such disastrous moral results."

Progress, however, viewed in the light that it places happiness and contentment above material accomplishment, is a higher ideal than straight mechanical efficiency which is an admirable feature of machinery but becomes repulsive when applied too strictly to human beings.

Modern science enables machines to be made which are exact duplicates of each other in ability as well as dimensions. Man, a creature of flesh and blood, has variations in these respects which form the real bond of union and human interest amongst the inhabitants of the world. The moment an attempt is made to level out the efforts and demands on men just so soon does progress come to a standstill.

As remarked by a contemporary, "We cannot avoid the conviction that the mechanics of the past, who were masters of craft, were more human than will be the mechanics of the future, brought up to perform for a few hours a day one simple operation, and one only. We doubt, indeed, if the fact that they will enjoy more leisure will ever quite counterbalance the dwarfing effect of performing for five or six hours a day an operation compared to which squeegeeing the mud off a pavement is a high art.

## SHIPBUILDING EXPERIMENTS PROCEED APACE

DURING the past twenty years more progress has been made in the fundamental branches of marine engineering than in the preceding twenty centuries. Metal hulls and reciprocating steam engines marked the high tide of progress, the methods of design and construction being well standardized at the close of the nineteenth century.

Gradually, however, the wave of evolution began to accumulate momentum again: steam turbines, alone or combined with engines; then gear drives, mechanical, hydraulic and electrical; internal combustion engines; new hull systems, saving material and increasing strength; all followed each other with great rapidity.

Most spectacular, perhaps, has been the development of the concrete ship from a latent state of freakishness to the status of a large industry destined to influence the result of the present struggle.

The necessity for speed and economy in ship construction has enabled consideration to be given to almost any idea which promises to reduce cost and increase output, and the use of electric welding on a large scale for hull construction is now being exhaustively investigated at one of the leading shipyards in the New York district. Part of a full size hull will be constructed, three-quarters of the work being riveted to afford comparison with the welded work. Testing will be done very completely, including shifting loads while partially submerged, as well as abuse by bumping and ramming.

Time and cost on a 10,000-ton ship are expected to be reduced by one month and $40 a ton, due to abolishing or greatly reducing the railroad journey from rolling mill to fabricating plant when the latter is not at the shipyard; the templet maker's work; the marker's work; the punching; the work of fitting the plates ready for riveting.

These items apply in considerable measure to present conditions in Canada. The large resources of electrical energy may well be utilized in work of this nature when munitions have waned and the results of the test will be awaited with more than ordinary interest.

# MARKET DEVELOPMENTS

# War Work Now on a Scale Larger Than Ever

## Business of Munitions Going Ahead as Though War Were Sure to Last For Long Time Yet—New Shops Being Rushed to Completion to Handle Contracts on Very Large Scale—Prices Remain Firm in Nearly All Lines

THE rumour in the Street has it that price-fixing has been considered by the War Trade Board at Ottawa, and that many obstacles have been found in the way. The chiefest of these would no doubt be the fact that the measure would in effect amount to fixing the price on something that is not produced in this country. Dealers are not worried over the possibility, and contend that the business is almost entirely under Government control now, regarding the avenues in which trade shall be directed, etc.

Signs continue to increase that the machine tool trade recognize the war business as being on a more permanent basis now than for some time past. One Toronto manufacturer is going ahead turning out a batch of 25 heavy special tools that are applicable for war work only. He has not made a sale yet, nor does he want to until his machines are all on the floor ready for delivery. It can readily be surmised though that this firm does not consider it likely that the war work will wind up quickly.

The demand for machine tools and for supplies, for carbon and high speed material is brisk. New plants that will not machine a shell for two months yet are in the course of building to handle new contracts on a scale that has not been known in the past.

Scrap metal dealers find themselves in the position of being able to secure large supplies of the non-ferrous metals, for which there is not the keenest demand at the moment. The result is that their yards are being well stocked, but they lack the materials that are called for now in the munitions plants where they are turning out the makings of shell blanks.

Drawings of the new 155-mm. shell are being studied by the firms here. There is a tendency now to make the walls of the shells being turned out now thinner than those previously made. The idea of the ordnance experts apparently is that the thinner wall will break into many more pieces than the thicker one of the older type shells. Pieces returned from the battle front frequently show a base with a large piece of the wall attached to it, whereas it is claimed shells with thinner walls would have broken into pieces, and added to their destructive force many fold.

## ONLY THE WAR TRADE IS SERVED BY FIRMS MAKING MACHINE TOOLS

Special to CANADIAN MACHINERY.

MONTREAL, Que., May 21, 1918.—Resumption of the munitions activity throughout Canada has occupied the attention of Canadian manufacturers for the past few weeks. Several large firms have recently obtained orders for different sized shells, and in some instances new plants will be erected to handle the additional business. The most recent contracts call for large shells for naval purposes. Considerable difficulty is still experienced in obtaining machine tools, as the general demand at present is quite heavy. A local firm of engineers has recently purchased a plant for the purpose of manufacturing a line of Scotch pumps that have previously been imported, and which at the present are almost impossible to secure owing to the restrictions placed on such equipment coming from Britain. Local activity in every line of industry is quite brisk, and particularly so in connection with shipbuilding. Two wooden vessels of 3,000 tons each are expected to be launched from the yards of the Fraser, Brace Co., and in the near future two or more steel vessels from the yard of the Canadian Vickers. The feature of the present situation is the almost total elimination of all activity other than that required to carry on the war. The acute condition of steel may be soon recognized by the Ottawa authorities as a basis of some sort of regulation and price control.

### Steel

Conditions in the local steel situation have shown little variation from those of the past few weeks, and the general market is quiet, although business is carried on in considerable volume, but through the medium of the Government, very little ordinary business being recorded. Local mills are all working to capacity, and while some of the output is available for domestic requirements, the greater portion is utilized for war purposes. Manufacturers requiring to obtain steel from the States have been experiencing increased difficulty in getting supplies through owing to the increasing demands across the line and the inability of the railroads to provide adequate facilities for the desired transportation. Some of the American plants have had to curtail their output owing to the necessity of diverting material to keep the more essential industries operating nearer to capacity; this condition is becoming more emphasized, particularly in respect to some of the smaller establishments, and it is anticipated that in the near future some of these will have to still further curtail or cease operating entirely, at least for a temporary period. The summer months have always been a signal for reduced production, and with the pressure that will undoubtedly continue it is very apparent that the steel situation may develop a still more acute position than that of the present. It is not unlikely that some action may be taken by the authorities at Ottawa towards a better regulation of conditions here in Canada, but so far little is known among the local dealers in this connection. Dealers report a quiet market, with activity confined to war work exclusively. No price changes are announced, and those quoted are of a nominal character.

**Copper.**—The local situation is not

marked by any pronounced shortage and the requirements for essential war necessities are ample, but the available supply for domestic consumption is not great. However, this is of little importance, as little work of an ordinary character is now carried on. Local quotations are still firm at 29c and 30c per lb.

**Tin.**—The acute and uncertain position of tin is still pronounced. The situation regarding the supplies from Dutch sources has shown little improvement, and while the London market has developed an easier tendency the same has not yet been reflected in the United States or Canada. Local dealers report the demand restricted to essential requirements, and metal is only sold to those in urgent need of it. The quotation of $1.25 is still strong on the local market.

**Spelter.**—Despite the recent advance in the price of spelter the demand that was anticipated has not materialized and the trade are apparently not disturbed over the strength of the past week. The buying is normal but not sufficient to indicate that the advance will be anything but slight, and dealers here do not look for any pronounced demand at present; quotations are unchanged and firm at 10 cents per pound.

### Machine Tools and Supplies

Many local firms in the market for machine tools are having considerable difficulty in obtaining such as will meet their present requirements, and where new tools are required it is often necessary to wait from six to eight months for delivery with the possibility that even then the machines may be diverted for other and more urgent purposes. Apart from the orders that are being placed for standard equipment the general demand for tools at the present time is of a special nature, with the consequence that the machines must be built from the design upwards, the standard patterns and parts being unsuited to the existing requirements. Munitions firms that have recently received shell contracts are now rapidly preparing for their production, one large firm here has received an order for 9.2 inch shells which will run into several million dollars. Another large local firm expects to build a new plant in the east end to handle additional large orders. This latter firm has already contracted for a considerable volume of machinery from a local firm and the production of this is proceeding as rapidly as possible. In this respect it might be mentioned that mechanics are becoming more difficult to secure and manufacturers are seriously handicapped in getting out the tools so urgently required. Activity in all kinds of supplies has been stimulated by recent developments and machine shop accessories are in increased demand both for munition plants and for other lines of industry. Prices in many instances have shown an increase.

### Scrap

Business in old materials is relatively quiet at present and dealers are apparently carrying little stock other than that required to supply the needs of regular customers. The feeling of uncertainty that has characterized this market for some weeks is still a feature of existing conditions, and local dealers report a tendency of nervousness; few price changes are recorded, but slight fluctuations have taken place during the past week. Machine cast iron is strong and in good demand, but the nominal quotation of $31 is the price given by dealers here. Some dealers are looking forward to higher prices on scrap copper.

## POINTS IN WEEK'S MARKETING NOTES

**The plant of the Dominion Iron & Steel Co. at Sydney, N.S., is rolling rails on order for the Government, and is turning out very little sheet steel for the present.**

—

**Labor trouble over wages has not been finally adjusted at Nova Scotia mills, although large increases have been granted to the men since the first of the year.**

—

**The "steel market" has almost ceased to exist at some big points, as the output automatically goes to war purposes, and the balance to orders that have been on the books for a long time.**

—

**Steel mills are making big money in the United States, and the opinion is expressed that the Government may use this to force a lower fixed price after July 1, or increase the war profits tax on the operations.**

—

**A good supply of coke for making pig iron is looked for following the completion of the work on the new ovens at Sydney.**

—

**Steel ingot production for April at United States mills was at the highest ratio yet reached.**

—

**The United States Government arsenal on Neville Island calls for an expenditure of about $40,000,000.**

—

**Rumors heard on the street, and which also are heard in Ottawa, have it that price fixing in Canada, on the plan adopted in United States, has been considered at Ottawa.**

—

**Ontario dealers are turning more to the Nova Scotia mills for steel output, as it becomes harder to secure a supply from the usual sources of supply in United States.**

## NEW EQUIPMENT FOR THE WAR ORDER SHOPS

**This Is Being Turned Out at a Greater Rate Than For Some Time Past**

TORONTO, May 23.—Business in the iron and steel trade is getting to the point where close students of the situation claim it should have been two or three years ago, viz., under control, the motive of the control being the prompt supplying of essential industries with material and the cutting-off of the non-essential lines with equal promptitude. More and more the war rule is being put alongside every bit of business that comes to the market. Not in one place, but in several—with the jobber, the Government and the mills. All these points have to be satisfied that the work is going to assist in the winning of the war, and if this cannot be done, the order stands little or no chance of receiving any attention whatever.

The sequence of events would bring the control of prices in very close relation to the steps that have already been taken, and there are many in the trade who are inclined to welcome such a step, as they can see that the trend of events has been moving in that direction. The big difficulty is that price control is not directly in the hands of the Canadian Government, because the great bulk of material handled here is imported from the rollers across the line, and obstacles might arise in the way on that account. The matter, though, is being discussed, and there is good authority for stating that it has been discussed by the War Board at Ottawa. It's a big question though, and will probably need a lot of discussion before action is taken. Men in the trade are not disturbed about the rumors of price regulation, pointing out that their business now is practically in the hands of the War Department regarding its scope and activity.

Scrap yards are beginning to pile up with metals that are not called for by the war industries. For the lines used in munitions output there is a brisk demand and a scarcity. For the non-war lines there is little demand. This state of affairs is not likely to be remedied as long as the war grip remains on the industrial life of the country. Prices remain the same as quoted a week ago.

### Steel Prices Firm

Steel prices have not advanced as the result of the order that no purchasing shall be done for warehouse purposes, but there is a strong tendency in that direction, and in some quarters a higher price is quoted on plates, but the increase is not quoted locally yet. Black sheets No. 28 are given at $7.75 to-day, being 25c per hundred off the previous price which has been in effect for some time. Premier galvanized No. 28 U. S. are $8.70, against $8.95, and the 10¾ oz. are given as $9, in both instances being a 25c per hundred pounds reduction.

"I do not put much stock in the talk of price control," remarked one jobber today. "It is like trying to control the price of something that we do not own.

[illegible] Scotia." Other dealers were inclined to look at the thing differently. "I believe [illegible]" was the opinion of another dealer. "It would have to be brought about by the Government or the trade boards of the two countries, but they regulate the price at the mills across the line, we regulate the duty here, the Government regulates who can buy and who cannot, so I don't see that it is going to cause much commotion to go the rest of the distance. [illegible] effective in Canada."

Jobbers report a good demand in war lines, and mill deliveries for these purposes are fair. Transportation facilities are good at present.

### Scrap Metals

Large quantities of non-ferrous metals are being accumulated in the second-hand metal yards, for the good reason that there seems to be a rather limited demand for these at this time. On the other hand the yards are for the most part bare of all lines that are being called for by the furnaces working on war contracts. Brass, copper, zinc, lead, etc., are easily secured by traders, but the making of corresponding sales is not done so readily. Prices remain the same as last week.

It should be remembered in this connection that prices quoted in CANADIAN MACHINERY for scrap metals are the prices that would be offered to machine shops for the material they have for sale. They are not the prices at which the dealers here are offering to resell.

### Machine Tools

Several indications have come to our notice in the past few days that would seem to indicate that business interests consider that war orders are on a firm basis for some time to come. The latest of these is that a well known manufacturing house is working at present on a war purpose tool and is turning out twenty-five of them before a sale is made. The idea is that it is annoying to manufacturers to have to get their war plants on the piecemeal basis. It is also contended that deliveries guaranteed by some of the makers will be weeks late on account of the shortage of machine shop capacity to handle the business. This particular manufacturer believes that by placing himself in the position of being able to go to the manufacturer with a pressing war order and guarantee immediate delivery of a good line-up of machine tools, he can book business in a satisfactory manner. Is it likely that a batch of 25 machines would be run through without a sale or a contract if the maker was in doubt about the duration of the business? An advance has been recorded in the selling price of some lathes recently, due no doubt to the great demand for them. As a matter of fact it is hard to imagine that lists are adhered to in these times as closely as when industry is normal.

The demand for supplies is brisk, in carbon and high speed lines, war orders being continually on hand for the standard sizes of cutters, drills, etc., used in the machining of shells. Prices remain stationary.

# IRON TRADE REVIEW HINTS AT SOME CONTROL BEING TAKEN AT OTTAWA

*The Iron Trade Review* says: Tremendous new requirements for war steel not hitherto disclosed apparently underlie the Government's anxiety to command the full output of the mills and furnaces. A great ordnance program in which the Steel Corporation finally has agreed to take the leading part is significant of other enterprises of corresponding magnitude which now are being matured. Construction plans unparalleled in their size and requirements are taking form. A Government fabricating plant is reported to be among the possibilities. Producers quickly have adjusted themselves to the view that at least six months of full operations exclusively on Government business will be necessary. Despite all that is being said, however, as to the insufficiency of steel supply for Government requirements, the authoritative opinion of the industry is that not only will there be enough for war purposes, but in time some will be left over for commercial use.

The needs of the Allied Governments are surprisingly large. In shell bars, 750,000 tons each, it is stated, will be needed at an early date for England, France and Italy. The British continue to call for an unexpectedly large tonnage of plates, shell steel, rails, etc. Much of this is to replace the steel borrowed by General Pershing. The British wants are interesting in the light of the 1917 statistics just announced which show a steel production of approximately 10,000,000 tons, a higher record figure, and approximately 2,300,000 tons greater than before the war. Present production is considerably greater.

In Canada the question of commandeering the entire output of the works has been considered by the Government.

The mobilization of the pig industry on a war basis rapidly is taking place. Normal market movements in iron are suspended, but this has not deterred buyers from putting forth new inquiries.

The Government, concerned over the shortage in pig iron, continues to exert pressure on the railroads to furnish full supplies of cars to the coke regions.

# MILLIONS INVOLVED IN DEALS CLOSED

### Erection of Arsenal and Other Big Projects Are Well Under Way Now

Special to CANADIAN MACHINERY.

NEW YORK, May 21.—The production of crude steel during the first half of May has been at the rate of nearly 43,700,000 tons a year, while the blast furnaces have been producing pig iron at the rate of nearly 42,000,000 tons a year. The Steel Corporation subsidiaries have been producing at the rate of 95 per cent. to 96 per cent. of ingot capacity and independent steel companies are doing as well, their combined output being slightly more than that of the Corporation. If fuel supply is adequate and transportation facilities continue as at present, there will be a record-breaking run at all the plants, undoubtedly, up to Dec. 1st.

Notwithstanding the satisfactory headway being made by steel producers there is a lingering doubt at Washington, according to recent reports, that the Government requirements, including those of the Allies, may not be fully met if the Government does not assume fuller control of the industry. This opinion is strongly combated by the steel companies and there is a general sentiment against commandeering of the steel plants by the Government. It is considered entirely unnecessary and it is believed that such action would result disastrously for all concerned.

### Held a Conference

Executives representing large steel concerns were called to Washington yesterday to consult with the chairman of the War Industries Board to determine the most effective way to control and distribute the steel output. Many phases of the situation, including coal production, the transportation situation, and the possible curtailment of the less essential industries that consume steel, are understood to have been considered. A committee was appointed, including three members of the War Industries Board and five or six representatives of the steel manufacturers, to consider the various questions brought up at the meeting, a report to be made at a subsequent conference.

It is estimated that the construction of the Government arsenal to be built on Neville Island in the Pittsburg district, will require about 100,000 tons of steel, all of which of course will be furnished by the United States Steel Corporation subsidiaries. The equipment of the great plant will require the expenditure of about $40,000,000 and about one-third or one-fourth of this amount will be needed for machine tools. At a meeting of the National Tool Builders'

Association, held at Atlantic City this week, it was declared by an officer representing the Ordnance Bureau of the War Department that the Government will purchase about $10,000,000 worth of heavy machine tools and $5,000,000 worth of smaller tools for the manufacture of guns and projectiles. J. B. Doan, president of the association, brought out the fact, which has been emphasized in recent letters to CANADIAN MACHINERY many times, that there is a scarcity of large size machine tools such are required by the Government, and he pointed out that it is essential to take early steps to increase the production of such machinery that the tools may be available when the Government arsenals are ready for installations. The nation's aircraft program, he declared, collapsed because those directing the work failed to allow sufficient time for making patterns and templates of the special tools required for intricate work before beginning the manufacture of airships.

Gunmakers, shipyards and railroads, as well as manufacturers of agricultural implements, are now actively buying machinery of various kinds. The Wm. Cramp & Sons Ship & Engine Building Co. has come into the market with an inquiry for 18 cranes, the largest of its kind for several months. Four other shipbuilders are buying shop equipment. Makers of tractors are taking bids on $2,000,000 worth of tools.

## BIG MONEY NOW MAY MEAN A CUT

### Government Said To Be Watching Money Made By The United States Steel Industries

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., May 21.—The American Iron and Steel Institute's monthly report of steel ingot production indicates that in April production was at the rate of about 42,650,000 tons per annum. This is the best rate since last November and is about one per cent. above the average rate in 1917. The gain over March, however, is only 1.7 per cent. The increased production of pig iron, however, indicates that the rate of ingot production at present is between 44,000,000 and 45,000,000 tons, ingot production naturally lagging somewhat behind pig iron when there is a change in the rate. While ingot capacity is between 47,000,000 and 50,000,000 tons, the present rate is considered so satisfactory—it being generally felt that in these trying times operation absolutely at capacity can hardly be expected—that the chief concern of the industry now is to maintain the rate of operation rather than increase it. Soon the really hot weather will come, and in the past production has always decreased 10 to 20 per cent. in July and August. Mill managers are endeavoring to devise means that will avoid the usual curtailment. Consideration is also being given to the problem of next winter, to avoid as far as possible a recurrence of the difficulties of last winter.

#### The New Government Arsenal

Announcement has been made of the site of the arsenal, the building of which has been planned for some time past, through a partnership between the Government and the United States Steel Corporation. The site is Neville Island, an alluvial deposit in the Ohio river just below Pittsburgh. The island is well above high water mark, about five miles long and containing some 1,500 acres, with its upper end five miles below the city of Pittsburgh. The site is considered ideal, from the character of the land and its shipping facilities. At its head stands one blast furnace of some 550 tons capacity per day. This furnace was built by the American Steel & Wire Company just before the formation of the Steel Corporation, and under an announced plan whereby the wire company would build a very large steel plant on the island, concentrating all its Pittsburgh district operations at that point. Whether the plant really would have been built if the Steel Corporation had not been formed it has never been possible to decide. The blast furnace is now owned by the Carnegie Steel Company, and being a detached stack has been operated only in times of exceptionally heavy pig iron requirements. Details as to construction are lacking, but rumor has it one or two additional blast furnaces will be built. Then there will be built an open-hearthed steel plant, designed to cast such ingots as will be required for the large guns to be built, up to 16-inch. The blast furnaces and steel plant will be built and owned by the Steel Corporation. The gun and projectile plant will be built by the Steel Corporation and operated by it, but the funds will be supplied entirely by the Government. The Corporation donates its expert service, selecting from all its ranks the men best fitted for superintending the erection and operation of the plant. The Steel Corporation entered into the arrangement at the earnest solicitation of the Government and not only will make no profit but will donate a large amount of engineering and other skill.

About April 1 the representatives of

## COAL MINING AT PRESENT IS REALLY A DEPARTMENT OF OUR WAR SERVICE

Special to CANADIAN MACHINERY.

SYDNEY, May 21.—The extensive programme of reconstruction and new extensions which have been in progress at the plant of the Dominion Iron & Steel Company in Sydney is approaching completion. The reconstructed No. 1 blast furnace is ready for the heating-up process preparatory to being put into full blast, but it is not expected that the furnace will be in actual operation until a sufficient supply of coke is available. The new coke ovens are also approaching completion. It is expected that one battery will be in operation some time in July, and that the other battery will be commencing to make coke some time in September. The completion of these new ovens will make it possible to count upon a steady and full supply of coke, which the existing ovens are inadequate to supply.

The site of the new plate mill has been staked out, and work on the excavations and foundations will commence immediately. It is said that the mill will require a site of 1,140 feet in length. Details of the mill itself are not as yet available.

The Dominion Steel Company is now rolling rails to the order of the Government, and has temporarily at least discontinued rolling shell steel.

A Royal Commission appointed to look into questions affecting wages and labor at the steel plants in Nova Scotia is now in session at Sydney. The whole of the 14th, 15th and 16th of May were consumed in hearing the representations of the men's representatives and the company's case. The men are laying stress on the necessity to increase the rates of the lower paid workmen. There is really very little justification for a request for an increase to the higher paid men, who are earning very good wages. During the period from 1st January, 1916, to date, the Dominion Steel Company has granted wage increase to its workmen on the steel plant aggregating 56½ per cent. to all men, and to ordinary unskilled laborers 71 per cent.

The drafts now being made under the Military Service Act are expected to seriously reduce the available working forces both at the steel plant and at the collieries. The effect will be worst at the collieries, first because the collieries have already given an unusually high percentage of men to the army, and secondly, because the coal output is the basis of all the subsequent manufacturing processes. No one is inclined to dispute the wisdom of the Government in calling for reinforcements, nor dare anyone criticise the action of the Government in preferring reinforcements to production, but coal is a raw material of such primal importance that it must be looked upon differently from any other raw material, not excepting foodstuffs. If the transportation activities of our war effort are restricted everything else is restricted, even reinforcements. Probably the most important feature of the adherence of the United States to our cause is that the United States possesses large and excellent coalfields. The rapid conveyance of Americans to the French battle-front is a matter of ships, certainly, but ships cannot proceed to sea without coal. Coalmining to-day is not a civil industry, but is a department of our military organization.

the Government began to insist upon [illegible] war [illegible] of [illegible] plans and [illegible] of [illegible] to be [illegible]. The [illegible] had been [illegible] [illegible], as well as [illegible] Government representatives claimed that much [illegible] culminated in the meeting in New York April 27 at which the steel industry [illegible] all the steel [illegible] could be applicable to the various war uses. This was simply in deference to the [illegible] War Industries Board, as represented by J. Leonard Replogle, Director of Steel Supplies, and without prejudice to such estimates as the steel makers might make as to what tonnage really was going to be required, or how long it would take for the intensive program of shipping steel to stock the war activities fully and result in the Government desiring a curtailment in the rate of shipping.

The steel industry was not satisfied [illegible] of the information that had been gathered as to how much steel would be required, and presumably the War Industries Board was not satisfied either. One difficulty has been that the programs dealt very largely in total tonnages and very little in matters of time. A given batch of ship contracts, or of shell orders, for instance, would be made up involving a precise tonnage of steel, but not a precise time during which the deliveries would have to be made. The total tonnage would be known, but not the monthly rate at which the steel should be shipped. Probably upon the initiative of the steelmakers, a conference was held in Washington last week between representatives of the steel industry and of the War Industries Board, at which a joint committee was appointed to study in detail the tonnages and rates of delivery that will be required. This committee is now at work. What the Government desires, in the way of ships, shells, guns, etc., is relatively well known, but what is to be determined is the rates at which the various activities, consuming steel for the production of these things, will be able to operate and receive and consume the steel. When this investigation has been completed there will undoubtedly be a much clearer view of how much steel is going to be left, in future, for commercial purposes. At the present time the mills are simply shipping the maximum they can turn out for war activities, and the steel that is not of a character suiting it to war-work is being distributed to commercial consumers, as largely as possible in proportion to the importance of the customer as to his aiding indirectly in the prosecution of [illegible].

### The Market

In the circumstances, there is practically no steel market, for what little steel is available naturally goes to the filling of commercial orders long on the books. It is no novel situation, however. [illegible] pre-vailed early in the year, when production was so greatly curtailed.

Nothing definite is said as to prices that may rule on the million tons of steel products that will be required to fill the orders for 100,000 freight cars, recently let by the Railroad Administration on a cost plus 5 per cent. basis. It is known, however, that the Railroad Administration has demanded concessions from the set prices, and the matter may have to be referred to the President. Discussion on this subject may open up the matter of what prices are to rule after June 30 as the set maxima, the existing prices having been, towards the end of March, continued for the second quarter of the year. The steel mills are making large profits. Even in the first quarter of the year, when conditions were so unfavorable, there were relatively large profits and conditions are now much better. In the circumstances, some members of the trade think it far from improbable that the Government will seek lower steel prices for the future, or the excess profits tax will be increased by Congress. The fact that the subject is not openly discussed does not indicate that it is not a very live topic.

## SHELL OUTPUT IN CANADA IS LARGE

**Official Figures Give Some of the Records of Production Here**

From recent information given out by the Imperial Munitions Board it is found that Canada's contribution during the last year had been very striking. Fifteen per cent. of the total expenditure of the Ministry of Munitions in the last six months of the year was incurred in that country. She has manufactured nearly every type of shell from the 18-pr. to the 9.2.

### 55 Per Cent. of 18-Pounders

In the case of the 18-pr. no less than 55 per cent. of the output of shrapnel shells in the last six months came from Canada, and most of these were complete rounds of ammunition which went direct to France. Canada also contributed 42 per cent. of the total 4.5-inch shells, 27 per cent. of the 6-inch, and 20 per cent. of the 8-inch, and 16 per cent. of the 9.2-inch. In addition, Canada has supplied shell forgings, ammunition components, propellants, acetone, T.N.T., aluminum, nickel, nickel matte, airplane parts, agricultural machinery and timber, besides quantities of railway materials, including no less than 450 miles of rails torn up from Canadian railways, which were shipped direct to France.

During the present year the call has been largely for 6-inch h.e. shells, and Canadian plants are responding with an output which represents over 40 per cent. of the British programme for this sized shell.

**Montreal.**—The Grand Trunk is receiving this month delivery from the American Locomotive Company of ten Mikado type locomotives for use in freight service. These powerful engines can handle a freight train of six thousand tons. Ten locomotives of similar type have recently been received from the Canadian Locomotive Company at Kingston.

## WINNIPEG NOT IN FAVOR OF BEING TIED UP TO WESTERN COAL MINERS

THE *Winnipeg Free Press* objects seriously to the move to have Alberta mines supply the West with coal, to the exclusion of the Pennsylvania article. The *Free Press* says in part:

Worthy of admiration, in a way, is the "nerve" of the Alberta coal operators in hastening to advise the authorities at Ottawa that there is no need to worry about the fuel supply of Canada, west of the Great Lakes, since they will guarantee a full supply from their mines. They are not lacking in confidence or ambition; but it would be literally a cold day for the people of this city if the Fuel Controller were to listen to their siren song.

Alberta is the place where the alien enemies who condescend to operate our coal mines strike every other week for higher pay. The Government has a special representative out there, who is kept galloping around from coal field to coal field, adjusting difficulties which spring up overnight, and boosting wages. Last year, all the miners in the district were out for weeks in defiance of the orders of the officials of the international organization to which they belong; and during the month of March this year most of the coal mines in the Drumheller area were out of business because of labor troubles.

According to very reliable reports, 60 per cent. of the miners in this district are registered alien enemies. They have got their wages up to the point where they can earn $15 a day. Not having any use for so much money, most of them only work part of the time, thus restricting output in an essential of life.

The proposal to put a city of 200,000 people at the mercy of such a combination is amazing. The first thing that would happen, if anthracite coal were barred from Western Canada, would be another wholesale strike, which would be ended by the obliging representatives of the Government putting the wages of the miners up to perhaps $25 a day, on the plea that since coal must be had the demands of the alien enemies must be conceded. Judged by heat values, the coal for Winnipeg houses would cost probably twice what it does under existing conditions—constituting a killing burden upon the poorer element of the population

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

## THE FARM DRIVE IN BRITAIN

Science has done the impossible in this war. When the gasoline supply became so limited that all available stocks were taken over for the use of the army, then science provided gas as a propelling power. The photo shows a gas driven tractor in Britain's drive for production. The gas is contained in a huge envelope on top of the tractor and soldiers on leave have been trained to use these tractors and ploughs.

## RECORD ONTARIO MINERAL OUTPUT

THE mineral production of Ontario during 1917 marks high-water point in the record of the mineral industry of the province. The total amounted to $71,060,942, an increase of $5,757,120 compared with 1916. A notable fact in connection with the returns for 1917 is that while metallic mineral production showed an increase of but $1,840,000, made possible by a $3,500,000 jump in the value of the nickel output, which more than balanced a reduction in gold and copper matte, there was a jump of nearly $4,000,000 in the value of non-metallic minerals. The value of Ontario's arsenic production more than trebled, chiefly owing to the increased value of arsenic in the world's markets. The production of iron pyrites was doubled and the value of the output trebled.

### Details of Production

In the following table, issued subject [illegible] output of Ontario for 1917. Comparative figures for 1916 are included:

| | 1917 | |
|---|---|---|
| [illegible] | [illegible] | [illegible] |
| [illegible] | [illegible] | [illegible] |
| [illegible] | [illegible] | 119,107 |
| [illegible] | [illegible] | 7,842,880 |
| [illegible] | [illegible] | 6,943,500 |
| [illegible] | [illegible] | 488,690 |
| [illegible] | [illegible] | 1,036,699 |
| Cobalt oxide | 288,611 | 586,290 |
| Cobalt oxide | 458,714 | 533,489 |
| Nickel oxide | 19,438 | 6,533 |
| Nickel (metallic) | 17,847 | 91,923 |
| Other nickel and cobalt compound | 60,956 | 42,026 |
| Molybdenite, concentrates | 26,393 | 108,501 |
| Lead | 70,863 | 172,601 |
| Metallic total | $55,002,918 | $56,845,788 |
| Non-metallic | | |
| Arsenic, white, grey and other forms | 200,102 | 608,184 |
| Asbestos | 100 | 2,150 |
| Brick, fancy and pressed | 318,942 | 462,357 |
| Brick, common | 509,559 | 769,540 |
| Tile drain | 275,471 | 468,886 |
| Do., hollow blocks | 176,953 | 301,528 |
| Cement, Portland | 2,242,433 | 2,934,271 |
| Corundum | 8,763 | 31,213 |
| Feldspar | 42,159 | 27,629 |
| Fluorspar | 10,146 | 64,673 |
| Graphite, refined | 249,586 | 210,018 |
| Gypsum, crushed, ground and calcined | 116,206 | 128,828 |
| Iron pyrites | 471,807 | 1,066,575 |
| Lime | 265,356 | 269,461 |
| Mica | 55,407 | 79,516 |
| Natural gas | 2,401,499 | 3,182,151 |
| Petroleum, crude | 387,846 | 475,000 |
| Pottery | 87,025 | 91,501 |
| Quartz | 223,514 | 382,993 |
| Salt | 700,515 | 1,095,866 |
| Sand and gravel | 470,963 | 427,303 |
| Sewer pipe | 216,749 | 205,810 |
| Stone, building, trap, granite | 755,313 | 749,160 |
| Talc, crude and ground | 111,489 | 179,554 |
| Total, non-metallic | $10,300,904 | $14,218,269 |
| Add metallic | 55,002,918 | 56,845,788 |
| Grand total | $65,303,822 | $71,060,942 |

The total yield of gold in Ontario to the end of 1917 amounted to over $42,000,000. Discoveries of gold continued to be made in various parts of Northern Ontario.

Since the discovery of silver at Cobalt in 1903, shipments of silver have amounted to 274,000,000 ounces, valued at $151,960,000.

### Huge Nickel Ore Reserves

The output of nickel copper matte in 1917 was 78,897 tons. During the year 1,453,000 tons of ore were smelted at the Copper Cliff and Coniston smelters. The known reserves of nickel ore were estimated a year ago at 70,000,000 tons, but it is believed that the results of diamond drilling have added nearly 100 per cent. to the quantity.

The value of the output of non-metallic products for 1917 was greater than in any preceding year except 1913, the amount being $14,218,000 in 1917, as against $15,724,000 in 1913.

Four gold mining companies paid out in dividends $1,699,000 and thirteen silver mining companies nearly $6,000,000. The total dividend distribution by silver and gold companies combined up to the end of 1917 was over $82,000,000.

# INDUSTRIAL NEWS

## NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

## MUNICIPAL

Napanee, Lennox and Addington Counties are considering building a concrete and steel bridge. The engineer is T. V. Anderson of this town.

Port Dover.—Tenders will be called [illegible] for the erection of [illegible], costing between $15,000 and $20,000, for the Town Council.

**Fergus, Ont.**—The Town Council are considering the installation of a fire [illegible] with the box system and the electric siren were considered. The matter was finally left in the hands of [illegible].

**Goderich.**—The Dominion Road Machinery Co. of Goderich shipped a complete rock crushing plant to Haliburton for the Township of Dysart. This makes the fourth crushing plant shipped within the last two weeks. They also have shipped out two carloads of graders and several more will be shipped before the end of this week. They are being shipped to Winnipeg, Calgary, Quebec, and Sherbrooke.

**Fort William.**—At a meeting of the finance committee at Fort William, the [illegible] was recommended to be [illegible] to the Fort William board of trade. It was also recommended to accede to the request of the Canadian Car and Foundry Company to have the company's bond for $250,000 cancelled, in consideration of their having carried out more than the required expenditure upon the plant here. The solicitor will be asked to take the matter up and see that all legal requirements are complied with.

**Hamilton.**—*The Times* says: City Engineer E. R. Gray informed the civic fathers to-day that new tenders will have to be advertised for in connection with the two boilers for the steam equipment at the Beach pumping station, as he had been advised by the Babcock, Wilson Company, of Montreal, who are Canadian agents for the British boiler manufacturer who was originally given the contract, that the Imperial Munitions Board would not permit the boilers to come to Canada, it being inferred that they are needed for marine purposes Mr. Gray said this unforeseen contingency would not delay matters greatly at the Beach pumping station, providing new contracts were let, as other suitable boilers could be secured from Canadian manufacturers.

## PERSONAL

**J. W. Shackleton** has received the appointment of city engineer of Chatham Ont.

**Stacey Opdyke** has been appointed as manager of the water sterilization department of the Northern Electric Co., Montreal.

**W. R. Daye**, who has been advertising representative of the T. McAvity & Sons, St. John, N.B., has enlisted. His predecessor in the position, Mr. Erb, is also in the service.

**J. A. St. Germain**, for the past twelve years secretary-treasurer of the Canada Stove and Foundry Company, of St. Laurent, P.Q., has severed his connection with that firm, and has taken over the business of the Imperial Supply Co., 104 Delorimier Avenue, Montreal, as wholesale jobbers and general manufacturers' agent.

**J. N. Robinson**, Toronto and Hamilton representative of CANADIAN MACHINERY, has received word of the death in action of his brother, Flight-Lieut. W. Hartley Robinson, of the Royal Air Force. He was serving on the Italian front. Prior to enlisting he was a reporter on the Toronto "Star," and latterly editor of the "Canadian Motorist."

**S. E. Chadsey**, assistant to the general superintendent of the Massey-Harris Co.'s plant at Toronto, has been made general manager of the agricultural implement plant at Brantford, Ont., to succeed Franklin Grobb, who has retired because of ill-health. The latter continues his connection with the company in an advisory capacity only. R. D. Johnson has retired as superintendent of the Brantford factory, and is succeeded by John W. Dunn.

## TRADE GOSSIP

**Change Office Location.**—H. W. Johns-Manville Co., New York, give notice that their Houston office will be located, on and after July 1, at 424-426 Washington Ave., Texas.

**Big Contract.**—Official announcement was made of the acceptance of a contract by the Motor Trucks, Ltd., of Brantford, for the manufacture of war material for the United States Government. The contract involves an expenditure of approximately $7,000,000, and the terms call for completion by January 1, 1920.

**Goes to New Hamburg.**—The North-Light Motor Co. of Toronto, with offices in the Wesley Building, have recently taken over the large two-storey factory at New Hamburg, formerly occupied by the Silversmith Mfg. Co., which is 40 feet by 140 feet long, for the purpose of manufacturing a high-grade, 4-cycle, high speed gasoline motor, for marine, automobiles, trucks, tractors, stationary engines, etc.

**To Build Briquette Plant.**—It is announced that the federal government has sanctioned the plan whereby a plant for the manufacture of briquettes from lignite coal will be established in the Estevan district. The federal government will provide $200,000, and Manitoba and Saskatchewan each $100,000. This plant will be erected as soon as possible, and may prove a factor in the solution of the pressing fuel problem.

**Manufacturers Protest.**—At a general meeting held in the Kerby House at Brantford of the manufacturers of the Counties of Brant, Elgin, Oxford, Norfolk, Haldimand, Welland, Lincoln and Wentworth, it was decided to send a delegation to Toronto to arrange for a meeting in regard to the order for the curtailment of the gas supply of manufacturers in this district. There was a representative attendance of about forty manufacturers present, many of whom were entirely dependent upon gas to operate their respective plants.

**New Equipment.**—The Otis Fensom Elevator Co. have purchased a 50 h.p. motor-driven De Laval 3-in. three stage centrifugal pump for use in connection with a hydraulic elevator, which they will install in the Bell Telephone Building. The Hydro-Electric Power Commission of Ontario have purchased six De Laval single and multi-stage pumps for the Ontario Power Company. These range in sizes from 100 to 150 h.p., and all will be motor driven. Sales were made by the Turbine Equipment Co., Ltd., Toronto.

**Coal Mixing Plant.**—A coal mixing plant is to be installed by the Grand Trunk Pacific Railway at Edson, and contracts for the construction work are now being awarded. The purpose of the works will be to combine three different grades of Alberta coal into a standard fuel, which will be used on all locomotives of the system between Winnipeg and Prince George ,and the consumption of home mined coal will thereby be increased to the extent of 200,000 tons a year. The plant will be in operation about the 1st of August, and employment will be given to some fifty men.

**Ten New Companies.**—Incorporation has been granted to the following joint stock companies: Swan Lake Farm, Limited, Toronto, capital $500,000; Fairfax Forgings, Limited, Montreal, capital $1,500,000; Oppenheimer Casing Com-

*If any advertisement interests you, tear it out and [illegible]*

[illegible] Toronto, capital [illegible] Chemical Company of Canada, Limited, Toronto, capital $50,000; Saxon Motors Corporation of Canada, Limited, Windsor, capital [illegible]; Alfred & Company, Limited, Montreal, capital $1,000,000; Frank [illegible] & Company of Canada, Limited, Vancouver, capital $50,000; Petroleum & Gas Products, Limited, Toronto, capital $1,000,000; Dillon Crucible Alloys, Limited, Welland, capital $110,000; Canadian Buttons, Limited, Montreal, capital $25,000.

**Big Nickel Plant.**—The contract for the construction of a nickel and copper refining plant at Deschenes, Que., for the British-American Nickel Corporation [illegible] job before the snow falls. The plant will be constructed entirely of concrete. The buildings and machinery will cost over a million dollars. It is understood that both British and Norwegian interests are back of the scheme. The production of refined metal from the completed plant will be very large and on a scale hitherto unknown in Canada. The company operating the plant has mines in the Sudbury district, where the smelters are located, so that the business between there and Deschenes will mean considerable of a melon to the railroads in freight charges on the ore.

## TENDERS

**Ottawa.**—Sealed tenders will be received until 4 p.m., on Monday, May 27, 1918, for the construction of a Dominion Government Office Building, O'Connor St., Ottawa, Ont.

**Ottawa.**—Tenders, marked "Tender for rebuilding lower entrance pier, Lock No. 23," will be received until 12 o'clock noon on Wednesday, June 5, 1918. J. W. Pugsley, secretary. Department of Railways and Canals, Ottawa.

**Amherstburg.**—Plans and specifications can be seen at the office of A. C. Cailleux, Amherstburg, who will receive tenders until 4 p.m., June 15, for the erection of two steel bridges, costing $13 000, over the Canard River, for the Township Council.

**Ottawa.**—Tenders will be received up to noon, Friday, May 31, 1918, for the construction and installation of two coal discharging bridges at Halifax, N.S. Full particulars may be obtained on application to the undersigned or to the Admiral Superintendent, H.M.C. Dockyard, Halifax, N.S. G. J. Desbarats, Deputy Minister of the Naval Service, Ottawa, May 10, 1918.

**Winnipeg.**—Sealed tenders will be received up to 10 a.m. on Friday, May 31st, 1918, for the supply of one combination hose wagon and pumper for the Fire Department of Winnipeg. Specification and form of tender, together with conditions governing tenders as prescribed by by-law, may be obtained at the office of the Chief of the Fire Department, Central Fire Station, Winnipeg. M. Peterson, Secretary, Board of Control Office, Winnipeg, May 10, 1918.

## MARINE

**Toronto.**—The Canada Steamship Lines Ltd. announce the opening of navigation across the lake to Niagara-on-the-Lake, Lewiston and Queenston. The first trips were made on Saturday, the 18th.

**Port Arthur.**—The latest move in the strike situation is the bringing in of some 150 women as strike-breakers. There is some difference concerning the advisability of such a move, some of the citizens offering criticism to the employing of women for such heavy work.

**Thos. Robb and James N. Bales,** of the Royal Commission, appointed to investigate into the pilotage conditions at the various harbors of the Dominion, are leaving for the Pacific Coast about the 11th of the month to complete their work at the different ports in British Columbia. They expect to be away for about a month.

**Ottawa.**—The Cabinet Council, on recommendation of Hon. F. B. Carvell, authorized the transfer to the St. John Drydock and Shipbuilding Company of the contract originally given to the Norton Griffiths Co. for the St. John harbor works. The new company, composed of prominent Canadian shipowners and builders, takes over the contract on the same terms as those granted to the Norton Griffiths Company when Hon. Dr. Pugsley was Minister of Public Works.

**Victoria, B.C.**—Only on the basis of a minimum rate of $6.60 per day for basic trades and a 44-hour week, with the proviso that whatever advance may be granted in the shipyards of the Pacific Coast of the United States by the reason of the increased cost of living be conceded the shipyard workers of British Columbia, will the shipyard and affiliated trades be prepared to sign up a permanent working agreement for the duration of the war, declared labor leaders.

**Vancouver.**—Fire in the J. Coughlin & Sons' shipyard on False Creek did damage on May 15 to the extent of between $1.500.000 and $2.000.000. A fireman was killed. The steel steamer War Chariot, about two-thirds completed, was engulfed in the flames. The ways, which are built on piles, fell through and the hull twisted by the heat, is now half-submerged in the water beneath. The hull of the steamer War Charger on No. 3 ways still stands, but the plates are badly buckled by the heat.

**Toronto.**—The Trojan, a 4,200-ton freighter, built at the foot of Bathurst street by the Thor Ironworks Company and Dominion Shipbuilding Company, for the Great Lakes Transportation Company of Midland, was successfully launched, and was christened by Mrs. Johannas Linvig, wife of the owner. The Trojan is a sister ship to the Angouleme, with 43.6 beam and 28 2 moulded depth, and is valued at $750.000. She was sold while on the stocks to Mr. Linvig for ocean service. Her first trip will be to Kragero, Norway.

**Cleveland.**—Ore is moving at a much faster clip than a year ago. Forty-four ore carriers were loaded at all ports in one day, and thirty-one vessels were waiting and loading the following morning. Boats are getting around pretty fast, as many of the big carriers are going up light on account of scarcity of coal. The coal movement is slipping, if anything, and boats are more plentiful than cargoes all along the line. Many of the regular traders are going up light, and small carriers, which are usually in big demand, are unable to get loads.

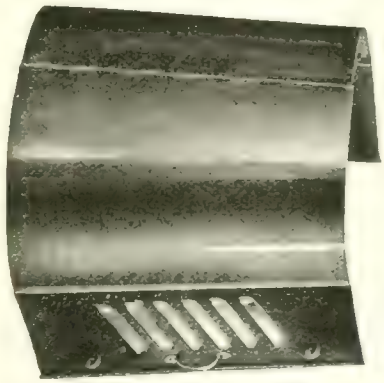
**Washington.**—The proposal to use electric welding in place of rivets in securing the plating of a ship is an attractive proposition if it can be done successfully. Tests which were recently made in the presence of the representatives of the Shipping Board have been so satisfactory that one of the engineers of the Emergency Fleet Corporation has been sent to Newark, where the system is to be tried on a 9,500-ton ship which is about to be built by the Federal Ship Building Corporation of Newark, N. J. According to the despatch, a low voltage is used and the current is applied to the metal through the ends of large forceps which press the sheets firmly together after the metal has become sufficiently heated to effect a weld.

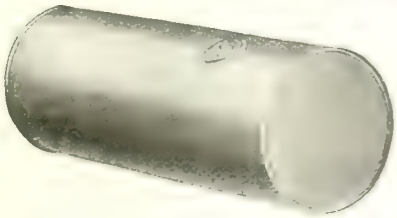
**Not an American Concern.**—A rather erroneous report has found its way into print in connection with a factory that is being erected in the east end of Toronto to handle large war business. It was reported that "an American company represented in Toronto by the Holden-Morgan Company" was undertaking the work. The Holden-Morgan Co. themselves are behind the enterprise, and they have no connection whatever with any American concern in this business. This company has recently taken on large war orders, and the new plant is being erected for the handling of this business. The main building will be 100 x 300 feet, and in addition to this there will be heat-treating plants, shipping houses, etc. Two sidings are being placed on the property, one for the purpose of receiving and the other to ship out goods. Some 3¾ acres of land are being used in the building of the new plant, and it is expected that it will be ready for operation within the next two months.

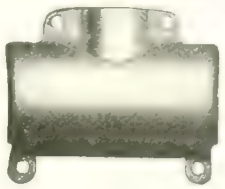
## CATALOGUES

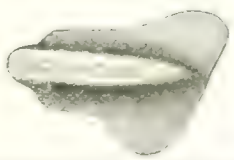
"The Proper Care of Belts," is the title of a booklet gotten out by the Joseph Dixon Crucible Company. We suggest that engineers obtain a copy for their files. As long as the original condition of life and pliability of a belt is preserved it is worth its cost price. To neglect belts will result in a two-fold loss; a waste of power due to the inefficiency of the belts and increased cost due to frequent belt renewals. Just now as never before it is essential that belting be given careful attention. The booklet contains helpful suggestions for getting maximum results from belts and in addition has several pages devoted to useful information of a general character.

# SHEET METAL STAMPINGS









OUR plant is equipped with batteries of heavy presses and hammers to take care of every class of stamped and deep drawn metal work. But that is not all. During the many years we have been developing this department, we have gathered together a staff of mechanics who thoroughly understand every phase of the work.

We have every facility that assures accuracy, quality and prompt service. Your inquiry is solicited. Put your stamping problem up to us.

## THE PEDLAR PEOPLE LIMITED

Manufacturers of

PEDLAR'S "PERFECT" SHEET-METAL PRODUCTS

OSHAWA ONTARIO

IT is a national necessity at present for Canada to improve her trade balance with the United States.

Manufacturers who are buying forgings or drawn or stamped metal parts outside of Canada, can do something towards helping this trade balance, by calling upon us for these goods.

We are equipped to make practically anything in a steel forging or steel stamping. Our capacity is so large that we can give prompt delivery; and our efficiency is such that we can quote you attractive prices for high class work.

**Dominion Forge & Stamping Co., Ltd.**
WALKERVILLE, ONTARIO
Toronto Office: 510 Lumsden Building

Chilled Iron
# NOSING DIES
Have Long Life

Since last June we have been using the same Die in our Nosing Press. In that time it has nosed over 50,000 shells in a manner satisfactory both to our own Inspectors and the Government Inspectors.

Some of our customers are getting nearly as good results, nosing anywhere from 10,000 to 25,000 shells with one die.

Others are not getting as good results, and we have reason to believe they discard the die too soon.

We find these Chilled Iron Dies will check on the wearing surface after being in use only a short time. **Do not discard them then.** These checks in no way impair the efficiency of the Die. They are only checks, not cracks, and the Die may be used for thousands of shells after these checks develop.

**PRODUCTION OF MINERALS IN 1917**

IN a preliminary report on mineral production in Canada during 1917 John McLeish, B.A., chief of the division of mineral resources and statistics, points out that it is customary to express the total mineral production and to make comparison of production in different years in terms of dollars or total values.

On this basis of record and comparison the total value of the metal and mineral production in 1917, as shown in this preliminary report, was $192,982,837. Compared with a production in 1916 valued at $177,201,534, an increase of $15,781,303, or 8.9 per cent., is shown, while compared with a production in 1915, valued at $137,109,171, there is shown an increase of $55,873,666, or 40.8 per cent.

It must not be inferred, however, that because such a large increase is shown in the value of our mineral production, that our mines and quarries have actually increased their tonnage output at the same average rate. In fact, an examination of the record will show that the quantities of many important products were considerably less in 1917 than in 1916, and over two-thirds of the increase in value is to be attributed to coal, gypsum and cement, in which the quantities marketed were less than in the previous year.

The interrelation of industry is shown by the effect of a diminished coal and coke output on the metallurgical production, the falling off in production of copper and gold is in part attributable to this cause. Lead and silver also show much smaller output. As against these decreases there has been an important increase in the production of zinc, and increases also in the production of cobalt, molybdenite, and nickel.

In 1916 the metal production showed a very large increase over that of the previous year, but in 1917 the net result in value has been an increase of only $311,387, making a total value of $106,630,752.

The total value of the non-metallic production, including clay and quarry products in 1917, was $86,352,085, as compared with $70,882,169 in 1916, showing an average increase of $15,469,916, or 26 per cent. Practically every product, with the exception of the stone quarry output, shows an increased value of production; but in the case of coal, graphite, gypsum, and cement, the quantities actually marketed were less, notwithstanding the increased values.

In representing a total valuation of the mineral production as is here given, it should be explained that the production of the metals—copper, gold, lead, nickel, silver, and zinc, is given as far as possible on the basis of the quantities of metal recovered in smelters, and the total quantities in each case are valued at the average market price of the refined metal in a recognized market. There is thus included in some cases the values that have accrued in the smelting or refining of metals outside of Canada.

---

**Owen Sound.**—Sealed tenders will be received up to noon of the 10th day of June, 1918, for the purchase of the steamer "La Canadienne," now lying at Owen Sound, Ont. "La Canadienne" is a single screw steamer of iron construction, built in 1880. Her net registered tonnage is 227 and her displacement is 500; is 154 feet long, with a breadth of 23 feet and a maximum draft of 11 feet. Her maximum speed is approximately 8 knots. Her boilers are in good condition. She is fully equipped for commission, and carries a motor boat and four sail boats, with accommodation for 55 men. She may be seen and inspected at any time upon application to Mr. John Nesbitt, of Owen Sound. The ship will be sold as she lies.

Lanco Balata Belting

is now one of the most expensive belts on the market.

When the cost of raw materials increased the price of this belt to where it is to-day, we were a little afraid that it would result in a diminution of our sales. We have been very agreeably disappointed the sales have not dropped off.

There are cheaper belts on the market that will give as good service but not for so long. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the picks tightly together, is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that, as far as we know, has never been equalled by any other gum. The duck is of course stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions, except those of heat, it will give a length of service that makes its price worth while.

# Making New Locomotive Parts from Scrap Heap Material

By Paul H. Cain *

*Putting old parts into new, much as seems somewhat opposed to the Biblical injunction to put not the new wine in old bottles etc. Circumstances alter cases, however, and where there are no new bottles the old must be made to do. Hence the conservation effort described by the writer. Doubtless similar and equally as economical practices will be suggested in allied lines of engineering.*

OWING to the general abnormal conditions, incidental to war activities, prevailing throughout the country at the present time, the pronounced scarcity of material and labor has been forcibly brought to our attention so that we have had to adapt our available resources to meet the needs of the situation, hence the use of methods for greater conservation by reclamation of material that in normal times would be considered as useless scrap, and converting the same into product of serviceable character and at little expense.

The M. C. R. R. shops at St. Thomas, Ontario, have for a long time been studying and practising conservation in connection with operations where iron and steel enter into construction.

All broken and obsolete parts of locomotives and car equipment, consisting of brake beams, brake rods, levers, chains, bolts, nuts, pins, spring buckles, spring hangers, draw bars, arch bars, axle journals, frames, and any scrap which may accumulate around shops are utilized in this process. These parts are chopped or sheared into pieces not exceeding 12 inches in length, then piled on boards 12 inches by 12 inches, each pile weighing from two hundred to two hundred and fifty pounds. It is then charged into a furnace equipped with Economy combustion chamber and burners, as illustrated in Fig. 1, the capacity of the furnace being sufficient to accommodate twelve piles at one time. It is then heated to a welding heat and conveyed from the furnace to the steam hammer by means of a pair of grab tongs suspended from the crane. It is then forged into slabs 2½ x 14 x 30 inches.

Fig. 2 shows a pile in position on the hammer die ready for forging into slabs; to assist in welding these slabs a porter bar is used. Any number of these slabs are piled together according to size of forging desired and again welded into a billet, after which they are forged into their desired shape. In Fig. 3 is illus-

FIG. 1—PILE OF SCRAPS READY FOR CHARGING [illegible] FURNACES.

which is made from these slabs. In order to get a forging of this size where the overall length is upward of 6 feet it is necessary to pile four of the slabs together, using a porter bar. After the slabs have been heated the centre portion is forged into the oblong shape 5 inches by 3 inches; an extra heat is then taken on each end and the metal forged to the oval shape and the holes punched.

Sketches 5 and 6 show an inside frame patch and also a combination frame patch and driver brake shaft bracket, both of which are now being made from reclaimed scrap iron.

This method of utilizing scrap is very suitable to the construction of the cylinder equalizer illustrated in Fig. 7. This piece, which has a total length of nearly 8 feet, has an approximate weight of nine hundred and sixty pounds.

One of the most efficient tests we have found for this material is that of manufacturing it into locomotive links, as shown in Fig. 8. After carbonizing and heat treatment of the links made from this process the result has been highly satisfactory in every respect. The writer's experience in obtaining the best results in carbonizing these links has been as follows:—After baking in a carbonizing furnace for at least fourteen hours, the box is removed and allowed to cool. The decalescence of iron being about 1650 degrees F., while the decalescence of carbon steel is 1440 degrees F., therefore, in order to get a refined grain iron on the inside of the case, reheat the link to the decalescence of iron and

*[illegible] blacksmith, Motive Power [illegible] R R Shops, St. Thomas, Ont.

[illegible] BEING WELDED UNDER HAMMER

quench in water. In order to get the [illegible] to about 1440 degrees F. and quench, which gives you both the refined grain of the iron and also the steel.

Fig. 9 shows a "T" headed draw bar pin that is forged from this material. This system of reclamation is very adaptable to railroad shops, as it requires no additional or special equipment other than that which is already installed, and its adoption has proven a great saving in this particular plant, the most essential factor being the use of a good furnace and good combustion chambers.

## SMALL ELECTRIC FURNACES AND THEIR USES

My Mark Meredith.

Until quite recently the use of small electric furnaces was restricted to certain special operations in the laboratory. They were constructed of platinum foil wound on a porcelain tube, on the outer side of which an insulating cover was placed. On passing a current of sufficient strength through the foil, a temperature of 1400 deg. Centigrade or more could be obtained in the interior of the tube; and any desired temperature could be maintained below this limit by adjusting an external resistance.

The dimensions of the porcelain tube were commonly about 15 inches long by 1½ inches diameter (internal) and the arrangement proved of great service in [illegible] peratures. The high cost of platinum, together with the fact that careful control and oversight were necessary to protect the winding from fusing, prevented this form of furnace from being widely adopted, and it was seldom found in the workshop. The necessity of a furnace suitable for testing the effect of heat treatment on metals led to trials of nickel windings in the place of platinum, the only gain, however, being diminished cost, as the nickel was more liable to burn out than the platinum.

Both kinds suffered from the further defect that the porcelain tube frequently collapsed when the full current was switched on suddenly, and neither could be used to advantage unless in the hands of a skilled operator. These troubles have now been overcome, the introduction of fused silica and alundum tubes, together with the marketing of nickel-chromium (nichrom) wire and strip having resulted in the production of extremely useful furnaces, which possess none of the drawbacks mentioned, and which are being used in ever-increasing numbers in the workshop and the laboratory. The well-known property of fused silica, which may be thrust into a hot furnace or quenched in water from a white heat without cracking, renders it specially suitable for use in small electric furnaces. Alundum does not resist sudden temperature changes so well as silica, but is superior to porcelain in this respect, and seldom cracks when used in this connection. Moreover, alundum tubes are more regular in shape than those made of silica, and are less readily attacked by metallic oxides; they are, however, more expensive. Nickel-chromium alloys of suitable composition, may be safely heated to 1100 deg. Cent., without noticeable oxidation, and show only a small increase in resistance as the temperature rises, the co-efficient being 0.00016 per deg. Cent.

The limit at which a furnace wound with nichrom may be worked continuously is 1000 deg. Cent., which is 400 deg. less than the safe temperature attainable by the use of a platinum winding; but as a great number of important operations are conducted below 1000 deg. Cent., the smaller range does not detract from the utility of nichrom.

The small change in resistance with temperature is a valuable property in this connection, as a nichrom winding may be switched on to mains with impunity, a cold resistance of 8.6 ohms rising to 10 ohms at 1000 deg. Cent.; and hence, if the current were 10 amps at the higher temperature, it would only be 11.6 amps. when switched on at the cold winding. A platinum winding having a resistance of 10 ohms at 1000 deg. Cent., however, would fall to 2.4 ohms when cold, and if 10 amps. were taken from the mains when hot a current of over 40 amps. would flow through the coils when cold; and any part thinner than the rest would be liable to fusion. Hence for safety the current in a platinum furnace must be controlled by an external resistance, which is gradually cut out as the temperature rises—a process involving a waste of time, labor and current as compared with nichrom windings. A similar objection applies to nickel and all other metals of high temperature co-efficient. Further advantages of nichrom are cheapness and resistance to corrosion by metallic fumes or contact with hot silica or other refractory.

Considering the question of cost of running, a tube 15 inches long and 1 inch internal diameter suitably lagged may be maintained at 1000 deg. Cent.,

FIG. . LOCOMOTIVE FRAME MADE FROM SCRAPS.

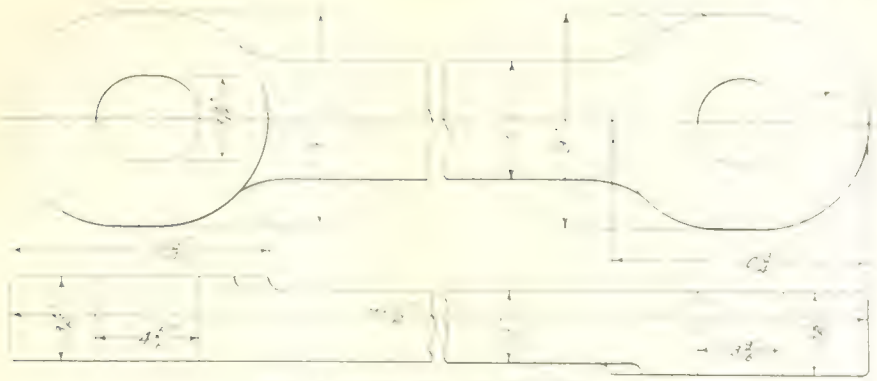

FIG. [illegible] TYPE K-50 DRAW BAR

by the expenditure of electricity at the rate of [illegible] kilowatt, or a cost of one cent per hour, when current at two cents per unit is obtainable. If the same tube were to be heated by gas the cost would be much greater, as in this case the products of combustion must escape at the temperature of the heated object, resulting in a considerable loss of heat. The superior economy of the electric furnace, however, disappears when the size is large enough to permit of internal gas heating. It is not possible to state definitely the maximum size to which an electrical furnace may be made economically, but the limit would probably be reached when the area of the heated furnace was about six feet square. The initial cost of the electric

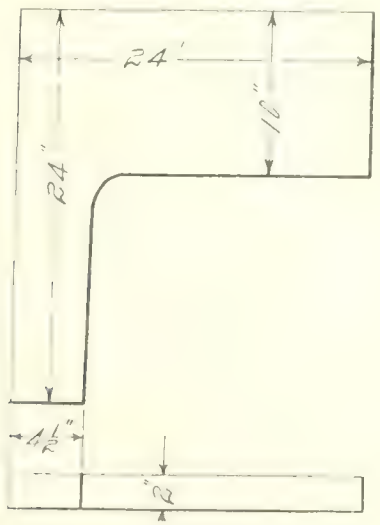

FIG. 5 INSIDE FRAME PATCH.

furnace does not differ greatly from that of a gas furnace of similar capacity, and the present popularity of the former is due to its convenience, cleanliness, and the ease with which temperatures may be exactly controlled by means of an external resistance.

A type of furnace is made with a silica or alundum tube wound with nichrom wire or ribbon and fitted at each end with a sheet of uralite. In order to prevent longitudinal movement, a second piece of uralite, provided with a hole equal in diameter to the inner part of the tube, is fastened to the first piece, and the structure is held together by four iron tie-rods, the two lower of which serve to connect the windings to terminals on the exterior. This heating element is placed in an iron case, lined with magnesia insulating bricks, and the airspace round the tube is then filled in with asbestos or powdered silica. Amongst the advantages of [illegible] of construction is the ease with which the furnace can be dissected when a new winding becomes necessary. The same construction may be applied to furnaces containing several wound tubes in the same case, suitable terminals being provided to enable each tube to be used separately if desired. For many purposes a muffle furnace is preferable to a tube, and may be fitted up in the same manner. Special forms are also made in which crucibles of metal may be melted. In all cases the winding, if not overheated, may be expected to last from 1,500 to 2,000 hours before burning out, although this period may be much shortened if there be any strain on the wire or strip. The sizes manufactured vary from 10 inches long and 1 inch in diameter to 3 feet by 6 inches in the case of tubes; and in muffles from 8 inches by 2½ inches to 14 inches by 7 inches by 5 inches, and when an efficient lagging is used the power consumption is remarkably low. Amongst the numerous commercial uses of these furnaces the following are worthy of notice:

Determination of carbon in steel by combustion. In this case the glass combustion tube is placed inside the furnace tube for heating, instead of using gas heating. When many samples are to be tested a four-tube furnace may be used to advantage.

For determining the critical points of steel or for testing the effect of heat treatment at definite temperatures on specimens of metals.

For checking pyrometer readings against a standard instrument, exact regulation of the temperature by an ex-

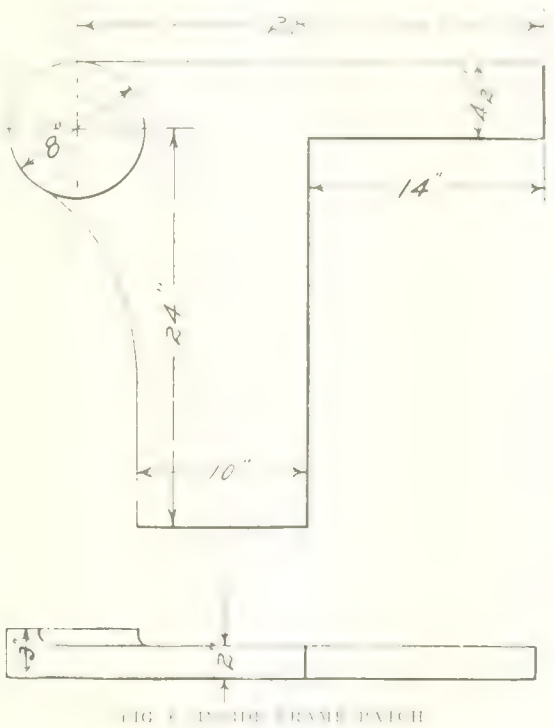

FIG. [illegible] INSIDE FRAME PATCH

FIG. [illegible] CYLINDER EQUALIZER

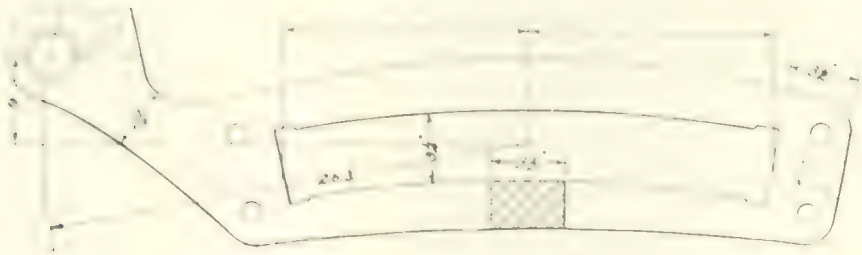

FIG. 8 LOCOMOTIVE SINK.

For general work of this last-mentioned character the muffle form is most convenient, and the clean atmosphere of the furnace together with the precision in temperature obtainable render the electric furnace more suitable for this work than other forms of heating. As an example of modern practice the method of hardening steel articles of a small size at the Packard Company's works at Detroit might be mentioned. A vertical tube furnace, about 2 feet long and of diameter to suit the articles under treatment is raised to the requisite temperature, as shown on the record of a pyrometer inserted amongst the articles. When the assigned temperature has been reached the lower end of the furnace is opened and the contents allowed to fall directly into an oil-bath. This method secures uniformity in result and is clean and economical; and the pyrometer records serve as a check on the work of the operator, besides assisting him in its duties. In British practice the value of the nichrom furnace for work of precision is rapidly being recognized, and under present conditions the demand is much greater than the supply. A satisfactory electric furnace of this type capable of yielding a temperature of 1400 deg. Cent. has yet to be produced.

Such a furnace would prove of great service, particularly in connection with high-speed steels, but at present there is nothing better than an alundum tube wound with platinum. In the hands of a skilled operator such a furnace may give good results, but there is always an element of uncertainty about a platinum winding, and burning out is of common occurrence. Tungsten and molybdenum have been used for special laboratory work, but as these metals oxidize readily provision must be made to maintain an atmosphere of hydrogen round the winding. For special work, graphite or hard carbon tubes may be used through which the current is passed directly, but these also oxidize and could not be used for the heating of steel articles owing to the possibility of chemical action. Refractory tubes, surrounded by granular carbon through which the current passes, have been used for some purposes, but a furnace of this probable that for industrial work of the nature described gas furnaces will still hold the field about 1000 deg. Cent.

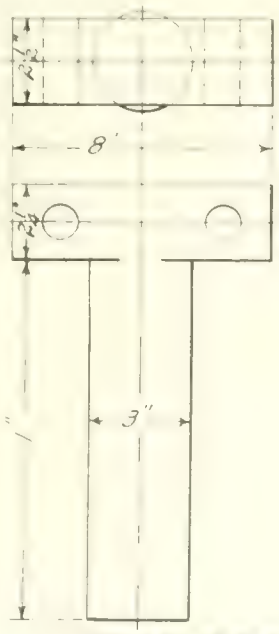

FIG. 9 T-HEAD DRAW BAR

## BRITISH INDUSTRIAL COMMISSION

By Mark Meredith.

The official statement that 267 public commissions and committees to deal with questions arising out of the war have been set up in the British Isles since 1914 indicates to some extent the revolution that the administrative system is undergoing. In itself the practice of administration by committee may be good or bad. It may merely mean gratuitous interference with the work of competent officials; it may mean the effective mobilization of expert knowledge in the service of the State. Of the 267 committees appointed some no doubt have had one effect and some the other, but there is little question that on balance the advantages of the system so extensively adopted have outweighed the evils. Most of the committees are the meeting grounds of the expert, the official and labor, and as such command a confidence which administration by a bureaucracy, however efficient, ca nrarely inspire. Many of them will no doubt cease to be as the particular need they were designed to meet disappears. Some thirty, indeed, have already ceased to exist; but many of them have established a permanent place in the new scheme of things which the war has created and which must outlive the war. But the future of the committee is a comparatively trivial matter compared with the future of the larger machinery of which they form a part.

The great industries of the British Isles—food production, munition, shipping, railways, mines—are to-day in greater degree or less directly controlled by the State and exist only to serve the purposes of the State. The new predominance of public over private interest is an essential in time of war, and few of those who have experienced its benefits will be anxious to revert to the old conditions when peace returns. Changes in the structure of industry may take more shapes than one, and there is no lack in the field of competing doctrines and their prophets. For months, or probably years, after the war, the situation will be largely governed by the necessity for the State control of raw materials, a control that manufacturers and consumers may become increasingly less inclined to abandon. From that path to a system of nationalized production and co-operative distribution is short. That is not a matter to be decided hastily. But decided it must be as a matter of national policy, and it should be now engaging the thoughts of the best brains who are concerned with these problems.

ANTIMONY is extensively employed in the manufacture of ammunition. It is used in the making of chilled shot as well as for most bullet mixtures. Its chief purpose is as a hardening agent. In shrapnel bullets lead is required to give the necessary weight, and antimony is added to make the bullets sufficiently hard to withstand the shock caused by the explosion of the shell. The amount of antimony is from 12 to 25 per cent.

THE Government of Mysore has decided to erect a charcoal blast furnace, according to a recent paper by Mr. H. M. Surtees Tuckwell, and has appointed Mr. Perin as its consulting engineer. He has placed orders for the equipment in America, and the undertaking is to be managed by the Tata Iron and Steel Company. It is proposed to fell and transport timber from the vast forests of Kadur and Shimoga, and convert it into charcoal at Benkipur. Iron ore will be mined at a distance of twenty-five miles, and a high-grade charcoal iron produced. It is also intended that acetate of lime, alcohol and other by-products shall be extracted, and calcium carbide may be manufactured, using the breeze or such portions of the charcoal as cannot be used in the blast-furnace. The plant will be constructed and run by the Tata Iron and Steel Company.

# MANUFACTURE OF THE No. 101 PERCUSSION FUSE

*That the Russell Motor Car Company of Toronto has been largely engaged in munitions manufacture is common knowledge to thousands of people acquainted with the ... thousand employees, or others engaged in trade with the company. The interest of the ... and the varied extent of operations has been such that the directors considered some permanent record desirable, and an official publication "Our Achievement," was accordingly prepared and dedicated to the men and women of the Second Line of Offence. The following article is one of several contained therein, and is reprinted by permission of the company. Illustrations are by courtesy of Southam Press Limited, Toronto.*

THE No. 101 fuse is percussion only, and hence its construction is simpler and it contains fewer parts than the No. 80. The body, cap and adapter—it has no rings—are made of bar steel, and the firing elements of brass. Its operation is as follows: When the shell is fired its forward force causes the detent spring to compress and the detent and detent socket to drop into the detent hole, and catch there. This action frees the centrifugal bolt which is thrown against the centrifugal bolt plug by the rotation of the shell, thus unlocking the percussion, or graze pellet. Hence during the remainder of the flight the pellet is held away from the needle by the creep spring alone. At contact the creep spring is compressed and the burst follows.

### Material

The steel for the body is received in the form of bars 8 feet in length and 2 13/32 inches in diameter. In the manufacture of the 4,500,000 No. 101 fuses by the company over four hundred and twenty-five miles of bar steel were used.

Men do the first operation on the bodies. The steel bars, four at a time, are machined in a multiple spindle automatic screw machine. These rough shape the body, drill the pellet hole and cut the body off to the proper length, a set of operations taking 70 seconds.

After machining, the bodies are washed and inspected, and the burr caused by the boring of the pellet hole is removed by a hand operation. The second machining operation, done by women, on single spindle automatics, is reaming the graze pellet hole and facing the seating surface for the cap. This machine finishes the work on the pellet hole with the exception of cutting the thread for the cap. Time, 50 seconds.

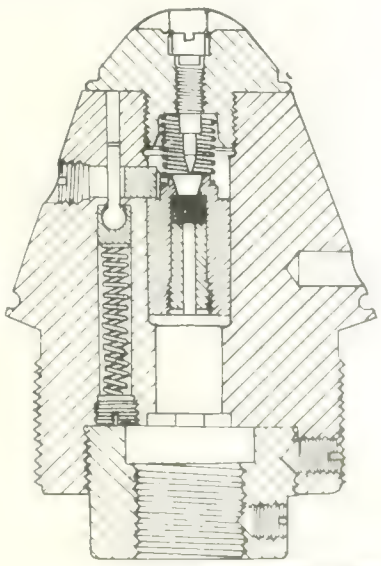
At the completion of the work on the pellet hole the body passes to a battery of turret lathes where the outside tapering surface undergoes three finishing operations. These lathes cut the groove at the base of the taper, shave the surface to absolute size, and cut the knurl. The twenty lathes working on this job have a combined capacity of 35 a minute. The tapping of the thread for the cap, which is a six-second job, finishes the stem end of the body.

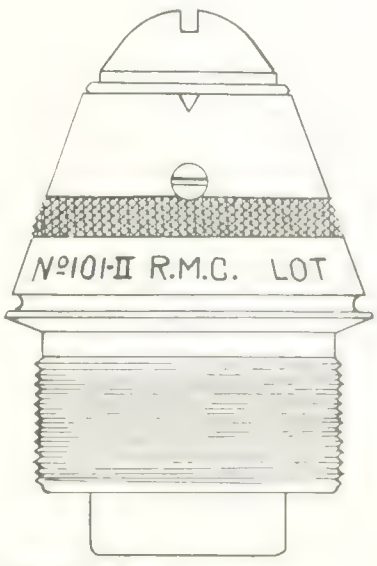
### Drilling Operations

At this point the drilling commences. These operations cover the detent socket hole; the detent hole, a smaller sized extension of the first; the centrifugal bolt hole; a wrench hole, which is used when the fuse is screwed into the shell; and a set screw hole. The drilling of the detent hole is a very delicate operation; until the present method used in the company's shops was devised the results were often unsatisfactory. The difficulty arose from the fact that the detent hole—very narrow and long in proportion—had to be drilled absolutely straight in order for the detent to function properly. After considerable experimentation it was found that the only certain way to drill this hole straight was to use three drills to go a distance of ¾ inch. These operations, shown in the illustration, are similar except for the section of the hole drilled. These drilling and tapping operations teake 6 to 12 seconds each, giving a total time of 2½ minutes a fuse.

There are twenty-one machines doing this work, each with a capacity of three every two minutes.

After the drilling operations a complete shop inspection is made in this department. As in the case of the No. 80





BURRING AND FINISHING BODIES BEFORE PLATING

fuse, there are inspectors overseeing every operation as it is finished. This inspection is carried on the same way as that of the time fuse; and "go" "no go" gauges are used in addition to a visual inspection.

### Thread Milling

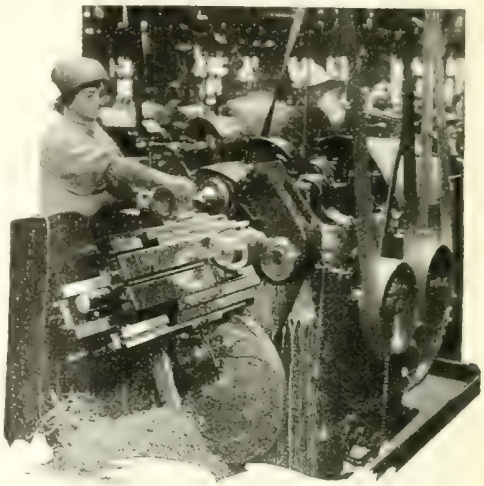
One illustration shows the thread milling operations carried on in this department. These thread millers cut off the thread on the outside of the fuse body which fits into the nose of the shell. The method is similar to that used in thread milling the nose and base of the 9.2 shell. The milling of the outside thread takes 50 seconds and of the inside, which is the same sort of a process, 45 seconds. There are fifty women on each shift employed on these two operations.

Every fuse is stamped with its number, lot, and the initials of the company which made it. The machine stamps everything except the lot, which is determined and stamped on later. Three operators are required to handle this stamping machine, one to feed, one to handle, and one to unload. The skilled workers on this machine are a fine sample of scientific teamwork, and are able to average 1800 every eight hours on each machine with little or no difficulty.

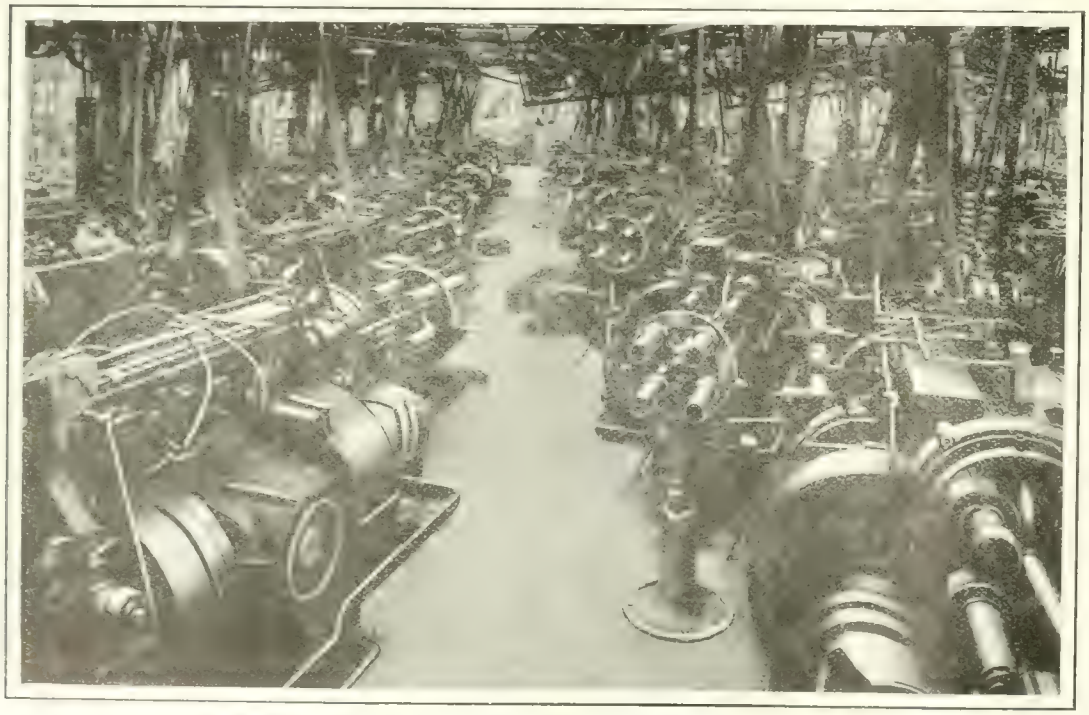
Following the stamping, a large department of finishers take the product in hand and carefully go over it for imperfections. This is the final operation before the plating, and hence the last opportunity for the inevitable inspectors to look for trouble. In this instance the trouble takes mostly the form of rough edges thrown up by the machines, and these are all burred and finished off here.

### Electroplating

As the bodies arrive in the electroplating room they are mechanically perfect, but questionable from the standpoint of cleanliness, due to their passage from oil hands, through oily machines, to other oily hands, to have a "go" in another oily machine. And off this oil must come, and off it does come, for in the company's plant they have very ingenious chemists, who change the oil to soap, and thus make the fuses wash themselves. After they have thus washed off the oil by changing it to soap, they wash off the soap with acid, and then the acid with water.



MACHINING GRAZE AND PELLET HOLES



GENERAL VIEW OF MACHINES FOR BODY MAKING

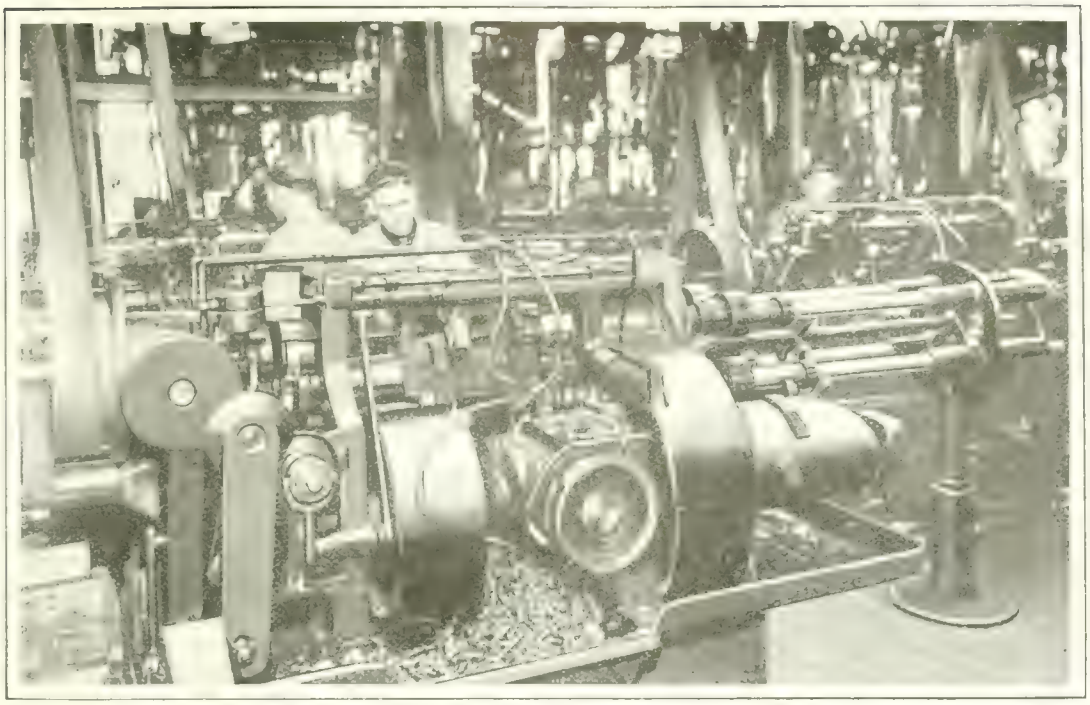
The plating itself consists of hanging racks of fuses in a cyanide of copper solution until sufficient copper is deposited to coast the surface thoroughly. Then they are washed again, first in hot water, then in cold water, then in chemicals, and finally the whole business is blown off clean with an air blast; 26 000 fuses are so cared for each day, as well as nearly 90,000 screws and needles.

One of the noteworthy things about the electroplating establishment is

the manner in which the workmen are protected from the fumes of cyanide. This method, forehanded, like most of the company's methods, instead of drawing off the fumes after they reach air, draws them away as soon as they reach the surface of the solution, so that they never get into the air at all.

### The Adapter

A coupling-pin carries no freight, yet there are few indeed, if any, would disparage its usefulness in the make-up of a freight train. The adapter, the manufacture of which is shown in the two illustrations accompanying, is another one of these bits of apparatus which are more useful for what they get others to do than for what they do themselves.



MACHINING BODIES ON MULTIPLE SPINDLE AUTOMATIC SCREW MACHINES

The purpose of the adapter is to carry the flash which is brought about by so much skill and hard work in the fuse down into the charge in the shell where it causes the explosion. To some extent the work on the adapter, which with the exception of the first operation, is carried on by women, is similar to that on the fuse body.

For the first process, a one and three-quarter inch multiple spindle Gridley automatic forms, drills, reams, bores and counter-bores and then cuts the adapter from the steel rod. This machine operates at the rate of 70 adapters an hour.

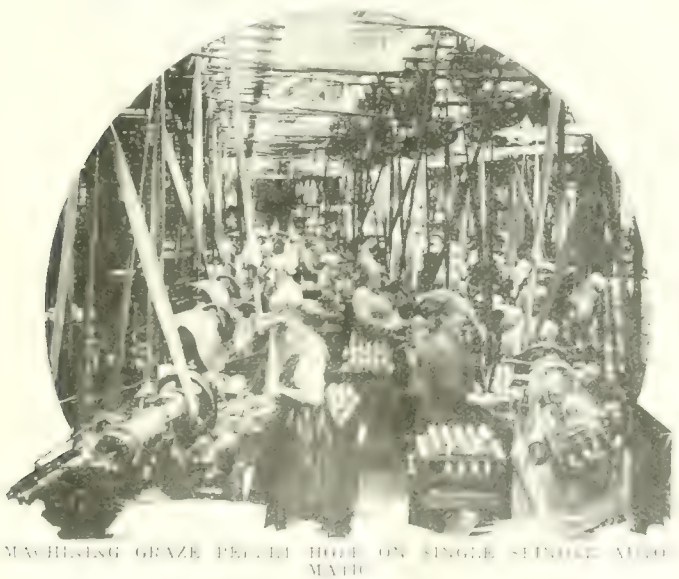
In the facing process the women operators can turn out 3,500 adapters a day. They face the adapter to length and chamfer the bevel on the gaine end of the hole. The remaining operations on the adapter are threading the inside, drilling and tapping the set screw hole, and drilling wrench hole. The illustration above shows the tapping of the inside or gaine hole thread of the adapter. This tap is put on at the rate of one every twenty seconds. A later process re-taps and trues this thread.

### The Cap

The cap, or nose, of the fuse contains the needle which causes the detonation of the charge in the graze pellet. The rough machining and the cutting of the outside thread are done on an Acme automatic multiple spindle machine, with a capacity of 1,400 per twenty-four hour day. Subsequent operations finish form the head and drill and counter-bore the needle hole, a semi-automatic hand screw machine being used; mill the screw driver slot in the head, tap a thread for the needle and burr.

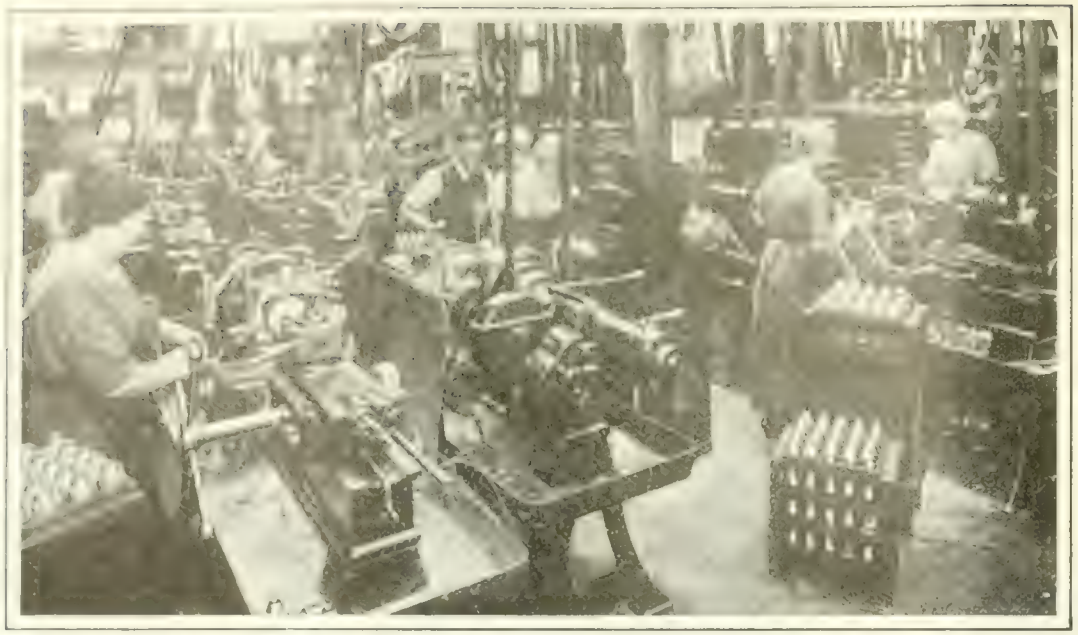
The screw driver slot is milled on a hand feed machine at the rate of approximately 600 per hour. By far the most important operation on the cap is the assembling of the needle. A specially designed semi-automatic is used in this work, and great care is taken that the needle, which is not only threaded into the cap, but permanently affixed with cement, is screwed down firmly and to the proper distance. Its length is gauged from the face of the cap to the end of the needle and only .02 inch is allowed for variation in this measurement.

On the machines shown above are made the numerous small parts that make up the firing elements of the fuses. The automatics on these processes work with as near human intelligence as it is possible for machinery to have. About all that they seem to require is an occa-



MACHINING GRAZE PELLET HOLE ON SINGLE SPINDLE AUTOMATIC

DRILLING CENTRE SOCKET HOLE



GENERAL VIEW SHAVING GROOVIN[illegible] AND KNURLING END OF BODY

sional feeding with another rod or two of brass. Beyond that they work alone. Some of them will do as many as seven or eight different operations. A certain thread is to be tapped, requiring perhaps two seconds. An amusing steel finger jumps into position with a dignified little jerk; it has finished the thread and jumps out of position with an equally dignified little jerk. Two seconds exactly. Another finger, just as prim and methodical, takes its place. This one may mill a slot or ream a drill hole, or machine a tiny surface. Its time allowance may only be five seconds, or perhaps as many as forty. In either case it does its work and goes on its way, while the rest wait patiently their proper turn. And as each unit is finished an uncanny metallic arm reaches down and removes it. Plenty of oil they require, and plenty of material—but of human attention or interference they are more independent than a cat. The automatic shown in the above picture is making graze pellets. It does seven different jobs on each pellet, in fact finishing the pellet except for cutting a slot in the base end, and turns out [illegible] a day.

DRILLING CENTRIFUGAL BOLT HOLE.

### Assembling Detent and Socket

The detent and detent socket are assembled by means of a ball and socket joint — an arrangement which allows the detent to move about freely and thus to catch in the detent socket hole as the spring is compressed. Two girls operate the assembling machine [illegible] press indexing die. One feeds the socket, the other operates the machine with her foot and feeds the detent. They can turn out eight to nine thousand a shift.

The remaining small parts that make up the detent section of the fuse are all assembled by hand, the centrifugal bolt plug, the detent, detent spring, and detent plug screw. The girls working on this can assemble about two hundred fuses per hour. The exact significance of this figure can better be appreciated after you have tried to do the same thing, your temper and your thumb nail in so doing.

### Packing Fuses for Shipment

On account of the long journey the fuses have to make and the hard knocks they are apt to receive before they get where they can give a few themselves, it is necessary that each one be packed in a [illegible] ying room where approximately 25,000 fuses are packed and shipped every day, houses one of the busiest departments of the company's organization.

### FACTORY HYGIENE

By M. L.

It is not possible with any degree of exactness to calculate the influence that hygienic conditions exercise on output. That they have a great influence is generally acknowledged and there is a growing consciousness that the hours of labor and the rate of wages paid are not the only factors that determine the amount of production. More things than food and rest are necessary to make the worker physically healthy, and unless he is healthy in body his thinking capacity will be diminished, and he will be a less valuable asset to his employer than he ought to be. The amount of lost time is usually attributable, in a lesser or greater degree, to the effect of working in a germ-laden atmosphere,

[illegible]G THREAD ON OUTSIDE OF BODY.

and it is to the mutual benefit of both master and man if the factory is wholesome.

It is obviously unfair, as is sometimes done, to blame the factory owner altogether for the conditions of the shop. The workman must share the blame. Mose men are dual personalities. It is a curious psychological fact that men spend about equal time at work and at home, yet, except in rare cases, the habits of the one life do not influence the other. The customs that are considered common decency at home are not observed in the works. The laws of cleanliness are neglected. Workmen expectorate freely on the shop floor or wherever is most convenient, tea dregs are thrown about, oil is spilt carelessly, and dirt of all kinds is left lying about the machine or bench. Of course, the habits of the men are influenced to a

considerable extent by the conditions for which the employer is responsible.

A new factory may be always healthier than an old one, and a great many works want rebuilding, but a clean old building is preferable to a dirty new one. If floors are not swept daily, or several times a day, depending upon the operations performed, it seems futile to be careful of them. There is always a greater inducement to be clean in a parlor than a stable. A great deal depends upon shop discipline. It is a fact that many foremen are so much interested in the skilled workers' efforts that they have not the time to look after the laborers. The laborers are thus allowed to have a free hand and it appears to be human that, unless a man is subject to supervision, he gets lazy. Dust is allowed to accumulate in corners and girders for a twelvemonth. The annual shop-cleaning is [illegible] a custom-

SCRAPING DAY AND NUMBER ON THE JOB

ary affair, but in some cases the dust and filth of all kinds are allowed to lie for years. It is admittedly difficult in machine shops with continually revolving shafts to clean in working hours. Some provision ought, however, to be made for having it done after ordinary

many shops the windows get literally blocked up with dirt, and are never opened either in summer or winter. The work is carried on in a nauseous, un-

close of the day there is a general state of fatigue and work slackens. Good ventilation is necessary to big output.

Many workmen do not leave the shop even during meal hours. They sit on dirty benches or on machine tables and eat their meals. It is quite a common

round a smithy fire, or in a foundry [illegible] drinking black tea out of still blacker cans. Even when dining halls are provided they are not universally used. One cause of this is probably that there is not the same privacy sitting at a long table in a crowded dining hall; but the chief cause, perhaps, is that the workman cannot be bothered with going out of his shop. It is an attitude of mind based on habit and not easily broken. The majority of people are conservative at heart, and do not like to be deprived of what they have [illegible] rights and not privileges. The only way to get workmen into the dining hall habit is to close the shops during meal hours. It would [illegible] employers to have dining rooms, where the workers could either have meals at a nominal price or have their own food cooked. It is a pity that some workmen so often spoil a beneficent employer's endeavors by loitering, and in other ways slacking. In many indutsries wash-

[illegible]

law, and drinking fountains as well, and employers generally would, no doubt, provide better facilities for washing and dressing if it were not for the precautions they find it necessary to take against the unprincipled workmen. These are not in the majority, however, and the man and the master ought to recognize a mutual interest in raising the level of the factory to that of the home.

## TRADE INQUIRIES

THE following inquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained from the Inquiries Branch of the Department:

GENERAL VIEW [illegible]

## THE NEW 320 MM. FRENCH SHELL

By Frank C. Perkins.

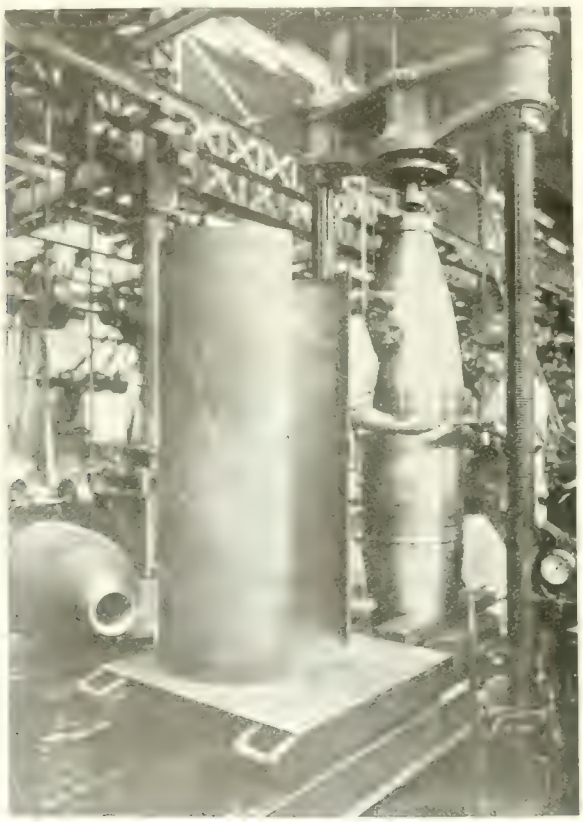
[illegible] at the [illegible] in the works of Schneider & Co. of Le Creusot, France, some of the plants of this steel company being located at Le Havre, Harfleur, and others at Chalon, France. Enormous hydraulic presses ranging up to and more than 1,000 tons are used in producing the [illegible] shells by hundreds of cranes of various sizes, the machining and the tempering equipment and the finishing of the shells and testing them after their completion, are all of the greatest interest. The specification requirements of munition material are very exacting. In France, Great Britain, Canada and the United States, there has been very great appreciation of the benefits to be derived from proper heat treatment of metals going into these shells.

The specifications of the large and [illegible] ridge cases, fuses and pellets are such that very careful tests have to be made of the raw materials and the finished product by the most powerful, as well as the most delicate instruments.

If the brass cartridge cases vary much in the zinc content from 70 copper, 30 zinc, difficulties will be experienced in manufacture and the product will not permit of being loaded three times as specified. The French military specifications considered uniformity so important that they went so far as to specify where the spelter and copper should come from. The reason for this is doubtless the fact that the analysis must be corrected to give a minimum of scrap during manufacture.

TURNING 320 MM. SHELLS IN THE PLANT OF SCHNEIDER ET CIE. FRANCE

The great loads to which this material is put during manufacture under 500 and 800-ton presses, for indenting and heading, necessitates punches made of the best of steel, capable of withstanding approximately 160,000 pounds per square inch. Carbon steel of about 1.25 per cent. carbon was used for the first two sections, as the punches were built up of water quenched sections, heating to 1475 deg. F. and drawing at 430 deg. F. The remaining portion of punches was .90 to .95 per cent. carbon steel.



[illegible] AT THE CREUSOT WORKS OF SCHNEIDER ET CIE., FRANCE.

In determining the capacity of presses required, crushers of brass were made and tested on a Riehle 100-ton testing machine, and from these results the power of presses required was calculated. The pressures required for the operations of cupping and drawing was found to be about 1,500 to 40,000 pounds and 20,000 pounds, while the pressure for stripping after first operation, second operation, and stripping after heading was 3,000 pounds, 11,000 pounds and 16,000 pounds respectively. Scleroscope tests are made from day to day on the material, and the results compared with analyses, and only the raw material which comes within the scleroscope hardness desired are accepted, the others being rejected.

The effect of annealing which is done at 1,200 deg. F. for 30 minutes is remarkable, the hardness increasing as the thickness of the metal decreases.

The specifications for shell steel have close limits. It is possible to use steel of high tensile strength but having good elongation, getting the physical properties by heat treatment. If the steel is hard and brittle, when the shell bursts the pieces break into many small parts, whereas, if the steel is tough, the pieces are larger and the edges are rougher, tending to tear instead of cut, thereby doing more damage.

Attention is called to the fact that the shrapnel shell, while opposing the bursting charge due to its own inertia and being subjected to compressive stress, is also subject to tensile stress, due to the shrapnel bullets inside. In order that these bullets may be thrown forward the shell is designed with a thick wall at the base and this wall gradually tapers off to a thin point near the socket in nose. When the fuse explodes the charge, this thin wall bursts or spreads open, or the fuse threads are stripped. In case the steel is too hard the shock of the explosion in the cartridge case will cause fracture with damage to the gun, and if the cartridge case is too hard, due to excessive zinc, permanent deformation will cause it to stick in the gun and prohibit its use over again after being refilled.

---

**Have Taken Agency.**—Charles P. Archibald & Co., of Montreal, have obtained the Ontario and Quebec agency for the Holyoke Truck Company, of Holyoke, Mass.

# Notes on the Design and Testing of Air Lift Pumps-II.

By A. W. Purchas*

*The air-lift pump has become one of the most economical methods of raising water, the simplicity of construction and the almost entire absence of moving parts giving reliability in operation and avoiding the necessity for skilled supervision. The design of these pumps being subject to more or less development the subject matter of the following article is of more than passing interest.*

### Operation of the Pump as a Whole

THERE are different methods of approaching this question, one of which was given by Dr. H. Lorens. This takes account of friction and slip, but starts off with a "constant" which the tests of Messrs. Davis and Weidner showed to be as variable as any quantity can be. This theory is not reproduced here as it is cumbersome, and does not bring out the features of operation of the pump.

Another method of approaching the subject brings out better than either of the foregoing the details of operation of the process, and may be called the Displacement Theory. Fig. 7 represents the pump prior to the injection of any air. Since the base of the eduction-pipe is open, the pressures on both sides of the horizontal plane X—X are equal, and the liquid stands at the same height inside the pipe as outside.

Fig. 8 represents the conditions after a single bubble of air has been injected. The weight of this bubble of air is negligible when compared with an equal volume of liquid, and the bottom of the eduction-pipe being open the pressure on the two sides of the plane X—X will remain balanced; therefore there must remain in the eduction-pipe after the injection of the air the same volume of liquid as before. The liquid displaced by the air must therefore move upwards, raising the surface of the liquid inside the eduction-pipe above that outside.

Let H be the amount of the rise.

V be the volume of the air bubble,

and A be the cross-sectional area of the eduction-pipe. Then

$$H = \frac{V}{A}$$

The injection of the volume V of air has done work equal to ½VH due to displacement alone, but the bubble will rise through the column of liquid, expanding as it does so and thereby increasing H. Neglecting friction, none of the energy originally contained in the air-bubble is lost until the bubble breaks the surface of the liquid and escapes into the atmosphere. When the air has finally escaped, then it may be said that the energy has been wasted in slip; but not before.

Supposing the air to be injected into the eduction-pipe at such rate that before the first bubble escapes to the atmosphere the total volume accumulated in the eduction-pipe, say $V^t$ is such that the head $\frac{V}{A}$ is greater than the lift L.

Then the pump will discharge a volume of liquid equal to A (H—L). This is the volume that is violently discharged when an air-lift pump is started up. The loss of this volume from the eduction-pipe produces an unbalanced head, equal to H—L, on the plane X—X, which will force more water into the base of the pump. From this point onwards the operation of the pump may be regarded as a head H—L forcing liquid into that area of the eduction-pipe, which is not already filled with air. Analysis of the published results of tests seems to show that the great loss in the pump is not by slip, but of this head H—L due to entry losses.

Tests yielding high efficiency always show either one or both of the following features: low velocity of the rising mixture through the foot-piece, or else a low ratio by volume of air to liquid at this point which is the result of great submersion. The effects of great relative submersion may, however, be offset in many existing wells by the relative high velocities of the mixture leaving the eduction-pipe with consequent high friction losses. All of which suggests that the eduction-pipe should be of as great cross-sectional area as the well permits from its base to at least the level from which the liquid is being raised. The loss by slip of this length is negligible, as we have seen, and the larger the pipe the less will be the loss of the head H—L. Above this point, however, the velocity of the rising mixture must lie between certain definite limits, otherwise the loss by slip will be excessive; therefore the area of the eduction-pipe must bear a definite ratio to the volume of mixture flowing through it. What this ratio should be cannot definitely be stated on the data at present available, but it is hoped that the ideas here put forward may lead to more thorough tests being made of pumps in the future, and the publication of the results.

If the velocity with which the air-bubbles will rise through the liquid can be calculated, then the total volume of air in the eduction-pipe at any instant of time can be found from the known rate of ejection. If this volume produces a head less than the lift, then with the submergence fixed, a greater rate of air-supply must be used for the pump to deliver any liquid. If the rate of air-supply is fixed, then a greater submergence must be provided, in which sufficient air can accumulate to produce the necessary head. A definite volume of air must be accumulated below the water surface inside the eduction-pipe for the pump to work at all.

At the other extreme it is conceivable that the air could be injected at such high rate as to entirely hold back all liquid from entering the base of the eduction-pipe, once the original contents were discharged. Such a state could hardly be obtained in any pump installation, but probably could be brought about with a 2-inch eduction-pipe, 12-inch air-pipe, and high rate of air supply. Experiments bear out these statements, for a series of tests on a pump at increasing rates of air supply show that below a certain rate there is no discharge. Above this point the discharge of liquid increases with the rate of air supply, and then begins to grow less as the rate of air supply is still further increased, Figs. 9, 10, 11.

This Displacement Theory also shows that the volume of air required to raise a given quantity of liquid is independent of the density of the liquid, if we neglect losses from friction and slip. However, the pressure equivalent to the required submersion, and therefore the energy contained in the air injected, varies as the density of the liquid.

### Submersion of the Air Injection Foot-Piece

There is no rational formula known that will determine the most efficient value for the submersion, and only a few published tests touch on the point. Messrs. Davis and Weidner made many small scale laboratory tests which are very inconclusive. Mr. Edmund Ivens also records some tests on a large scale in his book, "Pumping by Compresed Air."

The Displacement Theory, already outlined, shows that the submerged portion of the eduction-pipe is primarily necessary as an accumulator for the air. As will be seen later (pages 25 and 26), there is no such thing as a definite volume of air required to raise a given quantity of liquid to a given height, as the volume of air varies according to the submersion adopted. This conception of an accumulator for the air suggests that greater proportionate submersion is required for low lifts than for high, and that rather than bear a fixed ratio to the lift, the most efficient value will bear a definite relation to the rate of air supply and cross-sectional area of the eduction-pipe.

Current practice favors greater ra-

*Read before the Institute of Electrical Engineers, November, 1917.

as the percentage of submergence increases for all rates of input, and all practical percentages of submersion." It seems quite possible that a rational formula for determining the most efficient submergence may in time be developed from the Displacement Theory.

A Method of Designing Air-Lift Pumps

The writer has taken the data which the larger manufacturers have accumulated, the following method is suggested:

Let L be the lift in feet.

S be the submersion in feet.

$V^w$ be the volume of water to be pumped per minute in cubic feet.

$V^a$ be the volume of air required per minute measured at atmospheric pressure and a temperature equal to that of the water to be pumped.

$P^a$ be the absolute pressure per square inch of the atmosphere.

$P^s$ be the absolute pressure per square inch of the air under the submersion head S.

Then the energy supplied by the air to the water is:

$$144\ P^a\ V^a \log \frac{P^s}{P^a} \text{ foot-pounds,}$$

and the work done on the water is 62.5 $V^w$L foot-pounds.

Then, if the efficiency of the pump were 100 per cent., these two quantities would be equal. In order to apply this method, two assumptions must now be made, namely, the submersion and the efficiency of the pump.

Submersion.—A guide to the probable best value for this has been given already, and these values may be taken, though it will be seen later that they may need modification as the design proceeds.

Assuming these values, then—

$$P^s = P^a + 0.434\ S.$$

Efficiency of the Pump.—This at first seems a very rash assumption, but it is the author's belief that a careful study of this and other papers will show that it is not so. The following test figures stand out as the best so far reported, and analysis of other published tests shows no reason why they cannot always

(1) With the reverse process of compressing air by entanglement with falling water, an efficiency of 81 per cent. has been obtained in Germany, and 71 per cent. at the plant of the Dominion Cotton Mills Co. at Magog, P.Q., Canada. This latter plant was the first installation designed on this principle.

(2) Series D of tests at Oilfields show that an efficiency of 72 per cent. can be obtained with an air-lift pump on lifts of 300 feet, and an analysis of other published tests suggests that in each case higher efficiencies could have been obtained at other rates of working, or by modification of the designs along the lines already outlined. Furthermore, most writers on the subject have in the past conceded that higher efficiencies are obtainable on low lifts than on high lifts.

There is good ground, therefore, for assuming an efficiency of 70 per cent. for all lifts up to 300 feet. This may not be obtained with the first eduction-pipe installed, but in the majority of cases the first eduction-pipe is not the final one, but is installed to find the service pumping level and the capacity of the well. A series of tests made on the first pipe at varying rates of pumping should enable the above efficiency to be obtained with the final one.

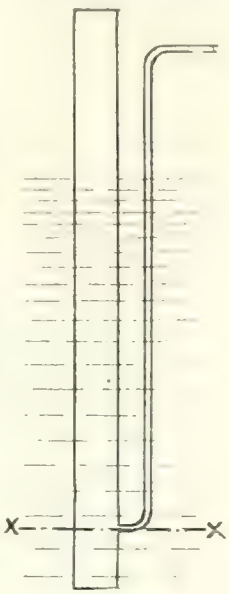


FIG. 7

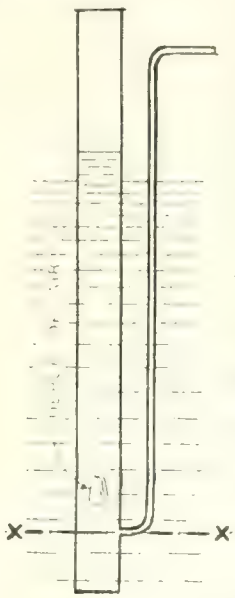

FIG. 8

These two assumptions being made, the volume of air and its initial pressure can be found from the formula:

$$0.7 \times 144\ P^a\ V^a \log \frac{P^s}{P^a} = 62.5\ V^w L.$$

It must be borne in mind that the above volume of air is not the same as the displacement of the compressor-piston. It is usually wise to have a reserve capacity in the compressor to cover such factors as encrusted eduction-pipe, a demand for greater output of water, and wear of the compressor itself. The manufacturers should therefore be given the fullest details, since the power required to deliver any volume of air varies very widely with the speed of the compressor, and the ratio of the desired output to the full capacity of the machine. It may be noted here that high volumetric efficiency alone is not the desirable feature of a compressor, nor high mechanical efficiency alone, but the highest combination of the two. The best machine is that which will deliver the required volume of air at the given pressure with the least expenditure of energy in the prime mover. Some of the latest designs of air-valves obtainable do not promise high volumetric efficiencies, but they conduce to high over-all efficiency.

Reference to the tests in the tables will show that 40 per cent. of the energy generated by the prime mover may be wasted in the compressor itself, and therefore that as much attention should be paid to the choice of the air-compressor as to the design of the eduction-pipe and foot-piece.

Having finally determined the best value for the air-pressure, submersion and volume of air required, the air piping, foot-piece and eduction-pipe can be designed. In proportioning the air-pipe, allowance should be made for the temperature of the air leaving the compressor being high, and the volume therefore greater than would otherwise be the case. After making this allowance, the velocity of the air in the pipes should not be over 20 feet per second. The design of a foot-piece has already been discussed, and will not be repeated here, neither the design of an eduction-pipe along the lines suggested by the Displacement Theory. But to enable others to reproduce the design, of which series D of tests in the tables show the capabilities, the original calculations for this pump are here given:

**Assumptions and Conditions Based on Previous Tests of the Same Well**

Volume water to be raised per second. 0.50 cb. ft.
Volume of air measured at atmospheric pressure and 70° F. required per sec. 3.30 cb. ft.
Lift ..... 300 ft.
Total length of eduction pipe..... 625 ft.
Velocity of rising mixture to be maintained, between .... .... 8 and 15 ft. per sec.
Air pipe to be kept outside eduction pipe.

Available pipe of suitable dimensions:

| Nominal Size | Actual I.D. | Cross-Sect. Area |
|---|---|---|
| | inches | sq. ft. |
| 4-inch line pipe ..... | 4 | 0.087 |
| 5 " 16-inch casing ..... | 5 | 0.136 |
| 6¾-inch casing ..... | 6¼ | 0.210 |

**Calculations**

Pressure of air on leaving foot-piece —141 lb. gauge—3.30 cub. ft. of air at atmospheric pressure, and 70° F., will be 0.308 cub. ft. at 141 lb. per sq. in. gauge pressure, and 70° F.

The increase in volume of the air is 3.30-0.308 cub. ft. in a length of 625 ft. of eduction pipe, equivalent to 0.0048 cub. ft. per foot-length of pipe.

For a velocity of 15 ft. per second in 4-inch pipe, the volume flowing must be 1.305 cub. ft., which in this particular case will consist of 0.5 cub. ft. of water and 0.305 cub. ft. of air. If L be the feet of 4-inch pipe required between the foot-piece and its junction with the next larger size, then:

$$0.805 = 0.308 + 0.0048\ L,$$

whence $L = 103$ feet.

In the next proposed size—5 3-16-inch casing—a velocity of 15 feet per second will require a volume of 2.10 cub. ft., which will be composed of 0.5 cub. ft.

of water, and 1.60 cub. ft. of air. Calling the required length of 4-inch and 5 3-16 inch pipe combined $L_1$, then:

$$1.60 = 0.308 + 0.0048\ L_1,$$

whence $L_1 = 270$ feet,

and the length of 5 3-16-inch required is 167 feet.

At bottom of 6⅝-inch pipe ..... 10.0

Among the more important conclusions to be drawn, which have not been previously emphasized, are the following:

(1) The apparent lack of agreement of different tests with any definite laws is due to two main causes: one, that the volume of air stated to have been used is too often the displacement of compressor-piston, or too high a percentage of this, which introduces an error of 10 to 60 per cent.; the other is the lack of segregation of the losses. For scientific purposes it is obviously useless to lump together the losses in the compression process and those in the eduction-pipe. The former are fairly well understood, but the latter are quite unknown, and will remain so, as long as only tests of the over-all efficiency of installations are made. If the laws governing the losses in the pump proper are to be studied, then a test must give the energy contained in the air immediately after passing through the injection foot-piece.

(2) That the greatest loss in an air-lift pumping installation is in the air-compressor, and therefore that the best compressor is none too good for a permanent installation.

(3) That the next greatest loss is the loss of head at entry.

(4) That any formula for calculating the submersion required would be better stated in the terms of "the volume of air used per second, at a pressure equivalent to the head of submersion," rather than in terms of the lift. This is suggested by the displacement theory conception of the submerged portion of the eduction-pipe as a space for the air to accumulate and raise the water by displacement.

(5) That every ounce of compression which the air is compressed above that pressure, which is equivalent to the submersion head, is so much energy wasted, and that attention should be paid to the design of the foot-piece and the air-pipe with the object of reducing those losses to a minimum.

(6) That a valuable item of information to include in the report of any test is the ratio of the volume of air to water at a point immediately above the foot-piece, and that the ratio by volume of air to water at the outlet of the pump is of little comparative value, since the volume of air is not a measure of the energy contained therein, unless the initial pressure is included in some form.

(7) That the hotter the liquid to be pumped, the higher will be the efficiency of the pump. It has been shown by Professor Randall that an efficiency of 100 per cent. is possible under certain conditions when pumping water at 200° F.

(8) That many flowing oil-wells are in reality "air-lift" pumps, using natural gas in place of air. Mr. A. T. Beazley, A.M.I.C.E., has obtained very encouraging success in making wells flow which had previously to be pumped, by applying to them the principles of the air-lift pump. The great obstacle to be overcome is the lack of control both of the quantity of gas and oil, and of the point of mingling of the two.

(9) That considering the different forms of steam-engine usually used in conjunction with different types of pumps, that the fuel consumption of an air-lift installation can be made to compare very favorably with that of any other type for raising liquid more than 75 feet from a well. For shallow wells centrifugal pumps will probably prove more economical.

Hence pipe desired is composed of: :

[illegible] feet of 4-inch line pipe
167 feet of [illegible] 3-16-inch casing, and
375 feet of 6⅝-inch casing—a total length of 825 feet.

[Note. 6⅝-inch casing is the largest size pipe available which can be inserted alongside the air-pipe in the well.]

Using the above lengths of pipe, the average velocity of the rising mixture will be:

## DEPRECIATION AND MACHINERY ACCOUNTS

By E. P. L.

WHEN a new machine is installed the purchaser usually has a pretty clear idea of the period for which it will last—the "life" of the machine. Obviously if its value will be reduced to zero in ten years it will be necessary to write off the book value during that period. But writing off a fixed percentage from the machinery account every year will by no means meet the case. Suppose for the sake of illustration that all the machines in use have an estimated life of ten years. To write off 10 per cent. from diminishing balances would not extinguish the book value in that period, as the following figures clearly show:

| | | |
|---|---|---|
| [illegible] | [illegible] | First year |
| | 900 | |
| [illegible] | [illegible] | Second year |
| [illegible] | [illegible] | Third year |
| [illegible] | [illegible] | Fourth year |
| | 656.1 | |
| [illegible] | [illegible] | Fifth year |
| | 590.49 | |
| [illegible] | [illegible] | Sixth year |
| | 531.44 | |
| [illegible] | [illegible] | Seventh year |
| Less 10 per cent. ..... | 47.83 | Eighth year |
| | 430.47 | |
| [illegible] | [illegible] | Ninth year |
| | 387.42 | |
| [illegible] | [illegible] | Tenth year |
| | $348.68 | |

Instead of extinguishing the original $1,000, only about two-thirds has been written off, leaving $348.68 still standing as an asset.

The satisfactory handling of depreciation off plant and machinery demands the use of a special inventory. This may be ruled to provide for insertion of the following particulars:

Date acquired.
Description of machine.
New or second-hand.
Purchase price.
Estimated life.
Annual depreciation.
To be written off by (——)
How disposed of.
Value extinguished.

The last two columns are, of course, only used after the period representing the life of the machine has expired. A tick placed in the last column—"value extinguished"—shows that nothing more has to be written off in respect of this machine. To ascertain the total amount of depreciation to be written off at the close of the financial year the separate amounts shown in the inventory are tabulated and added together.

If preferred the tabulation can be made at the same time as the entry. In this case a rather wider book is needed, the particulars quoted above being recorded on the left-hand side of a double page, and the right-hand page being ruled with a series of cash columns to be headed with successive years. Thus, if the book value of a machine purchased at the beginning of 1917 is to be extinguished in five years, one-fifth of the purchase price is extended into each of the columns headed 1917, 1918, 1919 and 1920, and 1921. The accuracy of the analysis is proved by the totals, the sum of analysis columns on each page being equal to the purchase total on the corresponding half of the sheet. A summary of the page totals gives the amount to be written off each year.

## RECLAIMING PACKING AND OIL

By C. T.

In these days of waste elimination, some attention should be given to the renovation of packing in axle-boxes, and the reclaiming of oil, and investigation and experiment suggest two distinct processes by which this can be done, whilst in practice it has been found that a scheme can be made a success.

In the first of these processes the packing as it is taken from the journal boxes of cars of any description should be placed in a cylindrical drum, the outer surface of which is made up of wooden slats, with internally projecting spikes of great sharpness between 5 in and 6 in. in length. The rotation of this drum with the packing inside serves to pick it thoroughly apart, and allows the short strands of waste, particles of dust and dirt, odd bits of metal, and other foreign material to be sifted out between the slats and to fall into a receptacle underneath the drum.

When this operation has been carried on for some time, the waste is removed from the drum and is placed on an inclined table having a slatted bottom. The picking is continued further with a fork until the mass is entirely free from lumps and such foreign substances as may not have been sifted out in the picking machine. The lower end of this inclined table rests on the edge of a steam-heated oil vat about 3 feet wide and 8 feet or 10 feet long. The picked waste is placed in the oil, which is maintained at a temperature of approximately 100 degrees, and the whole mass is agitated by forking for an hour. This operation serves to wash the waste thoroughly, freeing it from dirt and congealed oil or grease and restoring it to its original resiliency. At the opposite end of the vat there is an air-operated compression strainer. The waste, after being forked in the vat, is put through the strainer, which is arranged to press out only such a quantity of oil as to leave the waste of the right consistency for use in packing journals.

The reclamation of oil presents greater difficulties, as the ordinary forms of oil filter do not adapt themselves to the extraction of the usable oil from the residue pressed out of the waste, and the secret of the trouble may be found to lie in the specific gravity of the material brought in for reclamation. As this material is usually full of dirt and other foreign substances it is usually heavier than the water employed in the filters, and those filters which depended upon flotation on water to separate the oil from the dirt prove to be inadequate for the work. In place of this method it will be found that distillation will give good results. The residue from the picking machine is first put through an air press similar to that employed for conditioning the renovated waste. This residue consists of dirt, granules of babbitt metal, short fibres of waste, etc., and is treated to free the oil thoroughly of foreign substances. No satisfactory method has as yet been devised for reclaiming the babbitt. After a sufficient quantity of oil has drained from the press it is thinned by the addition of ordinary kerosene or signal oil. The still used is heated by steam and the condenser is water-cooled. When the still is put in operation the first material to come off is the kerosene or signal oil used as a solvent, and this is followed by the lubricating oil, which is in perfect condition ready for use. The still is then cleaned of any remaining residue and is ready for the next batch of oil. After about one week's operation the oil in the washing vat becomes too heavy with dirt to act satisfactorily in treating the waste; it is therefore thinned in the same manner as the residue and distilled, this process fully restoring it to its original value for waste washing purposes. A saving of $2,000 per annum can be effected by the use of these two methods.

## SHIPBUILDING IN AUSTRALIA

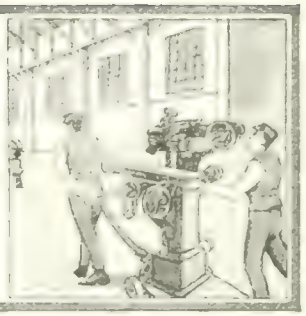
RECENTLY the expert engaged in England to supervise the Commonwealth Government's shipbuilding scheme arrived in Australia and is now completing his examination of the various federal, state, and privately-owned plants and yards. It is anticipated that an early start will be made with shipbuilding within the Commonwealth.

The Commonwealth Government has extensive yards at Sydney; the State Government of New South Wales has a plant at Newcastle, and the State Government of Victoria has extensive yards at Melbourne, all of which (independent of the federal shipping adviser) are managed by competent steel shipbuilders with practical experience in British yards.

It is announced that there will be sufficient steel in Australia to build seven steamers. At the outset some imported materials will be used, but the bulk of the steel will be supplied by the Broken Hill Company's steel works at Newcastle, N.S.W., which, with subsidiary or associated companies, will ultimately be in a position to furnish all the structural steel for the framing and plates required for the construction of steamers in Australia.

The work will be apportioned to the yards in the several states, and, while no authoritative statement has yet been made as to the size and class of the steamers, it is considered by experts having knowledge of the facilities available that the initial vessels will be about 330 feet long by 48 feet beam, with a carrying capacity of about 3,500 tons.

# DEVELOPMENTS IN SHOP EQUIPMENT



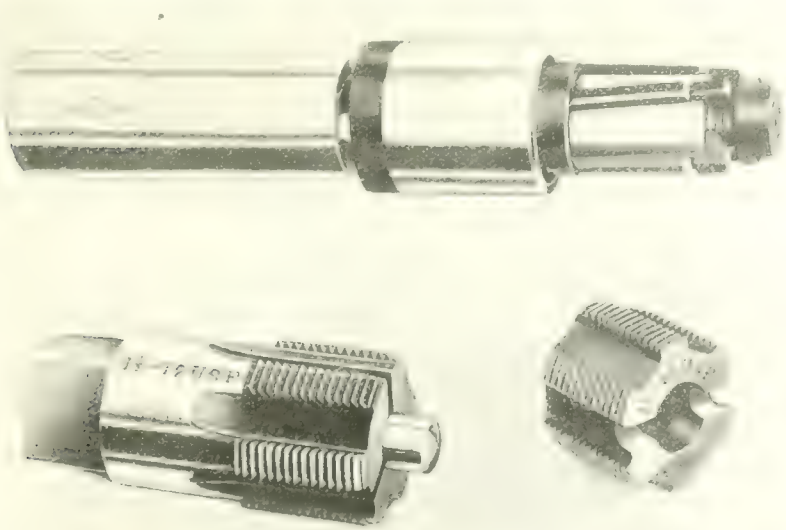
*Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

## NEW DEVELOPMENT IN SIZING AND CUTTING TOOLS USED IN MAKING BRITISH SHELLS

IN the making of special tools, such as tapes, reamers, and gauges used in munition production, there have been more developments during the past few years than in the previous century.

The accompanying illustrations show a number of taps and an expanding reamer of the floating type for finish sizing of fuse holes of shells, which represent additions to the Wetmore line of products, made by the Wetmore Mechanical Laboratory Co., of Milwaukee, Wis., and handled through its Canadian agent, H. E. Streeter, New Birks Building, Montreal. In the design of these taps experience gained through the making of taps since the first munition contracts were brought to Canada was drawn upon, and thread shapes chosen which have given longest life and accuracy.

The expanding reamer is of the floating type, the one shown made to fit a 2 in. turret hole and designed for finish sizing fuse holes of British high-explosive shells. This reamer floats freely in its socket, is self-centering, and insures the reaming of a true round hole. The blades are set on a left hand angle to eliminate liability of chatter. To take up the wear of blades they are expanded by means of two ground nuts. The blades may be removed and replaced without taking the tool apart, and a true center in end of reamer makes it possible to grind the blades in place if desired. Expanding reamers of this type are shipped with the blades ground to dimensions required by manufacturers.

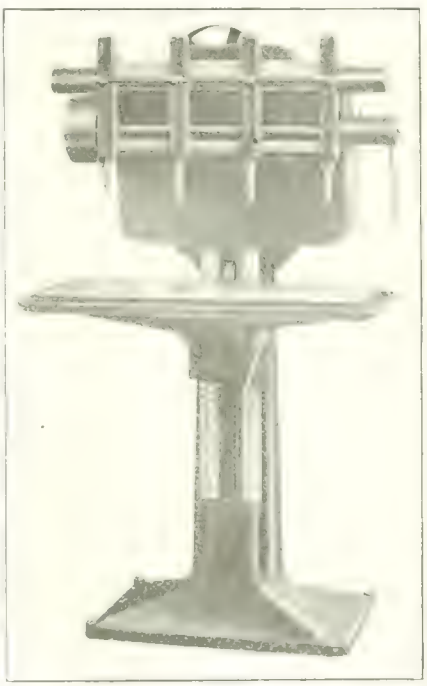


TAPS AND FLOATING REAMER FOR FINISHING SHELL FUSE HOLES

## VALVE GRINDING MACHINE

The valve grinding machine illustrated herewith is a recent product of the Defiance Machine Works, Defiance, Ohio. This machine will grind all the valve seats in a gas engine cylinder block, of various types, at one time, and is made with four, six, or eight spindles. Special heads can be furnished to grind the seats of the staggered type of valve. All that is required of the operator during the grinding operation is to press lightly on a lever to hold the valve head drivers down against a regulated spring tension. This, however, may be accomplished automatically by making provision in the cylinder holding fixture. The oscillating motion of the spindles, together with lifting and returning the valve head drivers, is entirely automatic. It rapidly grinds valve seats to a perfect bearing.

The table, to which fixtures for holding cylinders are clamped, is rigidly gibbed to the base column. It is provided with a binder screw for clamping at any position on the column. The weight of the table, when raising or lowering, is relieved by counterbalance concealed in the core of column. Sufficient weight and strength has been properly distributed to withstand severe strain and maintain perfect alignment during a long period of use.

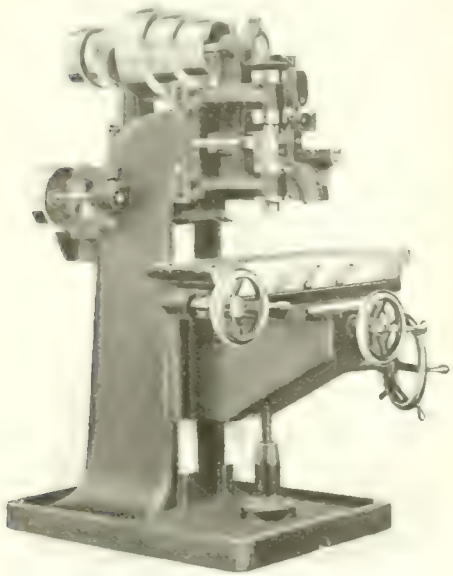


DEFIANCE VALVE GRINDING MACHINE

The spindles are ground true and fitted in sleeves. They ride on a race of ball bearings at both top and bottom ends. This arrangement effects a free and easy oscillating movement to the spindles. The spindle heads are securely gibbed to the top frame. Adjustments are obtained by a screw leading through the head; each head is moved independent of the other, and provided with jam nuts on each side to hold them in

ting movement to the spindles in this machine is a new departure from other methods used heretofore and an exclusive feature. This movement is obtained motion to the drive rack, and eliminate These parts are encased in a tight housparts of this machine are enclosed to protect the operator from injury.

Fixtures for holding cylinders to the table and drivers for oscillating the are furnished only at extra cost. The drivers are made with tension to beat The driving points are made special to engage the valve heads as provided for. A two-horse-power motor is sufficient for the operation of either the four, six or eight spindle machines.



DIE SINKING MACHINE

## DIE SINKING MACHINE

A die sinking machine of wide adaptability and usefulness, made by the Jackson Machine Tool Co., Jackson, Mich., is described herewith. The machine was primarily designed to reduce the cost of drop forging dies and to thus extend the use of drop forgings to embrace many pieces made of iron or steel castings. Any die with one or more circular impressions can readily be routed out on this machine with considerable saving in time and with resulting economy.

Dies, such as crank and cam shafts, knuckle joints, can be machined in one setting, and all typing on semi-circular impressions is entirely eliminated.

In general design and range the die-sinking machine resembles a vertical miller, but is provided with an additional head for cutting semi-circular impressions in drop forge dies.

to take up wear. The thrust is taken up on upper bearing, thus equalizing the friction. The spindle is provided with No. 11 Brown and Sharpe taper. It is mounted in a housing which swings on hinges. When it is in use, the housing is bolted securely to head by two large bolts, and the nuts on bolts in hinges are tightened, thus making it part of the headstock. The power is transmitted from cone shaft through mitre gears as shown. When the secondary head is not in use, these bolts are removed, and the entire spindle housing is swung out of

The secondary c cherrying head is a segment of a gear operated by rack shown in above illustration which carries a cutter shown herewith. The centre of cutter is the true centre of segment. The segment oscillates 40 degrees each side of centre, and on the return stroke the housing is raised three-sixteenths of an inch, thus clearing the cutter. The segment is provided with circular ways and the wear on same is taken up by circular tapered gibs. The oscillating motion is obtained through a rocker arm and crank shaft, and the raising or relieving motion is obtained by a cam on the end of the crank shaft through levers and links.

The working surface of the table on the No. 5 machine is 13 x 40 in., the longitudinal travel is 32 in., the cross travel 12½ in., and the vertical adjustment 17 in.

The table on the No. 6 machine is 13 x 48 in., the longitudinal feed 40 in., the cross feed 13 in., and the vertical feed 21 in. Both machines have three 11/16 in. tee slots in the work table.

The hand wheels are so located that an operator can reach them all from one position. Each wheel is provided with a micrometer dial reading in one-thousandths of an inch.

The vertical spindle is of large diameter. The lower bearing is 2⅝ in. x 5¼ in.,; the upper bearing 2⅛ in. x 4 in. Taper bronze bearings are provided to take up wear. The thrust is taken up on upper bearing, thus equalizing the friction. The spindle is provided with No. 11 Brown & Sharpe taper. It is mounted in a housing which swings on hinges. When it is in use, the housing is bolted securely to head by two large bolts, and the nuts on bolts in hinges

CUTTER USED IN SECONDARY HEAD

are tightened, thus making the housing part of the machine frame.

Cutters are furnished in sizes from ¼ in. to 4 in. diameter.

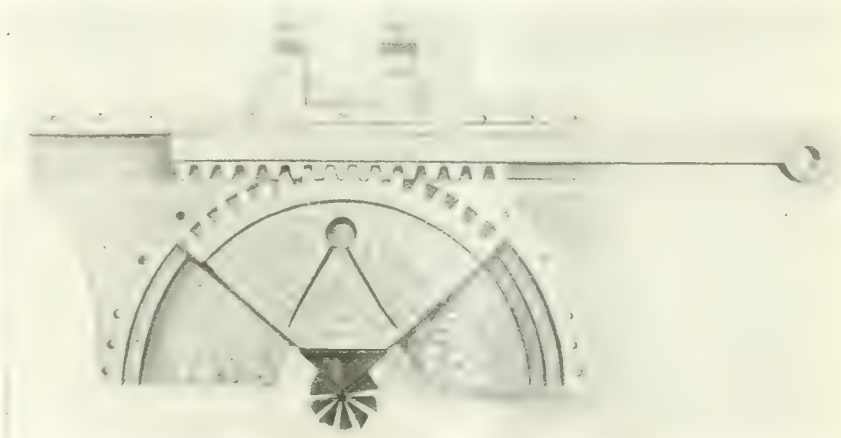
## THE DRAWING OFFICE AND OUTPUT

By Mark Meredith.

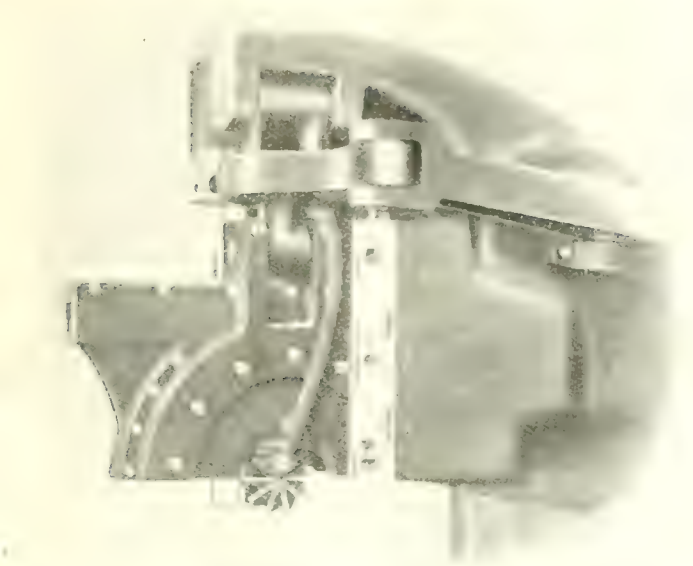
The great factor to-day is output, and output will be of the utmost importance for some time after the war, and any suggestions to help output are worth consideration.

The drawing office plays a very important part in output. The machine or structure is dealt with first in the drawing office, and every detail should be thought out with the ideas of rapid production. It is well known that production in quantities means cheapness and quick output, so that the standardization of parts should be carried out to its fullest extent. It is the drawing office that must see to this standardization.

This standardization should be carried



SECONDARY OSCILLATING HEAD WITH CUTTER IN POSITION.

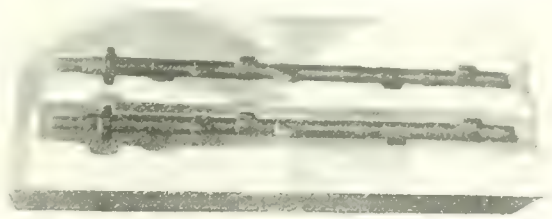


CLOSE UP VIEW OF SECONDARY HEAD

[illegible] office should adopt a distinctive type of drawing and adhere strictly to it; for this, although seemingly a small matter, tells in the end. The drawings should be made in specified sizes, and a smaller size to suit the general type of work for smaller details.

Adopt as far as possible certain scales only—say, full size, 3 inches and 1½ inches for details, and 1½ inches and ¾ inches for arrangements. Each drawing should bear a title, drawer number, and note of the scale to which it is drawn. All these particulars should be most clearly marked on the drawing in one particular place—say, bottom right or left-hand corner, the best position being the bottom right-hand corner, as this is convenient when turning over drawings in a drawer. The type of marking title, etc., should always be the same, and for this reason and distinctness a stencilled title is much better than one printed by hand. The letters should be bold, of block type not less than a ¼-inch high. The drawing number should be larger if anything—say ⅝ inches high. The denominations of the various views should also be stencilled on in preference to printing. The various views should also bear the same relation to each other on every drawing—that is to say, the plan should always be either above the side view on every drawing or below the side view on every drawing. The correct position for the plan, on the principle of hinged planes, is below the elevation, and an end view, looking from the left end of the side view, should be drawn on the right-hand side of the right view. In some offices the reverse view method is used, namely, the end view is drawn at the end of the side view from which it is projected. Whichever method is employed, it must be strictly adhered to; this point is most important, saving many mistakes and much time.

Views must be so arranged that they do not overlap. It is not usual now to send tracings into the shops, blue or other prints being used, so that the actual finish of the drawing itself is not particular. When prints are used, the tracing becomes the drawing office record, and for this reason and also for the benefit of the shops it is essential that the tracing be most carefully made. [illegible] the draughtsman makes his own [illegible] others tracers [illegible] tracings he need not be so particular in the finish of his drawing. He need not dot lines or stop them off exactly as required, as he can easily do this when tracing. If a tracer is employed the drawing needs more elaboration, and time is often taken up in explaining the drawing or making alterations and corrections afterwards, so that the advantage is with the draughtsman who makes his own tracings. Again, in the tracing a distinctive style must be followed. Good black lines, with dotted lines of uniform thickness, should be used, and dots as equal as possible in length; centre lines somewhat thinner and broken, not dotted. By using broken lines for centre lines there is not the possibility of confusing them with the dotted lines. Projection lines for dimensions should be also thinner than the main lines, and in long and short lines distinct from dotted and centre line. Dimension lines should be thinner than the main lines and continuous, with just a break about the middle. In the break the figures should be placed, not above the dimension line. In putting the figures in the line there is no doubt as to which dimension the figures refer to.



DIE MADE WITH DIE SINKING MACHINE

The figures must be very distinct and bold, especially on any drawing which has to be used in the smithy. In some offices the practice is to put all dimensions up to 24 inches in inches and parts or decimals; but as fitters generally use a 12-inch rule or straightedge, the better practice is to put dimensions in feet, inches and parts or decimals. If the decimal system is used the dimensions look and read better in inches and decimal parts. All parts that require machining should be distinctly marked, the best method being by putting a red line along the surfaces to be machined. This red line is put on the print after printing, of course, but care must be taken that the tracing is marked exactly as the print, so that the record in the office agrees with the shop drawing.

Some "fit" and allowance system must be adopted to suit the class of work done, and the drawings must be marked to show which fit has to be worked to. These fits may be to the British standards system or a private system, but the shops must know exactly what fit is required. Allowances must not be left to [illegible] much time is saved when a standard system of fits is used; the workman knows exactly what to work to, and has not to consult the foreman, draughtsman or anyone else. Each drawing should also bear a schedule giving the various parts covered by the drawing and showing the number of each part, the material of which the part has to be made, and a reference letter being stencilled on the particular detail referred to. Sectional parts should be cross-hatched by continous or broken lines, or by brush lines on the tracing. There is no need to use different kinds of hatching to denote the material of which the detail is made, as this is specified on the schedule. All tracings should bear a consecutive drawing number and drawing number. Tracings should be classified in some suitable manner, according to the classes of work, and put into drawers accordingly. The tracings should be placed in the drawers in consecutive order, and when one is taken out a card should be left in its place stating who has taken the tracing and the date on which it was taken. In every drawing office there should be charts giving the maximum capacities of the different machines, furnaces, stock sizes of milling cutters and other articles.

Just a word of advice to draughtsman. Never be too proud to ask advice from a foreman in the shops—you do not know everything.

## DARING DORA

The Defence of the Realms Act, or D.O.R.A., as it is familiary termed, is the subject of judicious jest on occasion by British journals. The lady is extremely sensitive, however, as indicated by a contemporary who understands that a well-known service journal in England is to be proceeded against for publishing news calculated to convey information to the enemy, the said news being important details of the plans for perfecting the carrier pigeon service, by crossing pigeons with parrots, to enable verbal messages to be carried.

## ARE THERE TO BE WOMEN MECHANICS?

THE question as to how far women have permanently replaced men in industrial pursuits is a problem which recurs with increasing frequency, and will probably not be finally settled until factories have settled down to after-war conditions.

Until conditions become normal, that is when munitions and other essential military work cease to occupy any great proportion of the world's activities and most of the armies have been demobilized, a larger number of women will be employed in engineering shops than are likely to be retained permanently. This is so, not only because men will some day be returning for whom work must be found, but because present conditions are not really competitive.

As long as a certain fixed price obtains at which more or less continuous contracts for very similar articles, such as shells can be had, and where patriotic considerations render the question of profit secondary to that of delivery, to which must be added an occasional real dearth of male help, women will continue to be given employment.

In endeavoring to forecast the future accurately, let cognizance be taken of the fact that few women have taken the place of really skilled mechanics whose duties involve a knowledge and understanding of machinery which cannot be given through intensive tuition for a short period.

A description of fuse manufacture, in which women figure largely, appears in this issue, and the very fact that they have been so successfully employed at once raises the query as to how much other work they could do as well. As machine operators and semi-skilled mechanics they would have a field later, provided quantity output enabled suitable equipment to be used, but at present their appearance is due to both extraordinary expansion of business and the peculiar fitness of the product.

Work involving the performance of rough and heavy duties by women means that special labor-saving devices would have to be supplied, and just how many smaller shops would be willing to do so when a supply of male help was available which did not require such equipment is problematical. Add to this the competitive feature and the probable variety of work to be handled and the necessity for experienced men with apprenticeship training becomes at once apparent.

No amount of cramming or parrot-like operation of handles, levers and belts will ever make mechanics out of women. The path is long and onerous and many fall by the way, even though they should be men.

## SOME FEATURES OF RECONSTRUCTION

CANADIAN students of reconstruction problems and possibilities are doubtless aware of the activities of the British Ministry of Reconstruction, but to the layman whose interests confine his attention more to home products it may be surprising to learn that the various commissions and committees appointed in England since the war began now number 87 and form 15 groups.

The extent of the control exercised by the Ministry will be gathered from the group names: trade development; finance; raw materials; coal and power; intelligence; scientific and industrial research; demobilization and disposal of stores; labor and employment; housing; education; aliens; legal; miscellaneous.

A feature of such work is that while nominally organized for reconstruction, much of the work now being accomplished is of direct value to the conduct of the war. Trade conditions are, of course, subject to war influence and cannot be altered pending the outcome of the struggle, but much national effort which comes under one or other of the groups has been of marked assistance in hostilities.

The development of cotton growing; coal conservation; fuel and coal storage research; engineering, metallurgy, mining and glass and optical instruments; abrasives; lubricants and lubrication; civil aerial transport; all of these sub-divisions have produced results of value to date.

The question of abrasives is of interest to Canadian manufacturers because the supply and preparation of these materials for the output of lenses and prisms for optical instruments for war purposes has been of great importance.

Possible developments in civil aerial transport loom large in the future of this land of long distances, and the intentions of the British Government in this respect are of prime interest in view of the large proportion of Canadians in the flying forces. The committee under the Air Ministry is to consider (1) the steps which should be taken with a view to the development and regulation after the war of aviation for civil and commercial purposes from a domestic and Imperial and an international standpoint; (2) the extent to which it will be possible to utilize for this purpose the trained personnel and the aircraft which the conclusion of peace may leave surplus to the requirements of the naval and military air services of the United Kingdom and overseas dominions.

## PRIVATE INTERESTS TAKE SECOND PLACE

IT has been rumored and denied that the War Industries Board may take over all of the steel plants in the United States and operate them under government control.

Such a scheme would be a not unnatural development of the government's experience with railways and shipbuilding, and may have been suggested by the recent decisions regarding national arsenals; a second plant is to be established by the Midvale Steel & Ordnance Company, similar to the Neville Island plant of the Steel Corporation. This latest plant will be located at Nicetown, Pa., and may run to $50,000,000 before being fully operated.

The close interest in the steel industry thus acquired by the government may have brought the final development much nearer, and in the event of such taking place, the industry is expected to undergo some degree of stabilizing which cannot be expected with private ownership.

The desire to earn the approval of shareholders by conducting operations so as to avoid too large excess profits taxes has not been conducive to production, consequently the necessity of getting the most good for the most people may compel private interests to subside for the period of the war.

Few people are really aware of the exact meaning of efficiency: something for nothing is a well-defined term for the idea in the minds of some people—many people figure their own efficiency in direct proportion to how much they can get for how little they can do. The converse of course applies to some employers, and the continued existence of such sentiments has resulted in a sinister reputation for the word efficiency when applied to human endeavor.

# HOLDS PATENTS ON MANY IDEAS HE HAS PERFECTED

**L. A. Desy, Consulting Engineer at Lymburner's Ltd., Montreal, Has Had an Interesting And Varied Career**

"WHEN you ask me about some of the special work that I have successfully completed, and the inventions that I have been interested in, you are requesting something that, if told in full, would fill many pages." Thus spoke Louis Arsene Desy, Consulting Engineer with Lymburners Limited, of Montreal, Quebec, when speaking to a representative of CANADIAN MACHINERY some few days ago.

LOUIS ARSENE DESY.

He has been applying his inventive abilities to the science of engineering ever since his early school days. Born in 1856 in the Quebec town of St. Cuthbert, county of Berthier, of French - Canadian parents, the "boy" received his early training in the Normal School and the Joliette College. After a short period of practical experience in architectural offices in Montreal, Mr. Desy, at the age of 24, decided to go West, accepting and filling the position of architectural and mechanical engineer in several offices in St. Paul, Minn. In 1882 he opened an office of his own in the City of Winnipeg, acting as architect for the C.P.R. and also the Hudson Bay Company, and during part of the five years he was located there he also filled the position of City Engineer for the town of St. Boniface, across the Red River from Winnipeg.

The lure of the West, however, was not sufficiently strong to hold him, so that in 1888 he returned to Montreal, opening an office as a consulting engineer. In the year 1896 he accepted a position as assistant engineer at the Harbor of Montreal. Speaking of his work in this connection, Mr. Desy said: "For several years they had been having trouble with some of the construction work and I had been consulted on different occasions. After serving one year in the junior capacity I was appointed Mechanical Superintendent of the harbor dredging and construction, occupying this position until 1902. Much of the modern construction of the harbor piers and channel dredging was performed under my personal supervision."

About this time his abilities as a resourceful and successful engineer were recognized by the authorities at Ottawa, and he was induced to accept a position as consulting and construction engineer with the Public Works Department. Successful effort seldom goes unrewarded and on the recommendation of the heads of the Department he was selected by the British Government and engaged in 1905, for four years, to carry out an engineering undertaking in the central portion of Northern India. The work required was the dredging of a considerable portion of the Jhelum River in the Valley of Kashmir. The actual operation of deepening the channel was not an unusual undertaking but the construction of the dredges, under the existing conditions, was anything but an easy problem. During the four years occupied in this work, he made three trips to India, the first time to study the situation and design the necessary dredges, leaving his assistants and the natives to construct the wooden hulls and framework while he returned to America to obtain the necessary equipment and machinery.

The mechanical equipment was made by Bucyrus Co., of South Milwaukee. In citing some of the difficulties of transportation Mr. Desy said, "The machinery for the entire five dredges was taken from Milwaukee to New York, to England, transferred to another steamer and thence to Karacchi, India, placed on cars and taken inland to Rawal Pindi, a distance of about 1,500 miles. From here we had to use bull-carts to transfer the machinery across the Himalaya Mountains for nearly 180 miles to Baramusla, this last portion of the journey occupying over three weeks. No serious hitch occurred throughout the entire trip; it required 120 days from the time the equipment left Milwaukee until it was unloaded in the Kashmir Valley."

The five dredges were all operated by electrical equipment, the power being generated at a station ten miles below the scene of operations. The dredging work included the removal of about 10,000,000 yards of earth, and the five dredges were capable of taking care of 10,000 cubic yards per day, 15,000 h.p. being utilized in the operation of the machinery. The designing, construction, transportation and operation, was personally supervised by Mr. Desy during the four years of his engagement. A year or two after his return to Canada he received a letter from the engineer in charge, Major A. J. de Lotbiniere, R.E., commending him for the efficient manner in which he had successfully carried out this engineering achievement.

On his return to Montreal he became associated with G. W. Harris in the manufacture of excavators, these machines being designed and patented by Mr. Desy. Many of these are now working along the St. Lawrence River and other water ways.

At the outbreak of the war he became interested in the development of machines for shell making, designing, constructing and patenting many tools that have proven their exceptional efficiency for rapid and economic operation. After making shells on his own account for about two years, he associated himself with Lymburner's, Limited, or as he put it himself "Lymburners bought out my entire equipment, machinery and man, I being retained as a consulting and designing engineer." For the past two years he has devoted his energies to the developing and improving of various special machines for the different types of shells. These machines include cutting-off, facing, turning, boring, profiling, multiple saw, billet breaking machine, and various others.

Mr. Desy has been interested in many inventions, his first patent received being for a caterpillar tractor ditching machine, obtained in 1885. He has also obtained patents on dredges, steam shovels, and many types of metal working machinery. He is now 62 years of age and still hale and hearty, has three children, two sons and one daughter, one of the boys being attached to the Royal Flying Corps.

He is a great believer of technical study for the young and old mechanic. "To keep pace with the rapid developments that are constantly taking place in the field of engineering," he said, "it is essential that the ambitious workman or engineer keep in continual touch with the advancements that are daily taking place in the mechanical world. To do this effectively it is imperative that he not only study the problem of his own line of activity but that he should become familiar, either by observation or by the medium of a reliable trade or mechanical paper, of the general problems and difficulties of other mechanics and engineers. Very often an article in a technical publication has been the source of many an inspiration."

Mr. Desy is a member of the C.S.C.E.

# MARKET DEVELOPMENTS

## Outlook Poor for Non-War Industries

### Plants That Cannot Line Up With the War Group Have Little Chance in the Iron and Steel Market—Plate Prices Take Advance and Are Once More on the Old High Level Basis

THE future is not promising for the shop that cannot qualify as a war industry, but which still finds it necessary to have supplies of iron and steel. In some cases these factories have already reached the stage where they must simply mark time until the war appetite for these things has been satisfied. In other cases they have been able to sub-let from war contractors, and in this way line up with the war group. The war standard is being more rigidly applied than ever to every order that comes into the market, and Canadian firms are showing a commendable desire to co-operate with the War Board in seeing to it that the priority order is made completely and effectively operative.

The production of coke at American points is regarded as highly satisfactory, also the output of steel ingots and of pig iron. In fact capacity production is almost the rule now at all points and the logical step of increasing capacity is now being undertaken on a large scale. The situation in United States parallels that in Canada as far as the commercial use of steel is concerned. The firm that is counting on coming into direct competition with the war group for a supply of raw material is going to have poor skidding for some time to come.

Makers of machine tools for war purposes report business as being very brisk. The placing of new orders continues, and in many cases the shops handling these are in the market for new equipment, in others it is simply a case of tooling for another size of work. Demand is brisk for all classes of high speed and carbon goods—in fact everything that enters into the equipment of munitions plants is sought after.

Scrap metal yards are well filled, but with a class of goods in many cases that are not much sought after at the moment, viz., of the non-ferrous sort. Cuttings and scrap that can be turned over to munitions plants, in fact anything in the nature of low phosphorous metal is needed, but very scarce. Much the same condition prevails in United States where prices for some lines are much higher than in Canada, but the embargo on scrap holds all the stock in this country that is originated here.

Prices for steel plates took a $20 per ton advance this week, coming back to the high level on which they have been based for some weeks past. For a few weeks they were quoted at nine cents per pound, but the recent order forbidding purchases for warehouse purposes has brought the price sharply to the ten cent per pound mark, and there are very few indications of it receding.

The metal market is rather uninteresting, the only point about which there was any discussion being the price of copper, and the action of the War Industries Board in the United States makes it plain that they intend to continue the 23½c price for another three months. The high-cost mines have apparently failed in trying to bring pressure on the government to induce them to increase the price to their level of production costs. The low cost mines are apparently doing very well at the 23½c mark.

## REVIVAL OF MUNITIONS BUSINESS MAKES BRISK DEMAND IN MONTREAL

Special to CANADIAN MACHINERY.

MONTREAL, Que., May 28, 1918.—The feature of the week is undoubtedly the revival of the munitions industry. This had been on the wane after the general withdrawal of the British shell orders, especially those of the heavier calibre, but the recent activity has been additionally emphasized as a result of fare new orders. To handle this business many Canadian plants have commenced operations to enlarge their present capacity. Lvalls of Montreal have already started the erection of a new plant for the production of the 155 m.m. shell, and within a very short time the firm of Caron Bros. are expected to start operation on a new plant for the same size shell. It has been intimated that the Canada Cement Co. will do their own forging on their contract for the 9.2 inch shell. Machine tool business has been stimulated by the announcement of recent and further shell activity, and the demand for shell machinery has become quite heavy. It has been announced that little passenger traffic will be carried on from the Port of Montreal this summer and that all activity will be confined to the transportation of freight and other essential supplies for overseas purposes; this only applies to transatlantic traffic.

### Steel

An undercurrent of uncertainty appears to pervade the local situation in connection with the possibility that the near future may see some sort of arrangement leading to price control of steel and other commodities. For this to be put into force it will be necessary that the co-operation of the American Government and the producers be effective with the authorities at Ottawa, in order that the same may be placed upon a working basis, owing to the fact that the bulk of steel now used in war preparations must be brought in from the States. The tendency has been to create an unsettled market. The requirements of Canadian shipbuilders have been arranged for through the joint action of the Canadian and American Governments. Shell steel requirements have been greatly increased owing to the heavy additional orders placed and Canadian producers of shell steel are working to capacity. Much of the steel required for the shells to be made for the American Government will be brought in from the

States. While the present demand for steel virtually excludes the buying for ordinary purposes, it is anticipated that after the bulk of the building of munitions and shipbuilding plants has been completed there will be sufficient material available for considerable domestic activity, although the high cost under existing conditions may prevent other than absolute essential enterprise from bein proceeded with. Dealers here report a quiet market with the situation confined to war activities exclusively.

### Metals

Aside from the recent announcement regarding the renewal of the copper price, the market has not been featured with any special development. Production in some instances has been interfered with owing to the inability of maintaining sufficient labor at the mines and refineries, but this condition has had little effect as yet on the consuming market. Little complaint is offered as to transportation and delivery under the existing conditions is almost normal. Copper has become steadier following the decision to maintain the previous fixed price. Tin is still very scarce and supply uncertain. Spelter is quiet on poor demand. Lead is inclined to weaken under decline of demand. Antimony and aluminum are quiet and unchaned.

**Copper**—Although some disappointment has been expressed over the attitude of the American Government in reaffirming the price that has ruled for the past several months, the general opinion appears to be that the decision to carry on at the old price is very satisfactory to the majority of the trade, both as respects producers, dealers and consumers. The time effective for the renewed price will expire about the middle of August so that those advocating a higher price will have an opportunity to advance further claims before that date. As a result of the recent announcement the market has become steadier here and increased activity has been shown, but little business is being carried on outside of war requirements. Local dealers report a quiet market with prices unchanged at 29 and 30 cents per pound.

**Tin.**—This metal continues to hold the center of interest owing to the uncertainty that prevails in the situation both here and abroad. Some relief has apparently been given to the London market as indicated by the most recent quotations but the change has, as yet, not been reflected in the transactions here or in the States, where the situation is still exceptionally strong, with nominal quotations holding. The scarcity here is still marked and the demand is active, but dealers are unable to supply the metal, the result being a very strong market. The market is a nominal one and the general price asked by local dealers is approximately $1.35 per pound, an advance over last week of 10 cents per pound.

**Spelter.**—The situation has not improved and the existing demand is very light, although slight interest has developed over the report that considerable buying has taken place on the other side for government requirements; this, however, has not stimulated outside buying, and the tendency is for an easier market. Dealers here are still asking last week's price of 10 cents per pound.

## POINTS IN WEEK'S MARKETING NOTES

**Firms in non-war lines requiring steel and iron are finding it increasingly hard to keep in operation.**

**The demand in Canada is still very pronounced for machine tools for the equipping of new war order shops.**

**Canadian agents for British high-speed steel find it hard to secure anything like definite delivery of orders.**

**Carnegie Steel Corporation is now operating 51 of its 59 stacks. Last winter the number was down to as low a figure as 29.**

**The scarcity of coke in the United States is now regarded as being almost at an end. Recovery ovens are being gradually added to in many districts.**

**There is no improvement at U.S. points in supplies of steel for ordinary commercial purposes, nor does there promise to be any improvement in the future.**

**Every week tends to add to the amount of steel that U.S. War Board and allies are calling for.**

**Rumor that U.S. would soon commandeer all steel plants in U.S. is promptly denied at Washington.**

**Copper prices in United States will very likely remain at the present standard of 23½c according to announcement by the War Industries Board.**

**An increase is noted this week in plates, tanks and heads of $20 per ton, due to difficulty in replenishing stock.**

**There is a good market for low phosphorous scrap, but there is little offering at the moment either in United States or Canada.**

### Machine Tools and Supplies

Present indications point to a renewal of considerable activity in the machine tool industry as a result of the increased business that has followed the placing of large shell orders in Canada; these contracts call for a range of munitions variety. Dealers report a heavy demand for all classes of shell equipment, particularly those required for the production of shrapnel; inquiry is also quite heavy for the 155 m.m. shell and likewise the larger sizes. A feature of the present demand is the marked activity in connection with the buying of used machinery. Quite a brisk business is being done in general equipment. Inquiry for electrical machinery has developed to a large extent owing to the changes that are contemplated by many firms in changing over from steam to electric power for the conservation of fuel. The revival of the munitions industry has also renewed the demand for all classes of supplies; this is very noticeable in connection with the cutting tools required for the different makes of shells. Manufacturers and dealers in carbon and high-speed tools report a heavy demand during the past few weeks and anticipate still further activity. Delivery in some instances is somewhat uncertain but this applies to those steels that are required to be imported; local manufacturers are in a position to take care of the demand on very good delivery. Prices in all lines are well maintained, and in some quarters the tendency is to higher levels.

### Scrap

The quiet tone of the [illegible] situation is still maintained and dealers report little activity of a general character. The apparent scarcity of pig iron has resulted in the absorption of greater quantities of cast iron scrap, and the market in this material is very strong and active; local quotations are now $34.00 per ton, an advance over last week of $3.00 per ton. The demand for wrouht iron scrap has been heavy and the price offered for scrap pipe has been advanced to $22.00 per ton. Zinc and lead is in less demand, and this has been followed by a decline in the price of scrap metal, both of these have fallen off [illegible] cent, and the respective quotations are 6 cents and 7 cents per pound. A steady business is done in heavy melting steel [illegible]

### PATENTS ISSUED

The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—Frank Garrett and Harry K. Pratt, safety controlling gears for electrically propelled vehicles; Wm. M. Brownell, apparatus for drying and similarly treating materials; Robert Donald, method of storing micro-scopic slides; James C. Doust, potato-planting attachment for plows; Isaac L. Leo, pneumatic tires; Harry A. Matear, shock absorbers for boots or shoes; Dunlop Tire & Rubber Goods Co., Limited, liners for pneumatic tires; Edward J. Wild, collapsible boxes; C. N. Garner, collapsible boxes; Thos. G. Gilbertson, boot trees.

# HARD SKIDDING FOR NON-WAR INDUSTRY

**Simply Has to Mark Time While Steel Output Goes to War Industries**

TORONTO.—The extent to which the steel plants in Canada are endeavoring to co-operate with the authorities in seeing that war needs have priority over all else is evidenced in several ways. A circular has been issued by several concerns to their customers calling attention to the absolute necessity of the strictest observance of the decrees calling for the entire output of steel for war purposes. One of these sent out to-day has this clause: "Under the circumstances it will be necessary that you state in your orders whether this material is needed for government use, advising government order number and stating also under which of the following classifications the work comes: Ships, aircraft, military or naval supplies and operations, or for buildings directly connected with the above. If the material is not for government use, give us accurate and detailed information as to its ultimate use, as there are many other essential industries, fuel, food, clothing, etc., necessary to the welfare of the country, whose requirements should be given every consideration after the needs of the government."

And in the same course of events, there is a number of war industries that are feeling the pinch now as they have not before. They have not been able to whip their business over into a war essential, and therefore the securing of supplies has been made well nigh impossible. Many of these shops have been able to keep going on the strength of certain sub-contracts secured from the men who have war contracts. In many cases, though, the outlay necessary to do this is larger than the firm can stand or the sub-contract will warrant, and there is nothing to be done except to pass under the war shears for the time being and mark time until the day when commercial requirements in the steel and metal markets will have a respectable chance of being filled again.

Brantford and London seem to be centres that are attracting considerable attention just now by reason of the large war contracts that have been secured by firms in these centres. As in several of the Toronto and Montreal contracts there are some shops in these places that will need entire equipment, their plant not being convertible to the big shells that they are going to turn out, previous runs having been made on the 4.5 and 5.2. The demand continues very brisk for big machine tools, and in proportion the supply business is prosperous.

As was to be expected the order from the War Board forbidding the purchasing of plate for warehousing has had the effect of making prices for stock in hand firmer, and to-day several advances are quoted in plate, ¼ to ½, also heads and tanks. The increase works out at $20 per ton, and puts the price back to the figure where it has been for some time with the exception of a few weeks, when the selling was on the lower level.

Scrap markets are not active. Dealers in some cases keep on purchasing non-ferrous metals in order to protect their credit, not because they want to stock up any more with these lines. There is very little scrap reaching the dealers that can be turned over to the war order shops, and of course that is where the great demand is at the moment.

**Plate Prices Up**

There is a very firm tendency in the steel market regarding the trend of prices. As was predicted in these columns some days ago the prices for plates have advanced, the quotation to-day being back at the $10 mark, against a $9 figure which local dealers have been accepting for some time. This works out at $20 per ton. "Some weeks ago," stated a dealer to-day, "we were getting shipments through in very good time, and the quantities were quite satisfactory. On that ground there was a tendency on the part of dealers to go out after business a little more aggressively and to put prices on a lower level as the stock coming in had been secured on a better price than the old. When the order from the War Board came through a week or two ago that put an end to all that, and it was only a matter of time until there would be a rise in prices. We are simply stepping back to the old figure."

It is out of the question that the same volume of business should be done this year as last. Dealers don't expect it, as there is not the field to do business in.

**Scrap Metals**

The dealers in scrap metals find their yards increasingly stocked with lines that are not particularly in demand at the instant. The cuttings from war work generally pass back at once to the control of the War Board, and little of this is ever dealt with in the open market through the yards. The prices being paid in U. S. points, where there is also an acute shortage of desirable scrap, are higher than the Canadian figure. For instance shell ends across the line are quoted now at $40, the figure here standing at $24, being a spread of $16 on that item between the two markets. The embargo on scrap prevents the shipment of any stock here to American points. There are no price changes this week.

**Machine Tools Wanted**

War work is still behind the demand for machine tools, especially of the heavier order, and local dealers are sharing freely in the new business that has been originated on that score. The Dominion Steel Products in Brantford, and the Motor Trucks, of the same place, are both in receipt of orders of very large proportions, and are busy putting in the necessary equipment. London orders are also creating considerable new business. Along with the installation of new plants there is the increasing volume of trade for supplies and sundries for plants already in existence, and trade in all lines of equipment is very satisfactory. Prices are firm, very few changes showing either way in the lists this week.

**The Price of Copper**

The belief expressed in these columns some weeks ago by a well known Toronto dealer that copper prices in United States would not be fixed beyond the present figures on June first seems to have been well founded. Indications

# DEVELOPMENTS ON LARGE SCALE ARE PROCEEDING AROUND WINDSOR

Special to CANADIAN MACHINERY.

WINDSOR, May 27.—Good progress is being made by the Great Lakes Dredging Co. on the docks for the Canadian Steel Corporation at Ojibway, near Windsor, Ont. The contract for the dock and dredging alone involves an expenditure of about $2,000,000. The contractors are employing about 160 men. P. J. Harrity, superintendent for the contractors, told CANADIAN MACHINERY that he hoped the work would be completed before the freeze-up, but this would depend upon the schedule arrival of piles and other material.

Considerable piling has already been done, piles from Georgia and British Columbia being used on the work. When the piling has been completed, the concrete work will be started and the docks dredged out. A large steam shovel is already excavating at one section of the property. The dock will be 2,100 feet long.

No work has yet been started on the steel plant proper, but plans have been prepared and work on the foundations will be commenced this summer. Considerable preliminary work has been done in regard to laying out the site and construction of roadways.

**Building Extension**

The Swedish Crucible Steel Co., of Windsor, Ont., is building an extension to the foundry, 100 x 100 feet, and also a new machine shop, 75 x 100 feet. Both buildings will be of brick, steel and concrete construction, and steel sash. The company is specializing in cast steel tractor wheels and other tractor castings for the General Motor Corporation of Pontiac, Mich., and Stockton, Cal. The new foundry will be used exclusively for this class of work, and the latest equipment is being installed for the purpose. The wheels will be moulded in three large Pridmore machines and the two International moulding machines will be used for making the cores. The capacity of the plant will be greatly augmented by the installation of the new equipment and will enable the company to meet the increasing demand for its product.

have yet to make their appearance that would lead one to look for higher fixed prices than those now prevailing. The group of high-cost mines were behind the pressure for the raising of the limit, but it does not seem likely that they will be able to sufficiently impress their views on the War Industries Board to raise the limit. The War Industries Board, in advance of June 1, has already indicated its intention of retaining the 23½c limit for a period of another three months. The government has not made any move to fall in with the suggestion of paying a differential rate. There are too many obstacles in the way of such a course. It would mean paying a high cost mine perhaps a thirty cent rate; one operating under better conditions about 25 or 26, and one producing under favorable circumstances the minimum of 23½c. It is easy to see that such a plan would create a heap of trouble and an immense amount of discrimination that the authorities are not inviting in the present instance. There has been a feeling all along that there is no good reason why the small producer or the high cost mine should set the pace for the purchaser of copper.

Other lines in the non-ferrous market remain stationary in price, and a fair volume of trading is being done.

## RAILROAD PRESIDENTS FALL BY THE WAYSIDE

**Policy of United States is Being Put Into Effect Without Fear or Favor**

Special to CANADIAN MACHINERY.

WASHINGTON, May 28.—The United States has gone over the top in an industrial way. From the reports coming from all of the government departments interested in the production of war materials it is shown that for the first time since the war came to the United States production is assuming proportions which are comparable to the vast resources of the nation.

Ship production is progressing rapidly now. An announcement from the Shipping Board shows that one wooden ship a day has been turned out for the past few weeks. Steel vessels are being delivered almost as rapidly. One of the great drawbacks in the shipbuilding program has been obviated and that is the lack of transportation. Reports of the Railroad Administration and the Shipping Board show that there has been a great speeding up in the delivery of cars for the use of transportation of shipbuilding materials.

Production of ordnance is also coming along better now than ever before, although the ordnance program is admittedly far behind what most of the leaders would desire. Steel supplies have been gathered and the entire steel resources of the nation have been directed to war purposes and there is every reason to believe that production of ordnance will soon reach a point where there will be less need for drawing upon the ordnance manufacturing facilities of France and England.

### Control of Steel?

There is a persistent rumor, coming [illegible] that the War Industries Board is about to take over all of the steel plants of the United States and operate them under government control. It is known that this plan appeals to Bernard Baruch, chairman of the War Industries Board, and it is understood that he is strongly in favor of such an act. President Wilson, however, holds the power to do this and there has been no indication from the White House whether or not the President would approve of such a plan. It is argued by many of the industrial leaders in the government that such action is necessary in order that the greatest production of steel may be attained. Already the steel manufacturers are in a voluntary agreement to divert their entire products to the uses of the government, but it is held that there are many difficulties arising which private owners can not cope with as the government could. The matter of labor is one which the government might better be able to handle than the private owners. The matter of profits is also a stumbling block to production, some close to the head of the industrial leadership declare. They point out that the desire of manufacturers to produce in such a manner that they will not be compelled to pay too large excess profits taxes has in some degre affected production. This is not considered a matter of greed, but merely a matter of good business and an attempt to make the best showing possible to the stockholders.

### New Revenue Bill

Business men throughout the entire United States are already beginning to adjust their business to meet the proposed new revenue bill. Secretary of the Treasury McAdoo has given notice that there will be a need for an addi-

## BELIEVES THERE IS A GREAT FUTURE AHEAD OF STEEL BUSINESS AFTER WAR

W. D. Ross, vice-president of the Nova Scotia Steel and Coal Co., has returned to Toronto after spending some time at the properties in the East. In referring to the talk of a deal whereby the Scotia and Dominion companies would come together in a merger, Mr. Ross stated very definitely that the proposal was out of the question now. "It is absolutely off," was the way he stated the case to CANADIAN MACHINERY.

The development of the property of the company at Wabana is progressing in a very satisfactory manner. Slopes have been driven through to the iron ore deposits in such a way as to insure the maximum amount of production, and it is contemplated that these beds will be delivering ore in the month of September.

### The Future of Steel

"I have no two opinions in regard to the future of the steel business in Canada," stated Mr. Ross. "My contention is that for almost four years the steel companies of the world have produced very little of a real or permanent nature. You may argue that the plants are all running to capacity, but what is being done with the capacity production? It is being largely sent to the bottom of the ocean or shot off in the air. We are living in a period of destruction, and it must of necessity be followed by one of construction. The railways of this continent are not being kept up to the mark of efficiency by any means. Many of them are using equipment right now that in ordinary times would be well on to the road to scrap. It is being kept in use because it cannot be replaced because of the pressure of war business. Commercial lines have been cut off almost entirely for a long time. There is practically no structural work being carried on, no bridge building, and none of the ordinary lines that use commercial steel are operating to any extent. It will take years to get the world back to the normal point again. One has only to stop and think for a few moments of the amount of reconstruction work that will have to be done in the countries of Europe where the war is raging, to see what a demand there will be for steel and steel products for years to come. There may be a lull after the war for a short time, and it looks to me that in that period the steel interests would be well advised if they put their house in order to meet the tremendous expansion that is bound to take place afterward."

### The Coal Situation

Mr. Ross went on to state that the operation of the Military Service Act was making it a difficult matter for the coal producing companies in Nova Scotia to keep up their output. "The best miners we can secure," said Mr. Ross, "are the natives of that province, who come to the mines when they are young and learn the business thoroughly. A real coal cutter is no man of a few days' training. It takes a long time for them to learn the mining, and it is the men who know it well who keep up the production end of the business. When a miner is drafted it means that production is going to suffer to the extent of that man's ability to produce, because he can't be replaced from the present labor market. The taking out of iron ore is another matter, because the men there are not up against the dangers of mine gas, and it does not require the training that it does to make a good coal miner."

The coal for shipment will likely be the first item to suffer, as the first call on the coal will probably be for coking purposes to keep pace with the production of iron ore.

[illegible] ness. It is believed that the bill will [illegible] amount will be taken in the form of [illegible]

[illegible] German railroad presidents are now being replaced in favor of regional railroad administrators. These administrators will assume full control of railroad affairs in their respective districts.

[illegible] and Loss

Reports of coal production for the [illegible] were 11,806,000 net tons of bituminous coal produced against 11,554,000 net tons the previous week. The production [illegible] however. This was due largely to a coal shortage. Various mines reported that their production was cut on account of [illegible] shortages reported to the Fuel Administration ran from 14 per cent. to as high as 59 per cent. The week of June 3 has been designated as Coal Week and during that week every effort will be made to produce the maximum amount of coal and to move as much coal as possible. Householders will be asked to have their winter stores in by that time. The Canadian Fuel Administration will be asked to co-operate. The Fuel Administration has given notice that supplies of anthracite coal will be reserved for domestic uses and that it can be used only for industrial purposes after the domestic needs have been filled.

The Bureau of Supplies, Navy Department, Washington, D.C., announces that it will call for bids for bolts, nuts, gauges, pipes, and other miscellaneous hardware and machine parts. Those desiring to offer bids may secure specifications by writing for schedules 1813, 1806, 1812, 1808, and 1817.

Supplies of oil and gasolene are being more carefully hoarded in the United States now than ever before. It is expected that before the summer is over the Fuel Administration will take drastic steps to restrict the use of fuel oils of all kinds. Already yacht and private boat owners have been warned that the Fuel Administration expects to issue an order preventing the burning of fuel oils on pleasure craft.

Appointment of a mineral administrator, to control the supply of industrial minerals, is being urged in Washington now. The Senate has already been informed that it may be expected to act [illegible]

---

THE Sahara has been crossed by aeroplane, according to the "Echo de Paris." Half of the trip had formerly been accomplished, but three machines have now completed the entire distance in seven hours without landing.

# RAISING THE LIMIT EVERY MONTH NOW

## Ingot Steel and Pig Iron Production Are Reaching Enormous Totals

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., May 28—Production continues to increase in both pig iron and steel. The Carnegie Steel Company, easily the largest single producing company, has put one more blast furnace in operation in the week and is now operating 54 of its 59 stacks. For a few days last winter it was down to 29 furnaces actually in operation, many being entirely out of blast while a number were banked. The company's pig iron [illegible] is now running at 91 per cent. of capacity and its steel ingot capacity at 93 per cent. of capacity. The fact that these percentages are so close together indicates that the company is fairly well supplied with scrap, despite the extreme scarcity of most grades of scrap in the open market. Without a full supply of scrap the steel production could not make as good a showing in proportion to the pig iron supply. It may be surmised that, as is the case with many steel producers, much shell discard steel and other material is being melted up for scrap by reason of the requirement of the government that there be maximum production of war steel. Otherwise the shell discards could in large measure be rolled into various merchantable products, including light rails, concrete reinforcing bars, bedstead angles, etc.

### By-Product Coke

The scarcity of coke is now almost completely ended. While shipments of Connellsville coke are running at only about 340,000 to 350,000 tons a week, that is a gain of about 100,000 tons a week over the average in the early weeks of the year, and there is aid from some by-product ovens that have been completed and put in operation. The beehive coke produced, moreover, is of better quality. When car supplies were so irregular coke frequently had to be held in ovens 96 hours and longer, at the expense of quality.

New by-product coke ovens completed since the first of the year represent about 1,600,000 net tons of coke a year. Ovens to be completed in the next two or three months represent about 4,750,000 tons a year. Three additional contracts have just been let, involving ovens that will be rushed to completion as rapidly as possible, the three projects being 128 ovens at Clairton, in addition to the 640 ovens now almost completed, and which will begin making coke next month; 300 ovens for the Jones & Laughlin Steel Sompany, Pittsburgh, and 110 ovens for a merchant plant at Fairmont, W. Va., the three plants having a total capacity of about 2,150,000 tons a year.

These and the other by-product coking plants can be counted upon to operate practically full next winter. Interruptions to coke supply last year were a matter of transportation, chiefly of [illegible] coke from beehive ovens. Two points are in favor of the by-product ovens, that the government is vitally interested in getting the by-products, and that the by-product plants can store coal in large quantities while with few exceptions they are located adjacent to the blast furnaces they serve. Thus it looks as though restriction in iron and steel production from shortage of coke is about ended and is not going to return. There has been very little restriction in output from any other cause.

### New Price Regulations

Within the past few days changes have been announced by the Institute committee in charge of iron and steel prices. These relate chiefly to differentials for charcoal iron and silicon irons, and to extras for certain descriptions of tin plate and formed sheets. One important thing, however, is strictly new, and that is the adjusement of the band situation, which the hoop and band mills have claimed right along was very badly handled in the original price fixing. Bands had formerly been sold, as a rule, at the same base price as merchant steel bars, having of course their own list of extras. Hoops were sold at a separate base price, with their own extras, running from 13 gauge up, while the band card ran from 12 gauge down. The original prices fixed were 2.90c for both bars and bands, and 3.50c for hoops. This made it that 12-gauge bands were placed very much lower than 13-gauge hoops, and for a time at least the mills practically refused to sell bands. There is some reason to believe that they sold a material not visually distinguishable from bands, but designated by a different name and with a price that was derived from the hoop base price.

Under the new ruling hoops and bands are both put at the base price of 3.50c, with a new card covering all gauges. From 13-gauge up this card is practically identical with the old hoop card, while 12-gauge down it is practically identical with the old band card, minus 20 cents per 100 pounds, or $14 a ton. Thus, in substance, the base price of bands has been advanced $12 a ton and the extras reduced $4 a ton, making an advance of $8 a ton. There are some slight divergences, but in general these figures represent what has occurred.

### Steel Supplies

There is no improvement in supplies of steel for ordinary commercial purposes. One cannot place new orders for steel, or secure deliveries of steel already on order, unless there is involved either a war order or an activity that will clearly aid very materially in prosecuting the war. There is quite a free distribution to industries that have already been given a clear preference, including the oil trade generally and the agricultural implement makers.

The joint committee appointed May 17, representing the government and the steel makers, is hard at work endeavoring to improve the situation and in particular to secure the fullest information

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

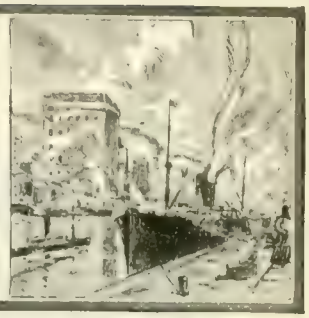
# INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES



## ENGINEERING

Chatham, Ont.—W. H. Westman, of this city, has recently purchased the Exeter Mfg. Co., of Exeter, Ont., and [illegible] parts of the plant to Chatham. He will sell the balance of the machinery. The equipment that will be moved to Chatham will be installed at the Chatham Malleable & Steel Co.'s factory, of which Mr. Westman is the proprietor.

## MARINE

**Washington.**—Prohobition of the use of fuel oil for private yachts for the duration of the war is under consideration by the fuel administration.

**Port Arthur.**—Workmen at the Port Arthur Shipbuilding Company's plant broke the Canadian record for keel laying. Exactly two minutes after the rope was cut which launched the Osiris, three plates of the keel of an ocean-going freighter had been put in place on the blocks vacated by the other vessel.

**Washington.**—Ten steel ships of 58,850 aggregate tonnage were completed and delivered to the Emergency Fleet Corporation durin the past week and fourteen others, some wood and some steel, of 43,000 tons, were launched. On Saturday four wooden ships left the ways, the third time during the present month when four vessels of this type were launched in a single day. The total number of wooden ships launched in May to date is 22.

**Vancouver.**—In obedience to the order of the Metal Trades' Council, the shipyard workers, said by union officials to number nearly ten thousand, quit work in British Columbia shipyards. The purpose of the strike, the union officials announced, is to compel the Imperial Munitions Board to grant a scale of wages equal to that in effect in the United States and a forty-four-hour week. A payroll estimated at from $40,000 to $60,000 a day is cut off.

**Sarnia.**—An order was received by MacKenzie, Milne & Co., from the Canadian Government for 100 life rafts to be used on transports out of Montreal. The rafts are now being manufactured at their new premises near the ferry dock and a number of extra men are employed in the work. The concern is also [illegible] lifeboats for the French Government and Canadian shipbuilding concerns.

**Victoria.**—At a meeting of the metal trades council here it was decided to continue the strike in the shipyards until a satisfactory settlement between the workers and the employers in reached. Leaders of the returned soldiers of the city offered the services of returned men to carry on work in the shipyards of Victoria. They stipulated they were willing to work at the existing rate of wages, and as many of them as were available and qualified for the different trades would be ready to report at the yards on Monday morning. As the yards are to be thrown open on Monday and on all the government work an open shop prevails, these returned soldiers who report for duty will be given employment if they are fitted for the work. Last night armed guards patrolled the assembly plant at Ogden Point, where five ships are having their machinery installed.

## MUNICIPAL

**Halifax.**—At a special meeting of the City Council, it was decided to purchase from Watson, Jack and Company, Ltd., of Montreal, a 900-gallon combined flusher and sprinkler, to be used on the streets of the city, in an endeavor to overcome the dust nuisance.

**Chatham, Ont.**—W. H. Westman, chairman of the Industrial Committee of the Board of Trade, reports that there are one or two buildings available in this city, at low prices, suitable for manufacturing purposes. Mr. Westman says that there is a good opening here for a foundry.

**Dunnville.**—A vote is being taken of the ratepayers on the question of fixing the assessment of the Monarch Knitting Co., Ltd., at $100,000 for a period of ten years. Ground has been broken by this company for a new smoke stack, 150 feet high and 20 feet across the base. The Foundation Co. will do the work.

**Brantford.**—A variety of matters occupied the attention of the Brantford City Council. The monarch Tractor Co., Ltd., received a ten year's fixed assessment of $18,000, exclusive of business assessment, and the Waddell Preserving Co. one of $10,425, subject to their completing improvements now under way.

**Ottawa.**—The "Journal Press says: "A serious situation has arisen in connection with the city's effort to obtain a supply of slab or mill-wood. Practically all the available mill-wood in the Ottawa district has been bought up by private wood dealers, the majority of whom, it is reported, will not sell to the citizens now, but are holding it until it is dry, when it will command a higher price.

As a result of this state of affairs the city is taking upon itself the responsibility of asking the government to institute an order whereby the control of the supply and price of mill-wood will be placed in the hands of the Dominion Fuel Controller.

## PERSONAL

**Ashmore Kennedy,** of Winnipeg, was re-elected assistant grand chief of the Brotherhood of Locomotive Engineers for a six-years' term.

**Capt. Sidney M. Johnson,** late of the 110th Battalion, was appointed as acting city engineer of Stratford during the absence of A. B. Manson on military duty.

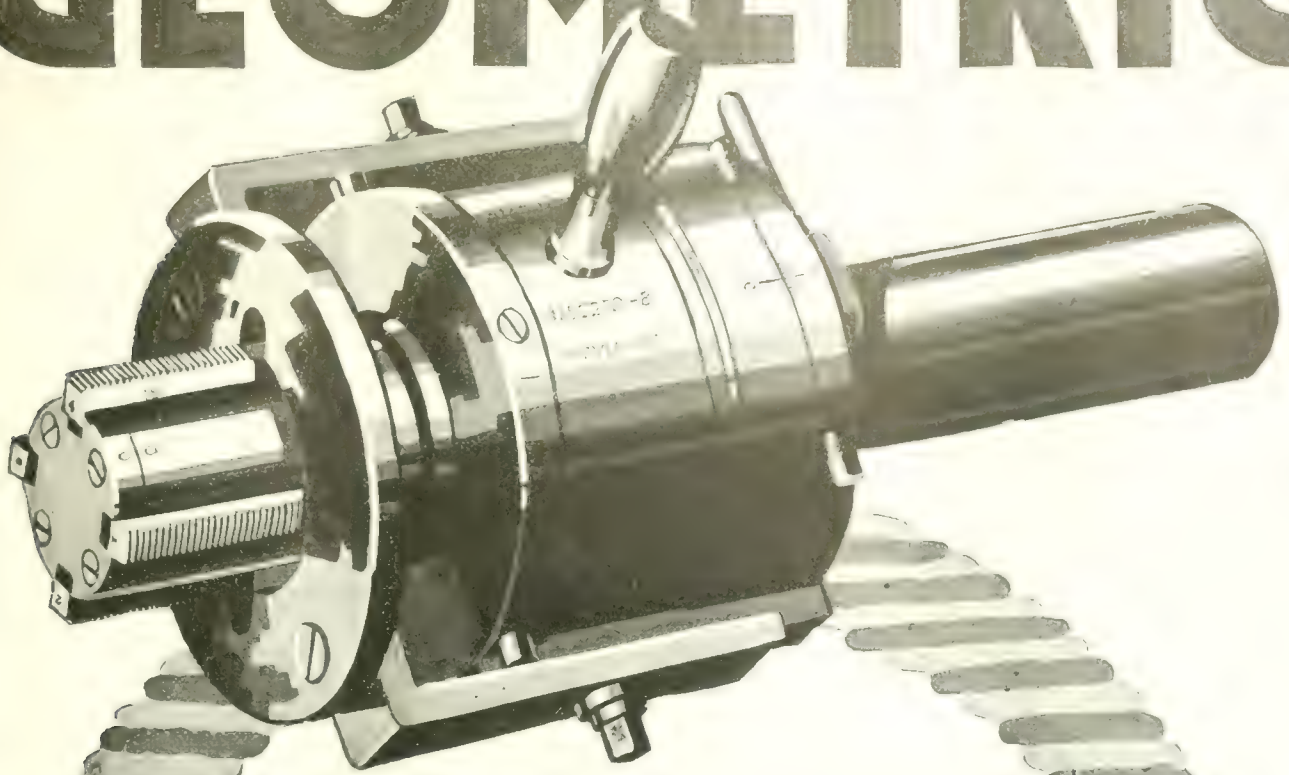
**Chas. Watt,** formerly superintendent of the shell department of the Canada Stove and Foundry Company, has accepted a position as salesman with the Foss Machinery and Supply Co. of Montreal.

**P. O. D. Burke** has been appointed inspector for the New Brunswick board of fire underwriters and will inspect sprinkler equipment and electrical installations throughout the province. He was formerly in the employ of the Nova Scotia Steel Company at Sydney Mines and came to New Brunswick as successor to Simon Skidmore, who was employed by the underwriters to inspect sprinkler installations, and who resigned to take up a position in Montreal on May 1. Mr. Burke, who is an expert electrician, will look after all special risks. Eventually he will inspect electrical wiring in the towns in the province.

**T. A. Summerskill,** one of the best known railway mechanical engineers in Canada passed away after a brief illness on Thursday, at his residence in Westmount.

Mr. Summerskill was born in Great Grimsby, England, and came to Canada when a young boy, entering the service of the Grand Trunk Railway in 1872. After serving his apprenticeship in the mechanical department he spent some years with the company, engaged in the production of a new type of locomotive then being developed. Later he became

# GEOMETRIC



## The Tap Famous For Good Work

Geometric Collapsing Taps share the popularity of Geometric Die Heads. They have the same good reputation for tapping inside threads that the Die Heads have for cutting outside threads. All objections of a solid tap are overcome in the Geometric Collapsing Tap. They are as rigid as solid taps while cutting, but collapse the chasers automatically when the required depth of thread has been cut. Are adaptable to Screw Machine, Turret Lathe or Live Spindle. Made in sizes suited to any diameter above ¾-inch in straight threads or standard pipe thread sizes.

**Write for the Geometric Collapsing Tap Booklet.**

connected with the Canadian Pacific Railway, then nearing completion, first at Carleton Place and then at Westward, organizing the mechanical departments and water supplies at different points along the line. Mr. Summerskill then became mechanical superintendent of the Manitoba and Northwestern, which position he held for a number of years, and again returned to the Grand Trunk as mechanical superintendent of the Central Vermont Railway at St. Albans, Vermont. After spending several years in this capacity he severed his connection with railway work and became a general mechanical expert, and as such gained an enviable reputation in Canada as well as in the United States. At the time of his death Mr. Summerskill was connected in an advisory capacity with the Canadian Car and Foundry Co., Limited.

## RADE GOSSIP

**Will Erect Foundry.**—Darling Bros., of Montreal, have broken ground for their new foundry, which will be located on the site of their old building on Ottawa Street.

**To Make Pumps.**—Peacock Bros., of Montreal, have acquired a two-storey brick building on Delorimer Avenue, and are installing equipment for the manufacture of various types of Weir pumps.

**Wants Market for Fire Bricks.**—A Scotch firm, manufacturing fire bricks, desires to get into touch with Canadian users of these products. (Address British Trade Commissioner in Canada, 367 Beaver Hall Square, Montreal, referring to British Trade Inquiry No. 2989.)

**Gauge glasses, lubricators, etc.**—An English firm of manufacturers wishes to communicate with Canadian importers of gauge glasses and lubricators. (Address British Trade Commissioner in Canada, 367 Beaver Hall Square, Montreal, referring to British Trade Inquiry No. 2990.)

**Can Ship Now.**—Messrs. B. Enushevsky & Son, 536 Queen street E., Toronto, announce that they are now in a position to make prompt shipments on the various sizes of steel and iron shafting, of which they carry a large and miscellaneous stock.

**Increase Capacity.**—The St. Lawrence Welding Co. of Montreal have taken over the adjoining property on Inspector Street, which will treble the capacity of their previous plant. In addition to their regular activities in oxy-acetylene and electric welding, they have recently installed a thermit welding plant.

**Building Addition.**—An addition is being erected to the plant of the Gray Mfg. & Machine Co., at 686 St. Clarens Avenue, Toronto, of two-storey steel and brick construction, 37 ft. x 72 ft., at a cost of $15,000. A travelling crane is being installed and the firm will be better equipped to manufacture their lines of lathes, thread millers, shell blasts, etc. The building is to be finished in five weeks' time.

**Will Wind Up Contracts.**—Having been engaged, since the fire, in a temporory plant in the rear of the destroyed buildings, on finishing up shells rescued from the fire, and also on the unfinished material from the plant of the Western Machinery Company, of Port Arthur, which company assigned the Copp Company expects to finish all work by the end of June, after which there will be no shell manufacturing plant in either Port Arthur or Fort William.

**Big Shell Orders.**—Announcement was made by the Motor Trucks Company, of Brantford, of the acceptance of an order for the manufacture of 9.5 and 4.7 high-explosive shells. The contract approximates an outlay of $7,000,000, and necessitates new buildings and equipment at a cost of $1,000,000. The buildings have to be completed in 45 days The firm will employ 800 men and women on the completion of the contract, the time limit for which has been set for January, 1920. The company is just finishing up a big contract for the manufacture of 4.5 shells.

**Knotty Point Settled.**—A very important judgment and order has been issued by the Dominion Railway Commission, whereby the inter-switching order has been extended to cover team track deliveries on the various railways. The order, which covers the entire Dominion, becomes effective July 1 next. Heretofore deliveries under the order have been confined to industrial and private sidings. The additional charge for the inter-switching service remains, as at present, in so far as the industrial and private sidings are concerned, but an additional charge will be made for service for team track deliveries. The matter has been hanging fire for several years. There has been more or less trouble with respect to the interpretation of the "inter-switching order," but there is no doubt as to the interpretation of the new order, every clause of which is laid out in detail. Provision is also made for the future at all points where inter-switching tracks may be installed.

**Red Tape Abolished.**—An unusually interesting order-in-council was recently passed at Ottawa; interesting in that it eliminates a lot of unnecessary red tape, and does away with an apparent discrimination against the Canadian machinery maker. Since early in November, 1916, all shipbuilders have been granted a drawback of ninety-nine per cent. of the customs' duty allowed on imported materials used in the construction of ships. This worked very well for the shipbuilder, but the man who sold him machinery in Canada could not get a draw-back until the shipbuilder had completed his boat, delivered it, received the money and then made an application

# Almond MICROMETERS

## *Highest Quality Tools*

**Quick Deliveries**

If you want reliable, high quality micrometers specify "Almond." We can suit any requirement and are exceptionally well equipped to make prompt deliveries.

Almond Micrometers are made English measurements 1, 2 and 3-inch by thousands and ten thousands; metric measurements 25-50 and 75 m m by 1 000 m m. With or without Ratchet Stop.

ALMOND MICROMETER HEADS — For attaching to machines and tools where fine adjustments are necessary.

bersome and costly, that the shipbuilder found it far easier to buy machinery direct from the United States and take the Canadian machinery man had, apparently of necessity, to charge the full price, including duty.

## CATALOGUES

**Hydraulic Valves and Fittings.**—A new catalogue of hydraulic valves and fittings has just been issued by the Hydraulic Press Mfg. Co., of Mount Gilead, Ohio. The book is quite elaborate in make up and presents the complete H.P.M. line very attractively. The four general classes of hydraulic valves are clearly illustrated and described. These are operating, check, knock-out and safety. Every standard type of hydraulic fitting is also listed, also accumulator controls, pressure gauges, hydraulic pipes, etc. Many of these hydraulic devices are of improved design and are here published for the first time. Interested parties may obtain copies from the above address.

THE initial flights of the French Government's aerial postal service will be between Marseilles and Nice and Ajaccio, and that there will be daily flights in both directions. Later a service between Paris and London is to be considered.

### MARKET DEVELOPMENTS

Continued from page 580.

bearing on steel supplies and requirements. It is considering the various war requirements, which hitherto have been stated chiefly in terms of the total tonnage required, and the kind of steel it will require to consume each batch of steel and thus it is hoped to arrive at an idea of how much steel per month will be required for the direct war activities. With a study likewise of probable supplies, it will be shown in a measure how much steel will likely be left and it will then be possible to determine how far it will be necessary to go in regulating the distribution of steel, whether it will be necessary to allocate all the remainder to industries that are helpful in winning the war, in the order of their helpfulness.

The steel trade continues to entertain expectations that in the long run there will be enough steel for most of the commercial industries, and certainly for all that can show that they are distinctly helpful in an indirect way to the war work. The jobbers, who were getting somewhat better supplies a month or two ago, have lately been practically shut off, but they are likely to have much better service in the near future, as it is recognized that they have in large part depleted their stocks through furnishing material used in filling war orders, but without getting credit for such steel, by way of priorities for fresh deliveries from the mills.

## DENY REPORT OF TAKING OVER PLANTS

**Steel Output is Increasing Rapidly and Results Are Satisfactory**

Special to CANADIAN MACHINERY.

NEW YORK, May 28th.—As a result mittee of the War Industries Board and representatives of the steel manufacturers held last Monday, practically all shipments of the output of the steel mills have been shipped on government contracts. It had been shown by the Director of Steel Supplies that approximately 2,000,000 tons had been added to the needs of the U. S. and its Allies since April 26th, when Mr. Replogle estimated that war requirements would take up capacity of the steel plants during the last eight months of this year based upon production equal to the average output during first quarter of this year.

In the last two months, as previously noted, output of both pig iron and steel has increased so that to-day the plants are operating at the rate of nearly 44,000,000 tons of ingots, 33,000,000 tons of rolled steel products and 42,000,000 tons of pig iron a year. Upon this basis, the steel companies will produce approximately 22,000,000 tons of rolled steel products from May to December, inclusive.

**The Priority Plan**

The government insists that war needs will absorb the entire output of the plants whatever it may be this year. Steel manufacturers, while accepting the government view that it will need 22,000,000 tons of rolled steel believe that if shipments can be made in definite tonnages on a monthly basis that all the war requirements can be satisfactorily met and still leave a moderate tonnage applicable to commercial consumers' contracts and that deliveries can be extended well into 1919.

Word was received from Washington last Wednesday that an official statement had been made at a war council that the government would take over all of the steel and would regulate the distribution of such tonnages as were not required for war purposes. This statement was interpreted to mean that the government was about to commandeer all of the steel plants, but this was promptly denied by Washington authorities.

**Another Arsenal**

Arrangements are being completed for the construction of another government arsenal to be located at Nicetown, Pa., to be constructed, equipped and operated by the Midvale Steel and Ordnance Co., similar to the Neville Island plant to be constructed by the U. S. Steel Corporation. According to trade estimates $50,000,000 will be expended by the government for construction and equipment and about 30,000 tons of steel will be required. For the two plants, at Neville Island and at Nicetown, it is estimated that at least $30,000,000 will be expended on machinery and this will probably be increased by $20,000,000 before the plants are in full operation.

The constant operation of manufacturing plants at full capacity and at high pressure with extra shifts of labor requires the active purchasing of machine tools for replacements as well as [illegible] the continued expansion of war plants calls for the purchase of new tools in large numbers in the aggregate. The Wright-Martin Aircraft Corp., referred to last week, has already purchased $1,500 000 worth of machinery for its Long Island City plant and it is still in the market, having obtained an order from the government for an unlimited number of airplane motors.

Orders for about 400.000 tons of steel, of the 1.000 000 tons required for the building of railroad cars for the government, have been allocated and the balance of the tonnage is now being distributed. Full requirements cover 925.000 tons of bars, plates and shapes, 23.000.000 tons of bolts, 7 000 tons of rivets and 18.000 kegs of wire nails.

Railroads that are now testing the market for structural steel for bridges and repair shops and for machinery are startled by the heavy increase in the cost of machine tools and consequently purchases may not be made to the full extent contemplated. The Central Railroad of New Jersey is revising its list for 100 tools. The Erie and the New York Central have made moderate purchases. The Baltimore & Ohio is building a locomotive repair shop at Glenwood, Pa., requiring 2,500 tons of steel. Specifications are now being issued for the cranes and other machinery needed.

## OPENING OF NEW ADDITION TO C.M.C.

### Ball and Concert Held by Mutual Benefit Association in Galt Extension

Over three hundred persons were in attendance at the ball given by the C. M. C. Mutual Benefit Society at Galt on May 17, the affair taking place in the new addition to the plant. Guests were present from Preston, Hespeler, Kitchener, Hamilton, Guelph, Brantford and Paris. The new building was handsomely decorated for the occasion and an orchestra of some fifteen pieces provided splendid music for the dancing. Previous to this a choice programme was rendered, the numbers being thoroughly enjoyed and heartily encored. T. H. Watson, president of the C. M. C., was chairman of the evening, and in his introductory remarks said: "So great is our confidence in the future prospects of this splendid city that we have erected this addition which after to-night will be the scene of much activity. One thing that is at present a drawback is the lack of houses for the accommodation of our workmen, the majority of whom stayed by us in the most critical period of our history and to whom I express my heartfelt gratitude, and I hope the day will soon come when every employee can have a home of his own."

HOW to tell a GOOD File by the tang

First, understand what we mean by "good." For an ordinary file may, for a time, do fast work on soft material. A file, to be what we term a **good** file, however, must do fast work on the hardest, the toughest material, and continue to do it long after the teeth of a common file would be worn smooth. A file made of

**Crucible Steel**

is the only file able to retain sharp cutting teeth against hard metal.
Therefore, only a crucible steel file meets our idea of a good file.
There is but one line of files from 3 to 24 inches made absolutely of crucible steel, and they're backed by 50 years of file-making experience. You can tell them by this trade-mark on the tang.

The new addition is up-to-date, bright and well ventilated, with a floor space of 34,798 square feet. It was built by P. H. Secord and Sons at a cost of $50,000.

## DRUMMOND McCALL OPENED NEW OFFICES

### And Improvement Has Also Been Made to the Warehousing Property

The general offices of the Drummond McCall Co., 373 Front Street East, Toronto, were moved this week into the handsome new quarters just completed, immediately in front of their premises. The office fittings, lighting schemes, and general arrangement of the layout are all that could be desired, and will be much more convenient for the carrying on of the business. The old office upstairs, and in the rear of the new one, will still be used for a portion of the work. The new office has a street frontage of about 60 feet and a depth of some forty feet. The exterior is an attractive buff brick design. The same street effect is carried right across the front of the new warehouse, on a frontage of 120 feet, and the whole premises now presents a very attractive appearance.

The warehouse property has a depth of 300 feet, and is fitted with overhead tracks for the lifting and placing of heavy orders. Along the side of the warehouse a large number of concrete pits have been built, to a depth of about six feet. These are used for the purpose of storing tubes, bars, small shapes and sections. In this way a great deal of floor space is conserved, and it is found that the arrangement makes the handling and stock-keeping of this line of goods a much simpler matter.

## EXPORT OF ASBESTOS FROM CANADA TO THE UNITED STATES

THE following procedure in regard to enport of asbestos from Canada to the United States has been agreed to by the Canadian War Trade Board and the United States War Trade Board.

Application for export will be granted by the Canadian War Trade Board on the undertaking to export either the shipment to the Asbestos Trades Bureau or, if shipment is consigned to importer, the bill of lading will be endorsed to the Asbestos Trades Bureau.

Collectors of customs have been notified that a license to export will only be granted when the above procedure is complied with. It is, therefore, not necessary for the exporter to produce United States import license when making application to Canadian War Trade Board for export license.

## TRADE INQUIRIES

THE following inuqiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained from the inquiries' branch of the Department.

399. **Machinery for corrugated sheet steel piling.**—A Natal firm of engineers and merchants requests catalogues from Canadian manufacturers of a piling machine to be used on corrugated sheet steel piling, for retaining walls, bridges, etc., in connection with ferro-concrete works. Prices and details regarding delivery are requested with catalogues.

402. **Calcium carbide.** — A South African firm of importers is prepared to take up the Canadian agency of calcium carbide. This firm has stores in each of the principal centres of South Africa.

406. **Catalogues.**—A Durban wholesale hardware firm requests catalogues and price lists from Canadian manufacturers of hardware of all kinds, tools of all kinds, shovels, stoves, enamelware and other iron and steel products, also particulars from Canadian manufacturers of cart and carriage woodenware and iron and steel ware, axes, springs, handles, paints and varnish and other lines suitable for wholesale hardware stores.

410. **Machinery and machinery supplies.**—A Durban firm, specializing in machinery of all kinds, requests catalogues and price lists from engineering firms, on machinery of all kinds and engineers sup'plies, and in a special way on electrical machinery and material.

## SUBSTITUTES FOR TIN PLATES IN ENGLAND

IN the summer of 1917, owing to the shortage of tin plate, steps were taken to find a substitute for packing army jam. After experiment a cardboard container was evolved for the purpose, and manufacture was commenced on a small scale in August.

The use of the container was gradually extended to other supplies than jam, and manufacture developed till at the present time there is an output of more than 3,000,000 containers weekly.

The bulk of these are of 2-pound size, but a proportion are of 1-pound and 5-pound sizes, the three sizes being used as substitutes for tinned packages.

A further great saving of tin plate is anticipated by the use of a large cardboard box of specially prepared material for packing biscuits and dried vegetables, an order for 200,000 of which has just been placed for experimental packing. The use of this box is expected to save at least 100 tons of steel for every 1,000 tons of bixcuits packed.

**Canadian Trade Commissioner at Yokohama, Japan.**—Word has been received that Mr. A. E. Bryan, B.A., recently appointed Canadian Trade Commissioner at Yokohama, Japan, has arrived at his destination and is now actively engaged in the interests of Canadian trade with Japan. Mr. Bryan may be addressed: P.O. Box 109, Yokohama, Japan. Cable address: "Canadian."

ACCORDING to the "Cabinet Maker," the Germans are now using for aeroplane propellers different kinds of wood laminated together, instead of the hard woods, such as mahogany and walnut, which it is the custom to use in this country. Experiments were made as to the resistant power of the propeller made from these common woods, and it was found that, skilfully compacted together as it was, it was as difficult to break as the hardest of our English woods. It must be remembered that the fierce strain necessarily makes the life of the best propeller a comparatively short one, and there is something to be said for the view that the German woodworker may, after all, have been right in getting all that he required out of very cheap timber.

## Hydro Electric Power For Sale

THE Pembroke Electric Light Company has a surplus of 1,200 to 1,500 H.P. Rates approximate $18.00 per H.P. per annum for twenty-four hour service.

Good labor conditions. Liberal inducements to manufacturers. C.P.R., G.T.R., and C.N.R. connections.

Industries requiring female labor especially desired.

## Lanco Balata Belting

[illegible] one of the most expensive belts in the market.

When the cost of raw materials increased the price of this belt to where it is to-day, we were a little afraid that it would result in a diminution of our sales. We have been very agreeably disappointed, the sales have not dropped off.

There are cheaper belts on the market that will give a good service but not for a year. That is the secret of the steady demand for Lanco Balata Belting. The method by which this belt is made ensures a very strong and long-lived material. The duck is very heavy and is so tightly woven that the only method of using a gum that would hold the plies tightly together, is by impregnating the duck with a solution of gum. This method is used in making Lanco Balata Belting, and when the solvent evaporates it leaves the gum dry, pliable, and with a strength that, as far as we know, has never been equalled by any other gum. The duck is of course stretched while in the solution and until the solvent has evaporated. Balata gum softens at a temperature of 120° F., but under any atmospheric conditions, except those of heat, it will give a length of service that makes its price worth while.

# THE PRODUCTION OF LARGE MARINE FORGINGS

BY A. G. WEBSTER*

**Suitable Equipment Enabled Urgent Work to be Carried Out in Good Shape —Heavy Tonnage and Quick Delivery Requirements Are Features of Marine Products Activity**

ONE of the most interesting industrial developments in Canada since the outbreak of the Great War in 1914 has been the manufacture of marine forgings. With the building of ships on an extensive scale came the demand for material for their construction. It was fortunate therefore that there was a plant in Canada able to undertake this class of work, not only because of the benefits that accrue from having forgings made in the country but also because of the great saving in time owing partly to the fact that the plants in the United States have more work of this character than they can conveniently take care of. To have had to rely on the States for forgings under prevailing conditions would have handicapped the shipbuilders and considerably retarded the rapid construction of merchant vessels.

### Equipped for Heavy Work

A well equipped plant had been operated at Welland, Ont., by the Canada Foundries & Forgings Co., who for some years had produced marine and locomotive forgings, but the former on a comparatively small scale, the demand not having been of the proportions calling for a heavy tonnage output. Despite this it was a matter calling for considerable expense and executive ability to organize the plant and labor, skilled and otherwise, to produce forgings of the kind required, to meet the rigid specifications. It requires skill of a high order to take an ingot of steel weighing 30 tons and reduce it down so that it will machine up clean and true without any undue expenditure of time in machining for removing too much surplus metal. A good and true forging means time saved in machining and consequently lower cost of production.

### Complete Line of Forgings

The Canada Forge Co. manufacture a complete line of marine forgings for both engine and hull, including principally crank shafts and crank ends, line shafts, tail shafts, thrust shafts, rudder frames, stern posts, etc. The steel used in the manufacture of these forgings comes to the plant in the form of ingots or slabs according to the requirements of the work, and is all open hearth basic, of an analysis to meet Lloyd's requirements. It is obtained from firms making the best material, particular attention being paid to this feature in order to ensure uniform results. The ingots from which the larger forgings are made vary from 14 in. to 30 in. diameter, the latter size ingot weighing about 15 tons.

The steel must be free from piping, blow holes, or segregation and carefully selected in regard to chemical analysis. This is the most important factor in the success or failure of forgings to meet the physical specifications prepared by the inspection companies in relation to marine forgings.

### Cutting Off Crop End.

The ingots are shipped to this plant with the crop end. The metal in the bottom end of the ingot is clean and homogenous, so does not need cutting off. The upper or crop end, on the other hand, has to be removed. This is done by first cutting a slot or nick about four inches deep all round the ingot with an oxy-acetylene torch and at a sufficient distance from the end to obtain metal free from piping or

*Associate Editor Canadian Machinery

other flaws. The ingot is lifted up by an overhead travelling crane and allowed to fall, to break the crop end off after nick has been cut. The broken end is then carefully examined for piping and if any defects are found, which occasionally happens, two or three more pieces are cut off on a power saw to remove the metal containing the piping. The removal of the crop end is done either before the first forging operation or afterwards, according to the requirements of the case. In large forgings the crop end is usually left on until the other end has been forged because it serves as a very useful balance weight during the forging operation; apart from this it is immaterial when it is cut off.

After being inspected the selected ingots are then carefully heated to a uniform temperature ranging between 1900 degrees and 2150 degrees Fah. and are forged down to the desired size and shape under a William Todd 500 ton hydraulic press, care being taken to do the finishing work upon the forgings when the temperature of the steel is within the "critical range" this ensues fine grain structure which in turn ensures greater ductility than would otherwise result from finishing at higher temperatures. Another important feature is to select ingots large enough so that the sectional area of the body of the forging shall not exceed one-third the sectional area of the original ingot.

### Forging on Large Press

The large forgings and also some of the smaller ones are forged on a 500-ton hydraulic press. This press, it might be mentioned, was installed some years ago and was therefore in operation before this more recent development in the company's activities. The press is served by an electrically operated overhead travelling crane and also by a hand operated jib crane, while alongside the press are a number of large oil fuel furnaces.

In the case of an ingot that is to be forged with the crop end on, a bar is attached to that end for the use of the men during the forging operation. The bottom or sound end is forged first and after being heated for a sufficient length of time is carried over to the press. The ingot is carried by a steel chain sling suspended from an electrically operated overhead crane.

In making a line or tail shaft forging the end is forged first, leaving sufficient metal for the flange and test piece, the test piece being forged square after another heat. The shaft proper in the initial stages is forged square and afterwards finished off round. As the forging becomes reduced in diameter it lengthens out considerably and has to be supported at the end by a chain from a jib crane, to keep the forging from sagging. After being heated a second time this end of the forging is finished off. The crop end is then cut off by the process already described and the other end of the ingot is forged in the same manner as the first half. The smaller forgings for the most part are made on a steam hammer. The output of the press is about 10 tons per day.

On each forging a prolongation of the same sectional area as that of the body of the forging is left for testing purposes.

### Heat Treating

All marine forgings are heat treated, or annealed, the company having facilities for handling the largest forgings. As a rule the forgings are heated in a furnace and allowed to cool gradually but in some cases they are oil annealed. For this process large oil tanks are installed, each tank having a compressed air system for agitating the oil to equalize the temperature. The oil is cooled by means of cold water which circulates round the outside of the oil tanks..

The forgings having been allowed to cool are now ready for the heat treating furnace, which is of the car type, over fired furnace, using oil fuel and equipped with Tycos base metal, thermo electric, recording pyrometers, which are of inestimable value in affording a means to check temperatures. The manner in which the forgings are placed upon the furnace is a matter of great importance. The charge is raised above the furnace floor with suitable supports and each forging is placed a few inches

ONE OF THE ANNEALING FURNACES SHOWING SHAFT FORGINGS ON FURNACE FLOOR.

apart, so as to enable the hot gases to freely circulate through the entire charge, so as to insure uniform heating.

The chief reasons for heat treating forgings are to relieve internal stresses or strains which may have occured in the forging operations and to develop the dynamic and static strength of the forgings so as to meet physical tests that are required of them. The results in the heat-treating furnace are governed by the following: Rate of heating, temperature, length of soaking, and rate of cooling, as these features vary with the chemical content of each charge. The desired results can only be obtained with an operator of long experience.

### Inspection and Testing

After heat treatment the forgings are ready for inspection by the surveyor or inspector who has been assigned to this duty. All the marine forgings made at this plant have to pass Lloyd's or equally high inspection. The surveyor places the impresion of his private stamp twice on the prolongation of the forgings, the one piece to be used for the bend, the other for the tensil test. The bend test pieces are usually machined to a rectangular section 1 in. wide by ¾-in. thick, with the edges rounded to a radius of 1-16 of an inch. These are required to be bent cold over their thinner section through an angle of 189 degrees without fracture, the internal radius of the bend being not greater than ¼ of an inch. The tensile tests are machined to a standard size, with a diameter of .564 inches, and a gauge length of 2 in.

The test pieces are then gripped between the upper and lower jaws of a testing machine and the total resistance to rupture is measured. Knowing the cross-sectional area of the test pieces and the load required to break them, the strength per square unit may then be determined. The tensile strength is usually given in pounds per spare inch. The elongation is measured in per cent. of the original test section and is determined from the amount of stretch which occurs when the test has been pulled apart by tension.

The unsurpased quality of heat treated forgings manufactured at the Canada Forge Plant is conclusively proven by the ¾ cup and not uncommon full cup silky fractures combined with high elastic limits and large percentages of reduction of area which occur at this static test. The test results having been approved of by the surveyor the forgings are then ready for machining. The company has a large machine shop equipped with modern tools for machining forgings and other work in connection with its business.

## GAS AND WALL TEMPERATURE OF GAS ENGINES

By D. Street.

EXPERTS in Europe have been experimenting on the temperatures occurring in gas engine cylinders, and the experience gained is of great interest to all engineers specializing in this type of power engines. Moreover, it increases our knowledge of the working conditions in gas engine cylinders precisely where it is at present very deficient, and paves the way for further progress. The results obtained apply more or less to all types of combustion engines. For experimental purposes an engine has been found most useful, of which the following are the most essential details:—A small single cylinder, single acting, horizontal, four-cycle engine, having a cylinder seven inches in diameter, with a 15-inch stroke, capable of developing a maximum of twelve indicated horse-power at 240 revolutions per minute. This corresponds to a mean effective piston pressure of 68.5 lbs. per square inch. Ordinary town gas was utilized.

The gas and the wall temperatures are the points about which reliable information is required. The former can be measured by thero-electric couples formed of alloys of rhodium and iridium with platinum, whilst the latter can be measured by mercury thermometers when only average values are required. For more exact results thermocouples are used, in which one element is a plug let into and flush with the wall on the gas side, but drilled hollow, so as to leave a

INTERIOR OF ONE OF THE MACHINE SHOPS DRILLING CONNECTING ROD FOR MARINE ENGINE.

thickness of metal at the couple itself of about one-fiftieth of an inch.

The valves and the pistons are the parts selected for these couples. The wall plug is assumed to represent the skin of the wall metal so far as temperature measurements are concerned. The results obtained have shown that the explosion temperature at the maximum pressure occurs between 3,300 and 4,000 degs. F., depending on the conditions of running, the pressures varying apparently from approximately 236 lbs. to 440 lbs. per square inch. The higher pressures are considerably above those occurring in large gas engines of the double-acting fully water-cooled type. These temperatures were obtained at about three-eighths of an inch from the wall surface, and it may be assumed by prominent experts to range from 4,000 to 4,500 degs. F. It may be assumed that the lower explosion pressure in very large engines will cause somewhat lower temperatures to occur.

For the practical engineer suction temperatures are extremely important, because they serve as a guide to the general level of temperatures throughout the cylinder, and because if they get too high in large engines they limit the power developed by reducing the weight, not the volume of the charge taken in on the suction stroke. It has been the experience of most engineers that a dirty engine develops less power than a clean one, and although this is no doubt sometimes partly due to restriction of the inlet valve passages by tar and other deposit, yet it primarily arises from an increase in the suction gas temperature due to hotter metal in the walls. Moreover, apart from the power developed a high level of metal temperature increases the risks of fractures, and, since it usually indicates the presence of lodgements of carbonaceous or other deposits in the cylinder, it is likely to be accompanied by pre-ignitions, to avoid which the engine load has to be reduced or the engine taken out of service for cleaning.

Experts have worked out the following interesting fluctuations in wall temperature:— With an average mixture and cold jacket the greatest difference of temperature was 143 degs. F. in the centre of the piston head; but when the mixture was richer, yielding a warmer jacket, it was reduced 50 per cent. The cylinder barrel temperature, it has been ascertained, under certain conditions ranges from approximately 120 to 180 degs. F., the piston being mainly cooled by contact with these walls, also to some extent by air. The same experiments are stated to have yielded a piston temperature ranging from 430 to 648 degs. F., and the mean jacket-water temperature was ascertained to be 80 to 94 degs. It may be inferred from these data that should the jacket have too low a temperature the risk of fracture is somewhat increased, as the periodic variations of the temperatures are very considerable.

In the case of engines, when the piston is effectively water-cooled the piston temperature is considerably less. In engines with pistons without water-cooling the heat travels from the centre of the piston face to the wall of the piston; it then passes through the oil film to the barrel of the cylinder and across that to the water jacket. Experts have ascertained that the maximum range of the heat flow to the water jacket approximates to 720 B.t.u. for each square foot per minute; in effect a difference of 65 to 70 degs. F. through the cylinder wall from gas to water. For the Diesel engine, other experts have ascertained the corresponding figure to range from 880 to 900 B.t.u. The study of combustion-engine cooling has been somewhat facilitated by these data. The recognized method has been by sluggish water jackets, but internal cooling has recently been preferred by some experts who have experimented with water jets made to impinge on the metal walls; the resulting steam and hot water is, of course, got rid of in the exhaust.

In two-cycle engines scavenging by air is necessary to obtain the required internal cooling and to get rid of the burnt gases; in four-cycle engines it has its advocate. The system has the advantage of cooling the walls by direct contact where the heat is greatest. It should be added, however, that internal cooling is only available in the intervals between the maximum temperatures, whilst water jackets are continuously effective.

## MECHANICAL ENGINEERS HOLD SPRING MEETING, JUNE 4-7.

The spring meeting of the American Society of Mechanical Engineers will be held this year at Worcester, Mass., June 4 to 7, with headquarters at the Hotel Bancroft. Professional sessions will be held both at the hotel and at the Worcester Polytechnic Institute, and will largely relate to questions with which engineers are now having to deal in connection with the war.

The acquaintanceship session on the evening of June 4 will be followed by professional sessions on June 4 and 5 during which special arrangements have been made for plant visitations by the ladies. June 7 will be occupied with an automobile trip to Camp Devens.

The society points out that the Allies, after three years of bitter fighting, have found that co-operation greatly increases their resistance to the foe. This effect of co-operation is apparent, not only in the front line trenches, but also at supply bases and in every organization supplying material for the front trenches. It also extends through the very fiber of our social organizations. For this reason it is more essential than ever that the engineers should come together for mutual benefit and co-operation. The meeting is planned on this basis, and every member who can do so is urged to attend. Never before has it been so necessary for engineers to get together to pool their knowledge, co-ordinate their work, and secure an interchange of ideas. The following list of papers will be presented at the meeting:

Foundry Cost and Accounting System, W. W Bird.

The Public Interest as the Bed Rock of Professional Practice, Morris L. Cooke.

Moisture Reabsorption of Air-dried Douglas Fir and Hard Pine, and the Effect on the Compressive Strengths, Irving H. Cowdrey.

A High-Speed Air and Gas Washer, Lieut. J. L. Alden.

Investigation of the Uses of Steam in the Canning Industry, Julian C. Smallwood.

Efficiency of Gear Drives, C. M. Allen and F. W. Roys.

Some Economic Aspects of Fire Protection, J. Donald Pryor and Frank V. Sackett.

Self-Adjusting Spring-Thrust Bearing, H. G. Reist.

Air Propulsion, Morgan Brooks.

The Elastic Indentation of Steel Balls Under Pressure, C. A. Briggs, W. C. Chapin, H. G. Heil.

Electric Heating of Molds When Starting or Stopping, F. Hymans.

An Investigation of the Fuel Problem in the Middle West, A. A. Potter.

Oil Fuel in New England Power Plants, H. W. Ballou.

# The Employment of Women in Munition Factories

By Miss O. E. Monkhouse, M.B.E., B.A. (Lond.)

*The following article was read by the author before the Institution of Mechanical Engineers at London, England, last March. In the course of her remarks she referred particularly to the compliment accorded her in being asked to give her views before such a body.*

AT the beginning of the war it was an exceptional thing for women to be employed as general machinists and fitters in engineering shops, but the demand for a greatly increased supply of labor of all kinds for munitions production, and at the same time the necessity for conserving the man-power of the country to the fullest extent, made it necessary for the Government to turn to the largest source of supply of unskilled labor, namely, women. The successful employment of women in engineering works depends not only on the unskilled woman, but in an almost equal degree on the skilled man and the employer.

### The Employer

The successful employer of women labor faces the question of dilution squarely, and recognizes at the outset that the psychology of the woman worker is different from that of the man. Next he fixes on work suitable for his new type of employee, and then determines the quickest and easiest way to train her in the work. He assures himself of the extent to which the men will co-operate, and is always careful to provide suitable shop conditions and plant, etc.

Having made these preliminary arrangements, he realizes the necessity for carefully choosing the right class of labor, and his next step is to appoint a woman of experience to engage and look after the women, and to select as their technical overseer a foreman who he knows is sympathetic with his new venture.

The skilled men have to do the technical training, and have to use all their brains and skill in order to train inexperienced women. They have to sectionalize work, adapt machinery, and simplify operations so as to make it possible to employ women. In their hands is largely the power to oppose and retard all progress by women on skilled work, because at the outset hardly a single woman is in a position to know when obstacles are being placed in her way. She perforce has to rely entirely on their generosity, and her position in engineering shops to-day shows that she has not relied in vain.

On the other hand, it must be remembered that every man does not make a teacher, and that every teacher of men is not necessarily a suitable teacher of women. Thus the unequal success of women in different shops is due in a measure to this cause as well as to antagonism on the part of the men.

### The Unskilled Woman

The successful woman worker in an engineering works has a great deal to learn, because in addition to learning her work she has to acquire correct work habits and face obstacles, both necessary and unnecessary, which are constantly put in the way of her becoming efficient.

There are, however, three grades of unskilled women who must be taken into account:

(1) The educated type.
(2) The domestic type.
(3) The ordinary factory type.

The educated type come with trained brains; they know how to learn and how to apply their knowledge. They probably have mathematical training and can be taught in a very short time how to use a slide-rule, a micrometer, and other gauges. Fine limits present no difficulty to them, and in a sense they may be regarded as already half educated for the better class of engineering work.

The second type, namely, the domestic type, drawn mostly from the daughters of small tradesmen, generally have a good deal of sound common sense, are reliable, and enjoy, and so aim at securing, some position of authority. Such people train quite readily into good charge hands and forewomen.

The factory type are different from either of the other two—they are mainly concerned with making as much money as they can, and preferably on piecework. For the most part they resent being put on to a new operation, because every time they learn anything fresh it means a temporary set-back in wages. It has, therefore, been found best to employ such workers on purely unskilled work of a repetition nature.

But no matter what the type of unskilled women, it must always be borne in mind that their success depends largely on the judgment of the management in selecting a good class of women labor. At the present moment there are, roughly speaking, close on 1,000,000 women employed on the production of munitions of war.

The introduction of all these women into engineering shops meant that a great many difficulties had to be overcome. These may be briefly summarized as follows:

(1) A very large proportion of the women employed not being accustomed to factory life and discipline.

(2) The majority of works managers and foremen not being accustomed to managing women workers.

(3) The shop conditions for the most part planned with a view to the employment of men.

(4) The use of the machinery to which women have hitherto been unaccustomed.

(5) The difficulties of maintaining discipline in a mixed shop and in entirely female shops staffed by women of no previous factory experience.

(6) The long hours.

(7 The question of physical strength.

Many of these difficulties have been overcome by careful selection of suitable work, a careful choice of labor, proper shop organization, conforming to definite welfare standards, installing or adapting plant suitable to women's use, supplying proper training facilities, subdividing skilled work and adapting the hours of employment in accordance with the class of work done.

### How Women Have Reached Their Present Skill

At the stage which women have reached at the present moment in engineering nothing but harm can be done by praising their powers too highly, but there are many individual cases where women have shown very great ability, and have acquired. a knowledge of a certain branch of engineering work in excess of what would have been learnt by an apprentice in the same period under prewar conditions. This state of affairs may be attributed very largely to three causes:—(1) Women have been definitely taught, whereas the apprentices had to pick up their trade. (2) Women have, for the most part, been intensively taught everything in the shop itself under production conditions rather than in the school. (3) The conditions of the time have actuated and spurred on everybody to greater effort from patriotic motives.

There is little doubt that the advantage of getting their training under production conditions has been very largely instrumental in considerably speeding up women's training, and the author would like now to consider some of the methods in use for training women workers.

### Women Trained in Works in a Separate Shop

It is extremely difficult to start women in the same shop with men, unless the latter are in sympathy with the movement, and experience has proved that the only satisfactory way is to start women in a shop by themselves under a sympathetic foreman until they have proved themselves. In illustration of this the author can quote a firm who, up to last April, had no women bench fitters on aircraft work. They have adopted the above plan, and there are now 200 women fitters in the shop controlled by women charge hands, all doing exceedingly well.

Another type of case which should be mentioned is that of firms who cannot believe that women can do anything but purely repetition work, and regard a woman fitter, tool-turner, or tool-setter as an impossibility. It, therefore, is no use telling them that they must up-grade

the firm an expert woman demonstrator. She will first of all do the job herself in the shop to prove its practicability, and she will then continue to assist the firm by training some of their best operators [illegible] them to select others who are [illegible].

There are many firms which, having been assisted in this way, have become some of the most successfully worked shops in the country, not only from the [illegible] of women labor, but of record output as well.

### Other Successful Methods of Training Women Workers

[illegible] to go through at length all the various methods which have had to be adopted in order to make women efficient in the shortest possible time. Government training schools have done much by supplying a nucleus of semi-trained labor to shops desiring either to make a start with women labor or to introduce women on to some new class of work. Just a few large firms have done the ideal thing and set up their own training schools, from which they have a continual flow of semi-trained labor always ready to draw upon.

All consideration of women's work must be accompanied by a careful appreciation of the mental and physical characteristics of women. They have shown great adaptability and natural skill in successfully undertaking work of an entirely new character, but the varying degrees of success points to the necessity for thoroughly understanding their peculiar temperament if the best results are to be obtained.

### Shop Organization

Firms, who with male labor have been thoroughly successful, have failed when forced to employ women labor, thus proving that they did not understand their new employees. Other managers have not recognized their own failings clearly, and numerous cases can be quoted where the want of success of women labor has been traced to defective shop organization. By this term is meant the question of supervision and direction of the work in the factory—work usually performed by foremen and male charge hands. A foreman may be an admirable foreman of men and at the same time an unsuitable foreman for women, apart from the question of his technical ability.

There is no doubt that women do need special managment and it is folly to disregard the human element as some do by asserting that if women are to be employed on men's work they must be treated the same as men. In one sense this is true. Discipline and strict adherence to work should be expected from women just as much as from men. As a rule men are either too lenient or too stern in their treatment of women, or too busy to study their peculiarities, and experience has shown that women should be controlled and organized by their own [illegible] the best results are to be obtained.

### Choice of Labor

There is no doubt that, generally speaking, a woman is a better judge of a woman than a man, and successful firms have realized this and have appointed an experienced woman supervisor, to be responsible for engaging all their women labor. Very recently a case came to the author's notice of a factory where one side of the labor was chosen by a woman and the rest by a man. There was great complaint of the efficiency of the latter, but none of the former. Investigation showed the cause that those women who were "turned down" by the woman supervisor were generally engaged by the man.

In the choice of ordinary operatives, stability of character and suitable physique must be the main considerations, but different characteristics must be taken into account when choosing forewomen and charge-hands. It is most essential that such people should have shop experience, coupled with a certain amount of technical knowledge, and a thorough knowledge of how to manage women, and ability to hold their own in the shop. Women taking up this work must have tact and discretion, and the necessary power to enable them to work in harmony with the shop manager, whose authority should not be interfered with.

Generally speaking, the most successful forewomen and charge-hands have been drawn from the more educated classes. For it must be remembered that women as a whole have been introduced very quickly, in very large numbers, without proper training or proper discipline, and it needs someone with powers of leadership and organization to get the women labor going on a proper footing.

### Welfare

Placing in factories in such large numbers women, many of whom have never been accustomed to factory life or conditions, has also called for special consideration of welfare conditions on the part of the employers. In considering this question, two points of view must be taken in account: (1) Effect of welfare on production; and (2) effect of welfare on the race.

Employers have now for the most part fully realized that to give their women good welfare conditions is a sound business proposition. Without such provision they cannot get a good class of labor. The unwonted heavy muscular effort and constant strain through which they are working makes it essential that their off times should be restful, if good work is to be done after the break.

Good canteen accommodation also is most important, and there have been cases where managers have found that to provide one good meal a day free of cost has been more than repaid to them in output.

But quite apart from the effect of welfare on production is the effect of welfare on the race. From the national point of view this is the most important aspect to consider. For this reason the Health of Munition Workers' Committee was formed, whose special care was to safeguard any deterioration of the race which might perhaps accrue from women being compelled to work in all great industries. They have considered carefully (1) the hours of work; (2) rest periods and provision for meals; (3) sanitary conditions of the factory; (4) physical condition of women workers; (5) questions of management and supervision.

### Hours of Work

With regard to hours of work, experience has shown that a reasonably short shift is the most successful, producing less industrial fatigue as shown by few accidents, better timekeeping, and undiminished capacity of the worker towards the end of the shift so that a better average output is maintained. Another point in favor of shorter hours is the fact that a better class of labor is tempted to join the ranks of munition workers.

The other problems the committee have considered in full detail, and the result of their investigation has shown that the nation is under a definite obligation to consider women's health and comfort in the factories if they are to protect and safeguard their position as the mothers of the race. Experience has shown that wherever there has been proper consideration for women's welfare in factories that there has been not only no decrease in healthy physical development, but a decided increase in mental capacity. It has been an enormous advantage for women to have had this opening into a wider field of skilled and semi-skilled work, and the country has benefited by a tremendous increase of industrial efficiency.

It must be remembered that a woman's work is not ended when she leaves the factory. On her largely depends the life and happiness of the nation in creating and developing a happy healthy family life, and it is her privilege to care for the physical and spiritual welfare of the race. Added industrial efficiency, therefore, at the expense of women fulfilling their primary duties in their homes and to their children cannot result in anything but national disaster, and it is sacred duty of the State to ensure that women are only used as wealth producers in so far as it does not affect the healthy development of the race.

---

EXPERIMENTS in the use of compressed cellulose piping have proved satisfactory in German chemical factories and mining works. It is claimed that the material is absolutely non-porous, is considered lighter than iron, can be worked like wood, and is, consequently, easily moved and repaired. As cellulose is a bad thermal conductor, it requires no particular protection against heat; it also resists chemical influences better than iron. Cellulose tubes are suitable for conducting hot and cold air, and for corrosive gases, which eat into iron conductors very quickly. They are not suitable, however, for steam.

# The Cultivation of Efficiency

## Manufacturers of Plumbing Supplies Co-operate With Employees—Work is Made a Pleasure and Pleasure is Made Profitable — Factory Construction and Individual Comfort Are Features of Conditions

By J. H. MacMillan

LOOK backwards a matter of a very few years and consider the working environment of the factory employee. In ninety-nine cases out of a hundred the employer had no interest in "Jim Smith" or "Mary Jones" other than procuring from them a day's work for a day's wages paid. Sanitation was practically confined to hospitals, and the very word was suggestive of the doctor.

Slowly, but just as surely, the manufacturers have been brought to the realization that, in order to obtain one hundred cents on the dollar paid to the employee that consideration had to be given to the mental and physical condition of the human unit of their organization.

Factory construction was the first item that showed the trend of affairs. Daylight buildings of concrete and steel and a maximum of window space appeared. "Texas" and "Saw-Tooth" roofs put in an appearance. Where a board-walk alley had previously been considered sufficient for a passageway between buildings, roadways of full width, cement paved, sprung into view. Hot and cold air systems for mechanically and automatically washing and freshening the atmosphere were added. Sanitary drinking fountains displaced the germ-laden community drinking cup and dust-laden water barrels. Individual towels, laundered by the company relegated the "wipe" or roller towel to the background, and light, airy toilet rooms took the place of the disreputable foul-odored corners that housed the sanitation facilities (?) of the manufactory of not so long ago. Doctors are employed and paid for by the company to regularly examine those whose duties entail the slightest opportunity for contracting a disorder.

All this, and much more, has taken place to guard the physical welfare of

[illegible] the factory owner even went a [illegible] factor. Based on the fact that a [illegible] is only a small percentage efficient, means of recreation came into being; means to lift the mental power of the human unit away from the daily task in order that the operating functions of that power should be become stagnant by being overfed with the monotony of the day's labor. Club rooms were furnished for the men and women, and from them have grown the spacious rest and recreation buildings that to-day provide the human element of an organization with mental stimulus to render 100 per cent. efficiency at the daily task. All of this is based on the old proverb of "all work and no play," etc.

When you stop to consider that the average employee spends a good deal more time at work than he does at play and at home combined—if you deduct the sleeping hours—it is not any more than fair that his place of employment should be as pleasant as possible.

For many years the various factories and branches of the H. Mueller Mfg. Co., Ltd., manufacturers of water plumbing and gas brass goods, etc., have been carrying out these ideas. To say they are costly is incorrect. The results that accrue more than equalize and justify the cost and upkeep of the institution.

The illustrations presented herewith show, conclusively, the lengths to which the Mueller Company has gone in their Sarnia plant. The plants at Port Huron, Michigan and Decatur, Illinois are equipped likewise. The consensus of the Mueller employees' opinions is the proof conclusive as to the success of welfare work. This work has a moral effect that is alone worth the value of the investment.

The Mueller Company employees have several internal associations, officered and operated by the employees themselves. Foremens' clubs, departmental clubs, etc., an employees' aid society, supported by nominal fees, disburses sick, accident and death benefits. The company itself is back of and supports both morally and monetarily any meritorious, welfare movement that is advanced. Hot tea and coffee is served gratis to each employee at meal times in the recreation building and music is provided and dancing permitted following the meal. Prizes are continually offered for effort along various lines, and co-operation rules in every angle of the big organization.

The writer of this article remembers, some twenty-five years ago, working in a broom factory for one dollar per week. That factory was one of the largest in the business at the time. Every available foot of space was crammed with material and stock at all times. Daylight was at a premium, and fresh air almost unknown. We had a clean-up [illegible] second week for which we didn't get paid—Sunday morning. Anybody caught sweeping the floor around his bench at any other time was fired—with a capital "F." Sometimes the refuse from the broom corn (partially decayed field mice, too, included) was knee high at my bench—I was a "hurl cutter." More than once my stomach revolted and that too, would have to lay. We were positively not allowed to leave our benches except when the whistle blew. Slave-driving methods constituted efficiency of those days. When we contrast conditions such as they were with the modern factory of to-day, we can be excused from wondering how the worker stood his job under the conditions of not so long ago.

There are numerous industries of to-day that have not as yet "seen the light," but they are few and far between. The average factory employee of to-day is the best-cared-for individual in the commercial world—and why not? The human unit is fundamentally necessary to the operation of any industry. We must oil and repair our steeds of steel and fabric; why should be neglect to apply the mental and moral lubricant to our muscle power?

## WEAR IN BIG GUNS

By Mark Meredith.

The wear of big guns has an important influence on the cost of the war, not only on account of the expense of effecting repairs, but because such wear leads to inaccuracy of fire and so increases the amount of ammunition expended to attain a definite objective. If a few thousandths of an inch of steel at the commencement of the rifling of guns, etc., would be prevented from wearing away in so short a time as at present, the reduction in the cost of war, so far as guns, ammunition, transport, etc., are concerned, is almost incalculable.

Differentiation must be made between the damage to the bore near the breach end—which is usually termed "corrosion"—and that near the muzzle, which might on account of its mechanical effect be called "erosion." The causes which produce the first-named class of damage are complex and include the effects of temperature, the form and dimensions of the powder chamber, the chemical and physical qualities of the powder used, the weight of charge and rapidity of fire, the gas escape past the projectile, and the composition and physical properties of the steel used for the inner tubes of the gun. All these matters present many points of interest. Much importance ought to be attached to the evolution of methods for securing the effective sealing of the gas escape immediately after the firing of the charge and as regards the physical properties of the steel used for the inner tube, it would be as well if the heat treatment were subject to the analysis of the steel and the forging effect, and it is really necessary to obtain more effective forging of the portion of the tube forming the bore than is done at present. With regard to the erosion near the muzzle due to frictional wear and metallic fouling, to secure good shooting it is desirable to prevent this by all possible means, such as slightly bellmouthing the bore. Electrolytic methods have removed 15 pounds weight of copper from the bore of an 8-inch gun after firing 100 rounds.

## MACHINE GUNS IN FLANDERS

THERE was a sudden change in the programme at the regular meeting of the Canadian Engineering Institute at their quarters on Mansfield Street, Montreal, due to the demands of military service. Lieut. Philip Bruneau, who had served with the machine-gun corps in Flanders, and recently returned from the front, was to have given an address on "Machine Gun Work in Flanders." He was prevented, for he had been suddenly ordered to leave for the United States for duty as a machine gun instructor.

Lieut. Bruneau's place, however, was ably taken by Lieut. Ashworth, of 2618 St. Urbain Street, who had gone overseas with the 24th Battalion, been transferred to the Machine Guns, been wounded thrice, and so severely dosed with German mustard gas that he had been invalided home, arriving here two weeks ago, with his eyes still suffering from the poison. He gave an interesting talk on the battle scenes he had so recently left, incidentally giving a description of the famous "pillboxes," which he said were the only real German answer to the British tanks.

Lieut. Ashworth cited the great development of machine gun work with the British forces since the first Canadian battalions went over equipped with only two Colt machine guns to a battalion.

There had also been much development in the use of the guns, firing by map and compass after dark, so as to cover ammunition dumps and other places at up to 2,000 yards, which got a lot of the enemy. The main development, said Lieut. Ashworth, had been in barrage fire to protect infantry advances, with a cross, frontal or oblique fire, so that not a man of the enemy could get through. This had been planned in the last big German push against Gen. Gough's division and the guns placed, but, favored by heavy mist, the Germans had been able to get past.

Lieut. Ashworth said the British had taken far more German machine guns than the enemy had captured, and with grim glee recounted how he had personally captured four, with 40,000 rounds of ammunition at Sanctuary Wood, and later used all the ammunition against the Huns with effect.

With the new barrage system for machine guns, Lieut. Ashworth said "going over the top" was not really so terrible, because the fire over their heads made it impossible for the enemy to stay, unless pillboxes were encountered, and these were quite annoying. These he described as cupola topped reinforced concrete structures, the dome only two feet above the ground, loopholed for the sweep of two machine guns, and holding twelve to fourteen men. The walls were eight feet thick, and they could only be destroyed by a direct hit from a heavy high explosive shell, which sometimes would then only overturn them.

# Some Considerations Regarding Modern Plant Organization--6

By M. H. Potter

*The factors which enter into the successful manufacturing business of to-day are interdependent to an ever-increasing degree. Location, type of building, transportation facilities, staff organization and plant equipment are features which require to be considered both singly and as a whole in relation to the particular product to be undertaken. A clear and concise idea of such considerations is necessary before entering any one line of manufacture.*

THE first question in the problem of selling costs is as to whether the sales division shall be charged for goods at the cost to the manufacturing division or at a somewhat larger figure—allowing the manufacturing division to claim a profit. The argument for allowing profit to the manufacturing division is that since greater efficiency will be registered in a larger amount of profit, the inducement to secure better economy will be great. There are, however, but two methods by which the manufacturing division will be allowed a profit. One of these is by allowing as profit an arbitrary percentage on cost. This obviously will not register economies, for the cost is itself the basis of profit. The other of these methods is to allow to the manufacturing division as profit any amount by which it can reduce cost below an arbitrary figure. Under this plan, if there has been a reduction in wages or in the price of raw material, the economy shown by the figure of profit is misrepresented; and, therefore, the plan fails in its specific aim. But, when labor or material has become more expensive, this plan seems to blame the manufacturing management. By this method, moreover, the labor of preserving cost has been largely thrown away, for it assumes as cost for selling purposes a figure that bears no relation to the books. The only possible method of measuring comparative economy is by comparing actual costs in different years and allowing for difference in effective wages and raw materials. This is comparative cost register and the ordinary cost books make this possible. Since such comparison is possible directly from the books, the effort to find a measure of economy in the profits of the manufacturing division is mere wasted energy, and sometimes worse than that, for it may misrepresent the facts. Finally, to handicap the sales division by charging it arbitrary prices is hardly fair when the selling department is in competition with other houses where this is not the practice. The conclusion is that the selling division should be charged for all goods at exact cost to the manufacturing division.

This general rule, however, is open to one notable exception, in the case of manufacturers who do not really manufacture, but have the goods made up on the outside. Some so-called manufacturers do not want to maintain a department devoted to making their products. They accordingly have their material assembled and give some other concern the manufacturing profit.

### Why Selling Cost Must Be Separated

The science of cost is intimately related to the department of sales, but complete separation between producing and selling expenditures is essential. It is absolutely necessary to know first what it costs to produce goods ready for sale, and second, what it costs to market them; since a factory manager may manufacture goods at a cost of production in every way favorable to most successful competition, and yet the business as a whole may not be profitable owing to the excessive selling expenditures. A separation of costs places responsibilities for two entirely different functions, and any changes in either manufacturing or selling conditions are quickly noted.

The principal elements of selling costs may be stated as follows:

**1. Sales Department Space Cost**

This will be determined by the ratio which the space occupied by the department bears to the entire space cost of the establishment; the percentage thus obtained will be calculated on such items as interest, taxes, depreciation, repairs and insurance on the property used by this division.

**2. Light, Heat, and Power**

A meter installed in the department will show the amount of gas or electricity consumed for lighting purposes; heating cost is charged in proportion to cubic occupancy; power, which in this instance might be for the passenger elevator serving many departments, could be distributed on a basis of the number of passengers carried.

**3. Accruals or Accumulated Stock**

Many large establishments are obliged in the dull seasons to accumulate stock ready for the demand of the active seasons. We have, therefore, interest depreciation, and taxes to figure on this accumulated stock. This is not exactly manufacturing cost, for the manufacturing division can not always make goods at the variable rate of the demand of the seasons. It must produce them when it can. It is, however, the task of the selling division to keep goods moving as rapidly as possible, and to offer such inducements as may be worth while to get them out of the warehouse in the dull season. The most effective stimulus to the selling division for keeping the warehouse clear is to charge this division with the cost of accumulating the stored stock. Though this may sometimes seem a hardship, it is unavoidable. For charging to manufacturing would to some extent nullify the careful cost-keeping, especially in the important mat-

should accommodate itself to the varying task of accommodation shall be laid upon the selling division. Whatever cost of this sort is incurred, however, seems properly to belong to the selling division.

#### 4. Office Expenses.

This comprehends the outlay necessary for the maintenance of an office concerning itself solely with the distribution of the product, and includes such items as salaries of selling officers and assistants, printing and stationery, postage, telephone and telegrams. Although the total expense is periodically carried into selling costs for distribution, yet to attain the highest state of efficiency a system of costs should be maintained within the office. The relative capability of each stenographer, for instance, may be deducted from a weekly summary, similar to that shown in Form 1.

For this summary when properly filled out, the manager can determine the total and average cost of letters written weekly, and by comparing the results with former figures he is enabled to set a standard. The fact that letters vary in length is not an obstacle, because in the long run the average length of letters will be about the same for all. The mailing clerks should count each stenographer's mail and initial her daily report, from which the above-mentioned weekly summary is prepared. Similarly the work of each employee of the office may be recorded, bill, mail, and filing clerks noting the daily total of papers officially treated by them; bookkeepers recording the number of daily postings, etc. These daily figures are summarized in the weekly reports to the manager. Where this plan has been tried the results have been very satisfactory, and it has resulted in a sort of friendly competition and endeavor to exceed previous records. The matter of office expense has been treated here only with reference to the selling department and the cost system mentioned is merely suggestive. In a business where the main expenses are represented by office outlays, the value of comprehensive cost keeping is obvious.

#### 5. Salesmen's Commissions, Salaries, and Expenses

These items constitute a considerable part of the expense of selling. Detailed expense accounts should be mailed weekly to the home office by the salesmen. Blanks arranged with columns for constantly recurring items should be provided for this purpose, see Form 2.

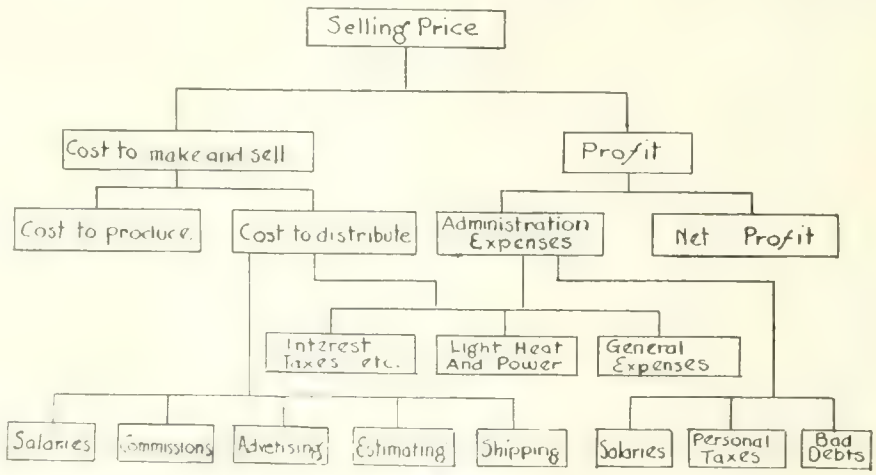
It is usual to open an account with each salesman, and to maintain a careful record of the sales in his territory. The records should show also the ratio of sales expense to each dollar of product distributed, and the relative worth of each salesman and the territory traversed by him.

#### 6. Advertising Outlay

The disposition of this factor requires a knowledge of the circumstances under which the expenditure is incurred. It is at one time an investment and at another an expense. For example, several thousand catalogues may be printed for a concern; these should be carried as an inventory item to be charged in proportionate amounts, as distributed, to expense. Again, in order to place itself prominently before the public, a concern may spend during its first year a large sum for advertising, the benefits of which may not immediately accrue, but which item is nevertheless a factor in the future sales; it would be manifestly unfair therefore to charge the entire amount against the first year's business. It is worth while to note, also, that some advertising costs may not be exhausted in the year of occurrence. An advertising campaign may have a duration of several months or years and at its close a large item of recourse may remain in a form similar to goodwill, in the sale of a business this would have to be acknowledged. In charging off advertising expense, therefore, a medium ground is advisable. A certain percentage of general advertising is an expense and chargeable as such; the remainder goes towards the purchase of good-will, an asset of the business.

#### 7. Cost of Estimating

A selling cost likely to be overlooked is that of the estimating department. In some businesses considerable money is expended in working out specifications and submitting proposals which do not result in sale; this is as much a selling cost as the travelling salesman's expense, and such items should be kept in an account by themselves and later charged in total to selling costs; when a sale is effected the expense connected with the preparation of the plans and specifications is charged against the individual job. The conditions above apply to cases where the proposals in question are for special work, and can not be used again. If, however, the estimate and drawings are to be utilized for future work, they should be considered a part of plant equipment and are properly chargeable to this account.



FORM 3 SUMMARY.

#### 8. Shipping Department Expense

Under this head would be charged

such items as wages of the shipping clerk and assistants, all shipping materials, and any other expenditures incident to the preparation of the goods for delivery.

### 9. Proportion of Administration Expenses

This represents a charge for supervision, and, as each administrative officer should keep a record showing the disposition of his time, the amount chargeable to each department is readily ascertained.

### Apportionment of Selling Cost

Some selling expenses may, however, apply more strictly to one item than to another. For example, if any article ceases to be advertised, yet continues to sell on its reputation, the advertising expense charged to its cost should be slight. If, again, a few articles are placed upon exhibition, the cost of the exhibition should be charged chiefly to the particular article shown; in the latter case, however, the entire cost should not be borne by the articles in question, as the publicity gained from the exhibition will probably cause a demand for other products of the firm. In the final distribution of selling expenses certain costs will therefore be assigned to particular classes of sales, and the remaining selling costs will be distributed over all classes on a percentage basis, which is obtained by dividing the total general selling cost by the total manufacturing cost. This percentage is then distributed [illegible] of production on a basis of their manufacturing cost which has been previously determined.

A distribution sheet should be maintained to show the ratio of the percentage, the expense each department bears to the entire expense, and from this record the manager can determine whether the selling prices are profitable or not. For instance, if the distribution sheet shows that it costs about 12 per cent. of the selling price to dispose of the goods and at that rate a fair profit is possible, the business will be on a safe basis as long as that rate is maintained, but should a period of depression set in, or sales fall off in anything like a permanent manner, the selling cost percentage will immediately increase. It is in enabling the management to reduce expenses without affecting the efficiency of the various departments that the distribution sheet is valuable.

The percentage can be applied to any individual item after it has been manufactured; for example, the cost of raw material might be 60 cents, productive labor 95 cents, and manufacturing or indirect expense 95 cents, thus making the total cost of production $2.50. Assume the selling cost of 12 per cent. of the sales price which shall be stated at $4.00. If the selling expense of 48 cents be added to the cost of production, i.e., $2.50, the cost of the article sold reaches $2.98, leaving a trading profit of $1.02, from which must be deducted its proportion of administration expense in order to arrive at the net gain of the transaction.

### Administration Expenses

While the manufacturing and selling divisions are engaged in working out their problems it remains for another department to control both, finance the establishment, and keep in touch with business conditions generally. These are the functions of the administrative department. Many of the expenses which it incurs may be traced to some particular process or department, and these are accordingly distributed and duly calculated in the producing or selling costs; the remainder, which are general in character, must be considered when the net profit on sales is calculated. Among the latter are:

1. Proportion of interest, taxes, depreciation, repairs, and insurance on the property used. This cost, however, can be made selective.

2. Light, heat, and power consumed by this department.

3. Taxes on personalty, which represent the annual levy to the capital invested; they do not include taxes on real property, which are already included in Item No. 1.

4. Officers' salaries: the balance remaining after all time spent in super[illegible] departments.

5. General office expenses, including: office salaries, printing and stationery, [illegible] miscellaneous items.

6. Bad debts. This would seem to be a just charge against the administrative department because all orders are filled by the selling division only after the former has passed upon them, it would seem unfair therefore to charge any loss for uncollected accounts to the selling division.

Summary. We have finally, then, for every article manufactured a certain specified list of items which enter into its selling cost. They may be summarized as shown in Form 3. An analysis of these items gives that which the business man wishes to know, namely, the cost of manufacturing and selling, the selling price, and the profit.

## INTENSIVE FUEL CONSERVATION CAMPAIGN IN IOWA

ANNOUNCEMENT was made recently by Royal H. Holbrook, state deputy of National Association of Stationary Engineers of Iowa, that a movement to effect fuel conservation throughout the state had been commenced by the association.

Practical methods are being followed and qualified advisers will be sent to any commmunity, large or small, which makes a request. A few of the most important test instruments will be taken along, such as a Bacharach pocket $CO_2$ machine, a draft gauge, a thermometer for about 800 deg., some charts for firing illustrations, and lantern slides, so that the engineers and firemen may have one meeting and the general public another. An intensive press campaign will be put on in all state papers, and a still more intensive plan in the city or community visited. The intention is to visit every plant, be it boiler or furnace that sends in a call. The list is usually made in advance by the secretary of the commercial club, which is in most cases responsible for the local expenses. In every city where there is an N. A. S. E., they will arrange for a campaign meeting in case it is not on the regular meeting-night programme.

## ANNUAL MEETING OF THE ONTARIO SECTION A.S.M.E.

THE annual meeting of the Ontario Section of the American Society of Mechanical Engineers was held at the Engineers' Club, Toronto, on Monday evening, May 27th.

The technical paper for the evening was presented by Mr. J. H. Billings on "Strength of cast iron in bending as affected by variations in cross sections." Following this was a very interesting and stimulating talk by Mr. Calvin Rice, general secretary, who had arranged to stop over in Toronto on his way back to New rork from a visit to some of the society's branches in the Middle Western States.

The results of election of officers for [illegible] follows: Chairman, Professor R. W. Angus, of the University of Toronto; secretary, C. B. Hamilton, of Hamilton [illegible] of executive, Mr. James Milne, City Hall; Mr. J. H. Billings, University of Toronto; Mr. T. B. Ahara, Canadian Fairbanks-Morse Co.

A NORWEGIAN engineer has devised an ingenious method of reducing the cost of paper manufacture by utilizing the residue from the mills, which produces a fuel to run the plant. The paper pulp obtained from wood constitutes only 45 per cent. of the wood, and the residual 55 per cent. has hitherto been found useful chiefly for the wood alcohol and acetic acid obtained from it by distillation. This engineer has recently patented and perfected a new process by which the residue furnishes a fuel in the form of a powdered coal, or charcoal, which evolves great heat in commbustion. The first plants have been erected at Greaker, on the Christiana fojrd, and it is estimated that they will shortly be able to yield an annual output of 6,000 tons of this new fuel. This will suffice to supply all the cellulose plants in Greaker with an inexpensive fuel, and at the same time it rids them of a burdensome encumbrance. Since the total production of paper pulp in Norway is estimated at 1,000,000 tons yearly, doubtless other plants throughout the country will soon be similarly equipped.—M.L.

# Using Stellite in Modern Shops: Applications and Devices

## Alloy of Semi-rare Metals Increases Production and Reduces Costs — Increasing Use of Metal Promotes Development of Accessories and Methods of Application

By W. F. Sutherland *

THE stimulus given to alloy research in the past few years has resulted in the discovery of many new alloys of great intrinsic value in the arts and sciences and many metals heretofore recognized only as laboratory curiosities are now an essential part of metallurgical industries.

Stellite, an alloy composed of cobalt chromium and tungsten, has been of great service in the quantity production

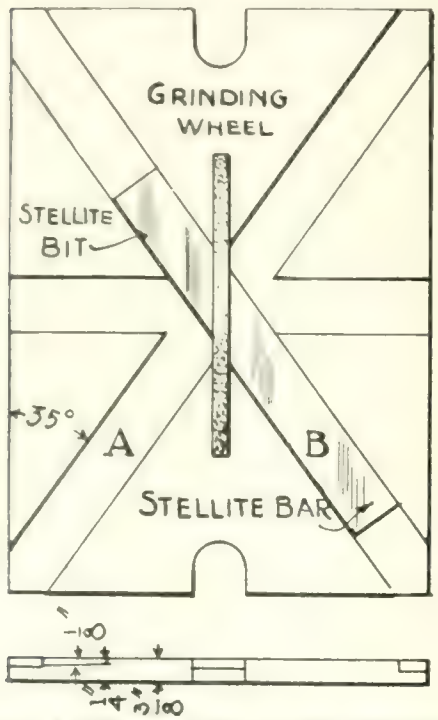


FIG. 1. FIXTURE USED IN THE NICKING OF STELLITE

of munitions and the present article deals with some of the uses to which it may be put.

### Grades and Physical Properties

The properties of stellite vary with the percentages of constituent metals employed and to so great an extent is this true that alloys can be made varying in hardness from that of untempered steel to the quartz crystal.

Three grades are available for machine shop use, each grade being adapted to certain operations and materials; No. 1 for machinery steel up to 30 point carbon, No. 2 for steel up to 100 point carbon and cast iron of moderate hardness, and No. 3 adapted for hard bronze and either hard or soft cast iron. No. 1 and 2 grades take the same shape and tool overhang as high speed steel while No. 3 requires as much heel as possible and the shape is governed by the class of work performed.

Since extreme hardness is an inherent quality of stellite and since it is impossible to forge or anneal it, all shapes must be cast in approximately the final form and finished by grinding.

The cutting of the stellite bars into the proper lengths is accomplished by nicking with a hot saw or by grinding a nick in both faces. Fig. 1 shows a jig by which the bars may be quickly nicked at right angles or on a 35 degree bevel. The bar is first placed in slot A, nicked to a proper depth and then put in slot B. When broken the fracture will follow these nicks and little grinding need be done to finish the tool.

### Typical Lathe Tools

Several types of lathe tools illustrating English practice are shown in Fig. 2. These are made by milling out the machine steel tool shank and welding the bits in place. As the alloy is hardest on the skin the shank is milled out on an angle so as to give the correct top rake without grinding. The different operations in the making of this tool are shown in Fig. 2, A, B, and C. Instead of milling the shank at an angle a special shape may be employed as shown in Fig. 2 D. The slot in all cases should be milled slightly smaller than the bit so as to allow for accurate fitting by grinding.

Fig. 2 F shows an open step tool which is used when a large depth of cut is required.

Welded tools are generally made by welding a tip of stellite to a carbon steel shank, no end milling as described above being done and in this connection it may be remarked that a comparatively thin piece of metal will suffice.

In Fig. 3 and 4 are shown two types of tool made in this manner. Fig. 3 shows a square bit tool deeply notched for the stellite. This construction has the serious disadvantage of weakening the shank very materially as the weld between the stellite and shank is not capable of withstanding the tension stresses developed above the neutral axis of the tool. Fig. 4 shows a more preferable construction. Here the bit is much thinner and is purchased in the wedge form. This obviates the grinding of the top face for side rake and preserves the extremely hard skin; as will be seen the shank is very much stronger.

### Brazing and Welding

Stellite may be readily brazed or welded to steel. In brazing, after the bit is accurately fitted to the shank it should be nicked with a grinding wheel to allow the brazing compound to take a firm grip. The shank should then be

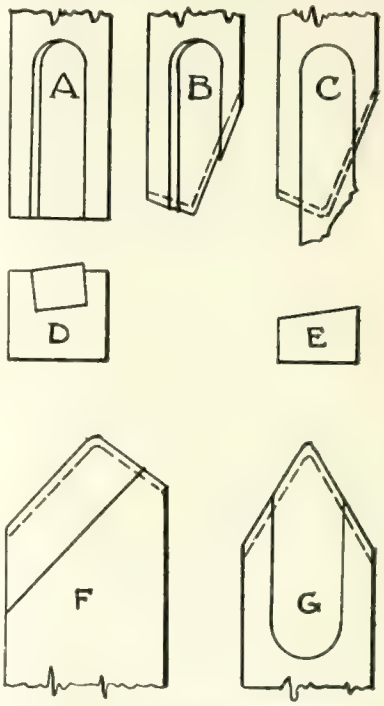

FIG. 2.—VARIOUS FORMS OF WELDED TOOLS, English Practice

well heated, brushed and a thin layer of brazing compound put in the slot. The stellite is placed in position with a piece of brazing compound or spelter of ample size on top.

The tool is then heated until the brazing compound has run well into the joints when it is then quickly drawn and

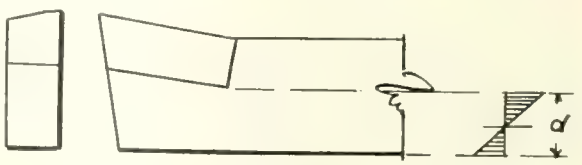

FIG. 3.—WELDED TOOL.

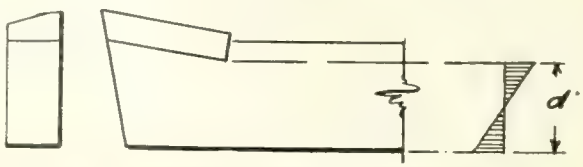

FIG. 4.—ANOTHER FORM OF WELDED TOOL.

the stellite lightly tapped with a hammer to spread the compound evenly.

In welding, both the oxy-acetylene or electric arc may be used. Stellite may be welded to any metal such as iron or steel and no special precautions need be observed beyond the advisability of keeping the stellite from alloying with iron, as far as possible, as iron when alloyed reduces the cutting qualities very materially.

Electric butt welding is difficult on account of the differences in the melting points and resistances of the two materials. The wattage converted into heat in the passage of an electric current through any conductor is measured by the following well-known equation, $W = I^2 R$

where W = watts lost
I = amperes
R = resistance in ohms.

The current flowing through the two objects being welded is of course the same, and therefore the heat resulting will vary directly as the resistance of the two materials.

Stellite has a resistance of between 600 and 700 ohms per mil foot while iron has only a resistance of 63 ohms per mil foot. It is readily seen that the heating of the stellite will be accomplished very much more rapidly than that of the iron since the heat absorbed is about ten times greater. The stellite would probably melt before the iron became red and hot.

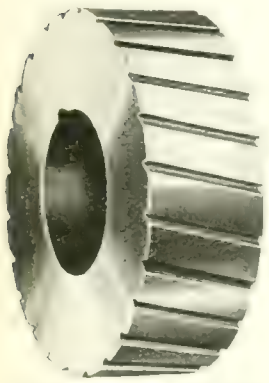

FIG. 5. CUTTER GROUND DOWN.

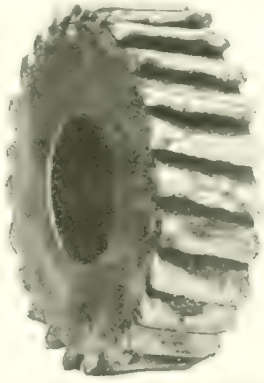

FIG. 6. STELLITE TIPS WELDED ON

FIG. 7. CUTTER RE-GROUND.

The following table is of interest, in giving the electrical characteristics of this alloy:

TABLE SHOWING COMPARATIVE ELECTRICAL PROPERTIES OF COPPER AND STELLITE.

| Property | Copper | Stellite No. 1 | Stellite No. |
|---|---|---|---|
| Specific conductance in mhos per inch cube | 626,000 | [illegible] | [illegible] |
| Specific resistance in michrohms per inch cube | 1.594 | 402.5 | 478.0 |
| Relative conductance | 100% | .0396% | .033% |
| Resistance in ohms per mil foot..... | 10.4 | 603 | 732 |

The electric arc method of welding stellite is quite satisfactory as is also the oxy-acetylene flame.

### Some Applications of Welding

Mention may be made of some of the uses to which alloy is being put in machine and munition shops. By taking a welding rod of stellite and with the oxy-acetylene flame building up a tip on the ordinary carbon twist drill, a twist drill results which gives unequalled service after being ground and sharpened. This process may be repeated any number of times and the combination of tough carbon steel or high-speed steel body and the extremely hard cutting edge of stellite has advantages readily understood.

A somewhat similar method is frequently used for the remaking of a carbon steel milling cutter. The worn down cutter is first ground somewhat as shown in Fig. 5 and a new stellite tip is built up on each tooth as in Fig. 6 after which the tood is reground and sharpened as in Fig. 7.

The special stellite holder shown in Fig. 8 and 9 has been designed to take advantage of the hard skin on the bit casting. This skin is even harder and more resistant to wear than the body of the metal. As will be seen the skin is presented to the work where the rubbing takes place. In this holder the stellite is easily adjusted and can be ground with any cutting rake desired.

A unique tool which has found considerable favor in the finish turning of various sizes of shells is shown in Fig. 10. As will be seen the stellite cutting bit is cylindrical with a hole through the centre. In sharpening, the bit is ground off flat and a conical wheel is then used to form the bevel, the cored hole permitting this to be done with a minimum amount of labor. When one portion of the edge is worn it suffices to turn the bit in the holder slightly until a new cutting edge is presented.

Stellite is adapted to the making of reamers and formed cutters of various kinds and shapes. Formed cutters up to ½-in. face are generally made solid; from ½-in. to ¾-in. face with welded blades and from ¾-in. up with inserted teeth. The solid cutters can be reground until the diameter is too small for further use. The inserted tooth cutter used in the larger sizes like all inserted tooth cutters permits the removal of any or all of the blades without the discarding of the whole cutter.

FIG. 9. DIAMOND SHAPE BIT HOLDER.

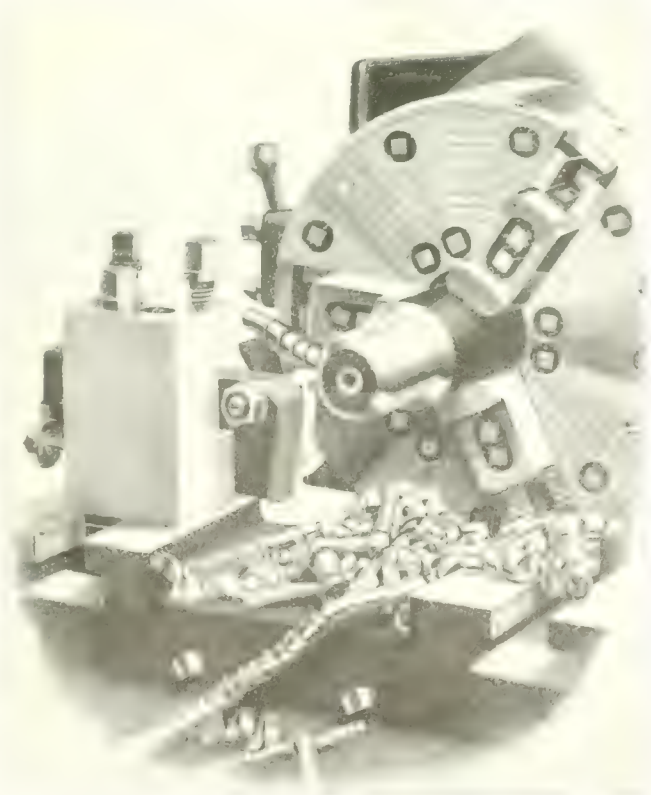

FIG. 8.—STELLITE HOLDER IN USE.

## CUTTING COAL COSTS

has been cheap and obtainable in abundance; cheap coal and cheap labor sometimes made it apparently economical in dollars and cents to install and run an inefficient plant.

Coal has now become expensive. It is hard to obtain. Efficiency in its use and avoidance of waste have become of first importance, since without power other materials cannot be utilized.

These conditions make it imperative for every owner or manager of a power plant to examine into the cost of the power his establishment uses, the economy with which it is generated and applied, and the increase in efficiency that is possible. Some of the steps that an owner or manager should take are:

Find the nearest source of coal that will meet the requirements, even if it does take a little more trouble to use it; the tax on the transportation system will thus be reduced so far as haulage by rail is shortened; coal is mined in twenty-six states, and these states extend practically across the continent and from the northern to the southern borders.

Give to the power plant and its personnel recognition and encouragement such as is due an expert and important department, thus getting new effort and attention to offset the extra attention and care needed with coal inferior in grade and preparation to the coal formerly available.

Seek to increase skill and proficiency in the men who handle the coal; a fireman at a hand-fired boiler shovels three to ten tons of coal a day—as great a value in material as many skilled men in other departments.

Put the fuel-using equipment into as perfect condition as possible; provide at hand-fired plants an ample firing floor with a good surface together with a smooth bottomed coal car if it can be used; eliminate leaks in the boiler setting, see that fire-doors fit properly, replace defective grate bars, make sure that smoke connections are clean and tight; if mechanical stokers are used, see that they are in good repair and that directions for using them are being followed; in general, make the plant and the fire-room of such character that an efficient man will stay on the job.

Install simple and convenient means by which the fire-room forces may see results; scales for weighing fuel and ash, meters for measuring water fed to the boiler, and devices for determining the quality of flue gases, the draft over the fire, etc., can be made to interest the men in the fireroom and show the actual results of efforts to economize; one convenient means for operating the flue damper must be installed.

Endeavor to run boilers in service at their capacity; if efficiency is increased, one or more boilers in a battery may be dropped.

Provide water that is free from scale by using, when necessary, water-testing devices if the plant is large and special feed-water heaters in small plants.

Reduce loss of heat after it is generated; see that that boiler surfaces and steam pipes are properly covered; the simplest and most inexpensive covering will reduce loss by 80 per cent.; in the engine room cut out useless steam lines, have valve properly set, reduce the small auxiliary pumps, etc., to a minimum, provide the repairs the engineer has been asking.

Obtain expert advice; good steam engineers are familiar with well-tried ways of reducing both consumption of coal and consumption of heat; their advice should be obtained in all practical cases; this is not a time for radical innovations but for utilizing tried experience.

One pound of coal per hour has yielded a horsepower per hour. That is the record of present possibility. It cannot by any manner of means be attained by every plant. But the fact that at present the average attainment throughout the country is but one-third or one-fourth of this record is indicative of the possible savings that can be made if the care and attention which the power plant deserves are actually given to it.

The foregoing items are part of Bulletin No. 2, issued by the committee on coal conservation of the Chamber of Commerce of the United States to owners and managers of power plants.

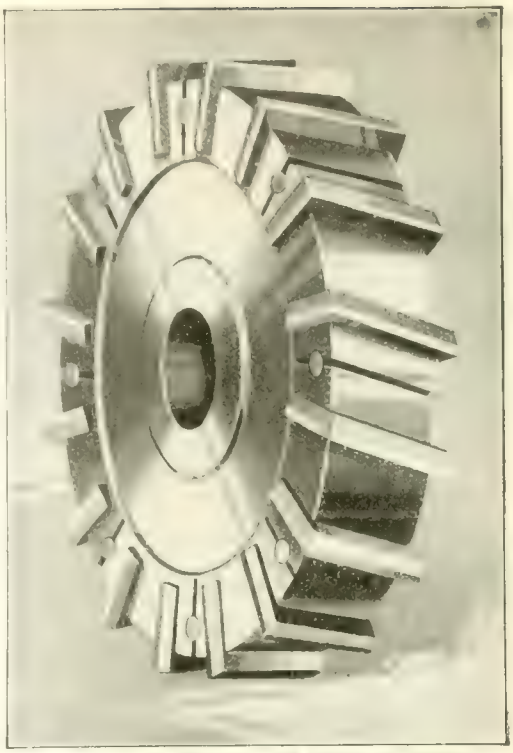

FIG 11. INSERTED TOOTH MILLING CUTTER

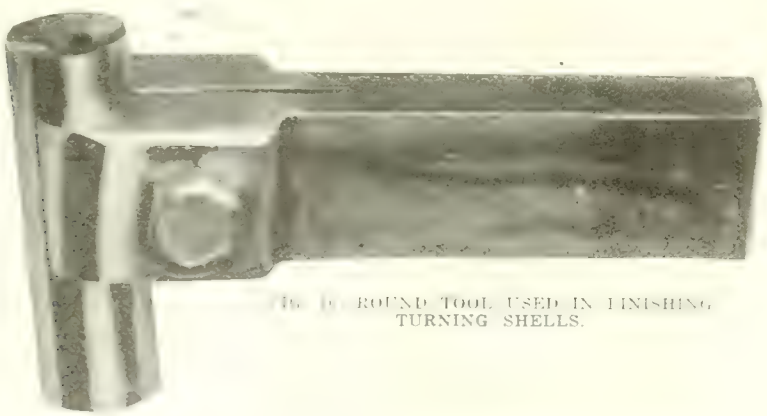

FIG 12. ROUND TOOL USED IN FINISHING TURNING SHELLS.

THE asbestos deposits of Rhodesia are being developed steadily. The production in 1914 amounted to 487 tons, valued at £8,612, whereas in 1915 it increased to 2,010 tons, valued at £32,190. During the first three months of 1916 the production was 914 tons, valued at £14,621. This field is situated in Victoria township, in the Mashatee district, Southern Rhodesia. The asbestos, unlike the Cape mineral, is a chrysolite of excellent quality. According to the returns made to the Department of Mines of the Union the production of asbestos of South Africa in 1915 totaled 2,138 tons, valued at £35,899. On the other hand, the export figures from that country show that 3,034 tons were shipped during that year.—"The Engineer."

ONTARIO is estimated to be now supplying 80 per cent. of the total world's production of nickel, which is now six times as great as in 1900. The richest nickel deposits so far discovered are those at Sudbury. The island of New Caledonia in the South Pacific, formerly yielded 65 per cent. of the total output.

PLATINUM is first recorded in Russia in the year 1821, when it was distinguished in the working of alluvial gold in the Ural mountains. Its value was not appreciated then, hence the discovery attracted little attention. Previous to this it had already been discovered in Colombia, South America.

# Standardization as Applied to the Gear Cutting Industry

By B. F. Waterman *

*In an address on the following page [illegible] of the Society [illegible] Spring meeting, April 18-20, Mr. Waterman outlined standardization as it pertains to industrial activities [illegible] organizations representing the various industries. He referred specifically to the engineering and electrical bodies and pointed out the valuable results arising out of their work.*

THIS association has considered it advisable for the advancement of the gear industry to appoint, as one of its standing committees, a "General Standardization Committee," together with a number of sub-committees, to consider and develop from the mass of data which now exists in various forms, standards for use in this industry, and which will be of value to all who may have to do with gears, either as manufacturers or as users.

In considering this subject, as applied to the various branches of the gear industry, we will first consider it in a general way, and later as applied to each division as represented by the sub-committees.

### Daily Problems

How many times in the course of our daily work do we have a problem to solve, the solution of which cannot be based on scientific data, for there may be none at hand, but must be based on our past experience, which may not fill the need of the moment, a good imagination, if we have one, and a guess? It is, at this time, that a standard method of procedure, based on the same similar data, would be desirable, and if we were called upon to outline such a one, we might do so; but then it would probably be applicable to the conditions of our recent problem only, and would not fit into the general scheme of things.

For instance, suppose we were called upon to furnish a pair of worm gears to give a certain reduction at a given speed to transmit a given horse-power continuously for ten hours without undue heating. How would you go about it? How would your associates go about it? This is nothing more, by the way, than a motor problem which has already been standardized.

It is possible that if a customer was to ask for proposals from every member of this association for a pair of spur gears to transmit a given horse-power between the motor and machine, he would find no two alike, with the result that he would probably take that pair offered by the one he thought knew the most about a problem of this kind, or he would take the smallest pair, as they would be the cheapest; but in any case he would not have any assurance the design he did choose was better than many of the others.

Why this difference? We would answer by saying that no two engineers will use the same strength formula, or, if they do, and [illegible] the same material, the values given the same factors will be different, or one engineer will use additional factors, not considered by the other, because his experience may teach him it is necessary.

A compilation of values, or a method of determining these values for various materials to be used in connection with some acceptable strength formula, might be considered a standard for calculating the strength of spur gears.

Let us now assume that of a dozen proposals received our customer finds this difference of which I speak. We can readily imagine what conclusions he will draw as to our ability to design, and as to our knowledge of spur gears.

Some will say immediately that "we do not make suggestions or offer proposals of this kind," that "we only cut gears to customers' specifications," etc.; very good, but as time goes on more and more will be expected of us in this direction, and we cannot entirely ignore questions like these, if we are to maintain our standing, for this information can be had or can be found if we look for it.

It will also be said, "as we only make the gears and do not use them, we cannot know exactly the requirements and, therefore, can not guarantee them." That is true, but we would know that what we did offer would fill certain conditions which would be stated clearly in the specifications, and if they failed we could feel reasonably sure that running conditions were not as specified. If we cannot answer these questions pertaining to our own line, how can the man unfamiliar with this business do so?

### What Must Be Done

You may think that this one point has been dilated upon more than is necessary, but what has been said here is applicable to any branch of this industry; we must be ready to advise on all gear problems and be able to say authoritatively that this gear, material, method of hardening, or, if we group it into one word, design, is the best.

As was stated in the general letter sent to the sub-committees, there are already in existence standards which are applicable to this industry, and many of the members of this association have standards of their own, based on years of experience that might be used by all, if the modifications that may be necessary are made.

There is also in the hands of our members enough data of a scientific nature, which, if brought together and analyzed, would form the nucleus of a respectable library of standards. One of our first duties should be to collect these standards and this data and from them make revisions of the standards to suit all conditions, if possible, and from the data develop other standards.

It will be admitted that any private standard that has the merit of successful use to recommend it will lend itself to general adoption much easier than some new one developed from whole cloth; therefore, we would suggest to each sub-committee starting on their work that they take those already in existence, whether in this industry or out of it, and endeavor to rearrange it if necessary for general acceptance.

Our reason for suggesting this is due to the fact, as stated above, that they lend themselves more easily to general adoption, and, as we are at the beginning of this work, the quicker we produce some standardized result the more easily will the more difficult problems succumb, due to our experience.

There have been, or will be, committees appointed to standardize, so far as possible, the work pertaining to various sub-divisions of this business. These sub-divisions are now ten in number, as you will have seen in the "Journal," and which I will not now take the time to enumerate, and, as the need develops, others will be made.

### What to Standardize

While the types of gearing, or the subjects represented in these sub-divisions differ from one another in some respects, there are a number of functions common to many or all of them, and an endeavor is made here to outline some of the things that might be standardized and applied to each.

The question of quality is probably the most important one we have to consider, as quality, other things being equal, governs price.

In times not so long ago a gear was only a gear, but in these days, and as we know it, a gear is a work of art, the product of love, and years of experience. So, too, it is considered by many users, although they are not always ready to pay the price for this artistry.

What we produce must fill certain standards of quality. What these are must be determined by ourselves and the users of the gears. It would be folly for us to set standards of quality if they do not fit the conditions of use to which the gears will be put, and there will always be conditions that any standard we make will not fit. These must be taken care of as they arise. Nevertheless, we can adopt those that will fit the

*With the Brown & Sharpe Mfg. Co., Providence, R.I., and Chairman of the Standardization Committee.

credit to us.

To maintain and produce gears of quality and suitability, we should adopt standard specifications which, when filed out, should state clearly what is required of the gears in question, so that the extreme care and the time that is necessary to produce the best is not expended on work requiring only ordinary workmanship.

There are now so many different materials and qualities of material that the best for each service with the proper treatment, if any is required, should be investigated.

Standards for the proportions of all types of gears might be developed, these to conform, as near as possible, to the various ones now in use by our members and by other large users of gears. A well-proportioned gear is essential in providing a well-designed machine, and while it is not to be expected that anyone who now has patterns will discard them, such a standard would influence the making of patterns in the future. In fact, "the commercial incentive to adopt our standard proportions will be supplied by the consumer asking or even demanding gears which embody such standards."

Many foundries now carry gear patterns, and if we were to order castings without specifying what we wanted, we would not know whether it would be a web gear or an arm gear, nor how many arms it would have, or their proportions.

### An Instance

A number of reference books have been investigated for the proportions of spur gear blanks, and it is found that they all differ, in some respects using different symbols to represent the various factors; some call for six arms for all gears; others vary the number of arms with the diameter of the gear, and some do not consider the number of arms. It is probable that until we adopt a standard for this problem every text or reference book will offer its reader something that differs from the others, if not in fact, at least in looks.

In speaking of looks, every engineer knows how convenient it is to work with symbols that mean the same thing day after day, and how inconvenient it is to find when looking up references in connectio with some problem to find that while each author may use the same symbol, it represents a different value from that used by another. For instance, in looking up arm proportions, it is found that for the width of arm at the hub the letters A, B and (small) h are used. Now if we want to check up or compare the results of these different formulae we have to keep our wits about

To overcome this difficulty, which applies to gears in general, it might be well to have a nomenclature committee to authorize a standard set of symbols to represent the factors we use.

Working limits should be adopted to assure our standards of quality, such as amount of runout permissible in the blank and in the cutting, size of hole, whether to be from standard-to-small or large, width of keyway, etc.

Standard formulae for calculating the strength of all gears with values to cover the various factors used.

### Variations in Formulae

It might be interesting to state here that Mr. John Cooper, in 1879, when investigating the formulae then existing for the strength of spur gears, found 48 well-established rules for horse-power and working strength, differing from each other in extreme cases about 500 per cent. We do not think this difference would show in gears offered by members of this association, but it would be possible. It is thought that the Wilfred Lewis formula is now quite generally used, but even here the proper value for strength of material must be used, and it is thought that it devolves on the Hardening and Heat Treating Committee to furnish us with these data; the values for the strength of various material under different conditions of treatment, as published in the data sheets of the Society of Automotive Engineers, would form a good working basis for this.

One problem that has not received the attention it should is the question of wear, and, while a gear may be amply strong when considered from the breaking point, it may not be suitable as to wearing qualities. What can be done here we will not attempt to say, but the most reliable information will come from successful examples of long-lived gears. This information might be accumulated in time, and it might be advisable to have a committee to accumulate such data. This committee might be known as a library committee. Such a committee might investigate the literature on gears, and there is much that is of great interest and which might be brought to the attention of the association by this committee. It is possible that each committee can do something along this line, as their investigations will lead them to previous unexplored sources. This subject has received some consideration, but it is doubted if any concerted effort was ever made to accumulate and analyze it.

### Application of Standards

Let us now consider standards as they apply to the various sub-divisions, and as they appear before you in the "Journal." We are at a loss to offer specific suggestions for some of these sub-divisions beyond what has already been pointed out as applicable to all gears, but it is probable that our members can offer suggestions that will furnish the cue for other standards.

Bevel Gears.—Within the last few years this type of gear has been very highly developed, due principally to a perhaps greater advance in machinery for producing them, this machinery being the invention and product of two of our member companies.

They have developed formulae for calculating the dimensions of bevel gears, differing from the usual or standard practice. Reference is here made to the long addendum and the circular type gears, and these formulae for calculating might be made standard whereby all of us may calculate alike the dimensions for these gears, as their growing use for general gearing demands that long addendum or circular type gears be made to some standard and not continue to be special types as they are now. There are now, as in the past, and will be in the future, many bevel gears cut with rotary cutters, and some consideration might be given to the proper cutters to use in cutting them.

Spur Gears.—By far the most used gear, and the one that has received the most consideration theoretically and practically. Most of the theory of gearing can be studied from it, and there are more distinct methods of producing it than any other gear. For this very reason any standard adopted must be one that does not conflict with any method of production, but should be applicable to each and all of them.

Worm Gears.—Within the last few years worm gears have come into their own, and are being used to transmit greater powers at higher speeds than was thought possible previously, but even now, with this great development, the design is not based upon complete analysis. There are so many conditions that enter into the design of worm gears that it is almost impossible to design a drive with any certainty of success unless we have before us a very similar successful design.

It would be well for the committee on worm gears to investigate the many successful drives now in existence and try to deduce some tangible working basis of design. This will not be an easy thing to do, but a start might be made towards this by getting in touch with the engineering societies. It is believed that the American Society of Mechanical Engineers have given this matter some consideration.

There is a great lack of uniformity in calculating the dimensions of both the worm and the wheel and also in the method of producing the worms, as well as in selecting the material from which to make them. To those of us who make or use hobs, it is known that the hob must be as near like the worm as possible and oftentimes when a customer sends in the wheel to be hobbed, intending to cut the worm himself, the question will arise, especially with multiple-threaded worms, just how the worm will be cut, whether with a tool or with a cutter. And even when we know a tool was used, was it made straight-sided on the normal or on the axis? If a cutter was used, was it straight-sided or was it formed to produce a straight axial section? If made on the normal section, what tooth proportions were used, those based on the axial pitch or on the normal pitch?

The committee should look into this subject and determine upon some standard specification sheet where all of these points will be considered.

### Worm Making

It would be possible to develop standard formulae for worm and wheel dimensions that would permit us all to produce similar gears under regular conditions. For instance, if we were asked to make a worm and wheel of any diameter with single thread it is probable that all of us would make the same worm in every respect except length, where we would probably differ, and the same wheel, except for width of face, but if we were to make a six-threaded worm it is probable that we would not produce the same worm or wheel.

Those who are equipped with a worm thread milling machine would use it to cut the worm and would use a straight-sided cutter, while others would use a lathe with either a straight-sided axial tool or a straight-sided normal tool. If these three methods are pursued the thread of each worm on any section would be different from the others, and any hob could be right for but one of them, the hob being made to the same system. Again, when the angle of thread with axis becomes less than 72 degrees it is the practice in the works of one associate to make the hob with spiral grooves, as it works better than a straight-grooved hob of this angle, so, too, they then calculate the tooth proportions from the normal pitch.

With worms of steep angle of thread, say from 45 degrees to 60 degrees with the axis, it is best to use a greater presure angle, as it produces better working conditions; in fact, it is quite impossible to make a hob for a 45-degree angle of thread worm of standard depth and pressure angle.

The proper length of worm and width of face of the wheel might also be investigated in this connection.

Herring-bone Gears.—It can be said of herring-bone gears, as of the others, that their greatest development has come only recently. This branch of the industry is highly specialized and any suggestions must come from others. What little experience I have had with these gears has taught me that they must be made extremely well if they are to fill their mission properly, and the sub-committee should take the initiative in determining what degree of accuracy should be demanded.

Sprockets.—This is another highly specialized branch of gearing and out of our control, in so far as the success of the drive depends on the chain which we do not make, as well as upon the sprocket. Any work this committee does should receive the sanction of the chain manufacturers.

We know that some chain manufacturers hesitate to furnish chain to run sprockets they do not cut themselves, owing to the lack of knowledge of many who would cut the sprockets, as to how they should be cut, and they may welcome the aid that this association can give they to make more successful the use of their product.

Composition Gearing.—For many years we have been called upon to furnish gears of other material than metal, and until recently these gears were usually made of rawhide or fibre, but now the two largest electric companies have developed a fabric composition that is being used to greater extent perhaps than any of the older materials. The working standards for any of this material will be different from those used for metal, and the committee will be governed by those who are most familiar with these gears.

Gears and Pinions.—"As applied to electric railways and mine work." As the members of this committee are associated in their daily work with this type of gears, we feel that they are more competent to suggest what is applicable to these gears, and wait upon them to furnish the initiative.

Hardening and Heat Treating Committee.—This committee has it in its power to do as much or more than any other committee to help clear the atmosphere on a most important subject. We all know that the best and most durable gears are those that are properly heat treated or hardened, and if they can suggest or develop standard methods to handle the various steels that are used for gears they will perform a service of inestimable value to every manufacturer and user. We believe that any steel manufacturer would be glad to help them in their work, for it would be to their profit to do so.

Inspection Committee.—This committee is a most important one, for upon it devolves the duty to develop standards of inspection suited to every kind of gear. Its members should endeavor to determine the working limits to suit all kinds and sizes of gears and the method of testing them.

To do this the committee, of course, should work in conjunction with each of the others, as we must consider the committee representing any kind of gear the authorities on that kind.

If any member of this association thinks that the work of these standardization committees is going to be easy we wish they would look up some of the reports of committees on standardization, as submitted to some of the engineering societies, such as those submitted to the American Society of Mechanical Engineers, and see for themselves the great amount of labor that must have been expended on them. We do not mean to say that all of the standards we may adopt will be the result of great labor, but to make a standard to fit all conditions we must deal with many men and many conditions, and this will take time, and the longer the time the greater the labor. Therefore, as we said before, let us start on the easy things, if there are any, so that results will show quickly, thereby gaining experience and accustoming ourselves to the use of the standards we develop.

---

A NEW alloy of copper and nicked is claimed to have unusual properties, being permanent, non-corrosive, and capable of withstanding higher temperatures than German silver.

## FOREIGN TRADE AFTER THE WAR

E. M. Herr*

OUR business men, since the close of the Civil War, have been so engrossed with the development and care of our domestic trade that the selling of goods in foreign lands has been of little interest because in comparison with domestic trade it was not only far less profitable but also much more difficult to handle.

Our geographical remoteness from other nations, and consequently our unfamiliarity with their language and customs, also tended to cause foreign trade to languish.

On account of this apathy toward foreign trade, rather than a contributing cause of it, came the decline in shipbuilding in America an dthe remarkable decrease in the American merchant marine. This was hastened and accentuated, to be sure, by adverse legislation, culminating in the Seamen's Act of March 4th, 1915, until by the fall of that year the only American steamship line in foreign trade on the Pacific Ocean was driven from the sea.

On September 7th, 1916, the Act creating the United States Shipping Board was signed and the means for the present unprecedented activity in the acquisition and construction of merchant shipping was provided. $50,000,000 was provided in the original Shipping Act of Congress. Our country's entry into the Great War, however, caused nearly $2,000,000,000 to be placed at the disposal of the Shipping Board, which now has under construction upwards of eleven hundred vessels and is endeavoring to add, during the year 1918, more gross tonnage to the merchant marine of the United States than was comprised in the entire American Merchant Registry three years ago.

This enormous addition to our merchant marine will be still further increased, if the war continues beyond another year, and even should the war end sooner the very large and splendidly equipped shipbuilding yards now being provided on our coasts will undoubtedly enable our merchant fleet to be further enlarged to provide ships to replace those destroyed by the submarines during the war.

### Shipping Before the War

What this shipbuilding program really means will be better understood by a comparison of more statistics of the world's shipping before the war.

At the outbreak of the Great War, the merchant shipping of the world, of 100 tons and upwards, according to Lloyd's Register of Shipping, consisted of 30,836 ships of 49,089,552 tons, of which there were 24,444 steamers of 45,403,877 gross tons and 6,392 sailing vessels of 3,685,673 net tons.

Great Britain and colonies owned 15,123 steamers of 20,523,706 gross tons.

All belligerents, except United States, 16,331 steamers of 32,334,893 tons.

### Ship Ownership

United States July 1st, 1915, owned [illegible] per capita.

Great Britain July 1st, 1915, owned [illegible] per capita.

World's merchant marine tonnage 1890 to 1915 increased 122.7 per cent.

World's merchant marine steam tonnage 1890 to 1915 increased 252.2 per cent.

United States merchant marine total tonnage 1890 to 1915 increased 30.9 per cent.

United States merchant marine steam tonnage 1890 to 1915 increased 161.1 per cent.

In 1890 the United States had 20 per cent. of the total tonnage of the world and in 1915 11.96 per cent.

### Ingenuity Uses Structural-Steel Methods

Shipbuilding is developing a new era, brought about by the much higher wage rate here than in foreign countries. Inasmuch as American engineers have demonstrated their ability to underbid the world in the cost of erecting the structural steel used in our high buildings in the face of higher wages, it is possible to carry out the same operation with another form of structure—namely, a ship—and show equally brilliant results from an economic point of view. This idea has been so developed and perfected that the ships of the Emergency Fleet Corporation are being built of steel plates and shapes, all the laying out, cutting and punching of which is done so accurately by the manufacturers of these products in their shops before shipment to the shipbuilding yard that on their arrival they are assembled and riveted in place without re-handling or extra labor.

### Our Marine Equipment Plays Its Part

These ships are also being provided with high speed steam turbines geared directly to the propeller shaft. These turbines are very much more economical in steam consumed per horsepower delivered to the screw propeller and are at the same time very much lighter and smaller than the ordinary reciprocating marine steam engine, and even with the gearing required occupy much less space.

By the use of this lighter, smaller and more efficient propelling machinery, several important economies and improvements are effected:

Cargo space and tonnage are saved and the freight or passenger carrying capacity increased.

The greater economy of the turbines means less coal bunker space, or, with equal space, larger steaming radius.

The turbines are more easily and cheaply inspected, maintained and operated.

As an example of the advantage of high-speed turbines geared to the propeller shaft over the most modern steamship equipped with direct-driven steam turbines, an article was published in *International Marine Engineering* for October, 1914, showing the results which would have been obtained had the steamship "Lusitania" been equipped with high-speed geared turbines instead of the direct turbine drive installed on that ill-fated vesel. This comparison showed that with the geared turbines only three-quarters of the boilers would have been required, a reduction of 40 per cent. in weight of machinery secured and more than 25 per cent. of the coal saved. This change would also have released a large amount of space for additional revenue tonnage, all resulting in a total estimated saving of $898,000 per year in the operation of this vessel.

Our Government, recognizing the advantages of the high speed geared turbine in ship propulsion, has, as stated above, specified this design of machinery in the vessels now building in the yards of the United States Shipping Board.

### What Follows the Ships?

Assuming we have adequate merchant marine with ships economically built and efficiently propelled, what further is necessary to enable our merchants and manufacturers to successfully develop our foreign trade after the war?

### Our Competitors

Let us first consider what competition we will find most difficult. Some light on this important subject may come from an examination of the competition met before the war. Then England and Germany were the leading nations in export trade, the United States being third. In 1913 the combined imports and exports of these countries in dollars were:

England, 7 billions; Germany, 5 billions; United States, upwards of 4 billions; France, 3 billions; Belgium, 1.7 billions; Russia, 1.5 billions; Austria-Hungary, 1.2 billions; Italy, 1.2 billions.

Imports exceeded exports in all the above countries except the United States and Russia. For Great Britain the difference was $650,000,000; for Germany $160,000,000, and for France $315,000,000.

This difference is paid for by Great Britain through ocean freights, income from foreign investments and the trade in commodities among the countries. The other countries pay for their surplus imports in general in the same way, a larger amount, however, being paid in trade, which means that they are all vitally concerned in their foreign trade and are, therefore, the great trading nations of the world, and the largest and best customers of the United States. We, however, take from them more of their manufactured products—they from us more of our raw products. As we develop in ability to reduce the cost of our manufactured products and learn how better to meet the exact requirements of their trade, we will gradually increase our exports of manufactured products to these countries. This is especially true now that we have become a creditor instead of a debtor nation.

### Opportunities in Smaller Countries

The opportunity for such increase is, however, much better in those countries of smaller industrial development, like Russia, Japan, China and the South and Central America countries, all largely dependent on imports from foreign countries to supply their need for manufactured goods.

All trade is reciprocal, and we must not forget that if we are to supply a nation with the products of our industry we must take from them a considerable proportion of this trade in their products or establish some trade or financial relation which will enable them to largely pay us in trade for our goods. It requires co-operation among our manufacturing exporters to bring about the best results in this as in other trade matters.

We are fortunate in having a national organized body of manufacturers for this very purpose, which is rapidly becoming more effective and influential. I refer to the American Manufacturers' Export Association of New York, of which all manufacturers interested in export trade should be members to secure the results of close co-operation in foreign trade problems and be brought into close contact with that related organization—the National Foreign Trade Council—which has done and is doing such splendid work for the best development of foreign trade.

## NEW PROCESS OF TUNGSTEN FILAMANUFACTURE

A NEW German process for making lamp filaments of tungsten involves forming the lamp filament out of one long crystal. It is impossible, according to the "Electrician" to make tungsten crystals form gradually out of a mixture of tungsten powder and thorium oxide. The mixture is squirted through diamond dies into a filament of 0.02 m.m. to 1 m.m. diameter. This filament is then drawn through a chamber in which it is rapidly heated to a temperature of 2,400 deg. C. to 2.600 deg. C., and with a velocity of about 2.5 miles per hour, which is rather slower than the crystallization velocity of tungsten, so that a single crystal of indefinite length is formed. The chamber is filled with a neutral gas, and the heating is performed in two stages by a pair of electrically-heated coils, through the centre of which the filament is passed. The filament in this state is ready for use in a lamp without further treatment. It is softer than drawn tungsten wire at low temperatures and hard at high temperatures, which makes it particularly suitable for use in lamps. Filaments consisting of a single crystal of 25m. length have been produced in this manner.

ACCORDING to the "Revue de Metallurgie, the riches in iron of Brazil are manifest. The mountain of Itabira do Matto Dentro is said to have a plentiful outcrop of iron ore containing 70 per cent. of iron. Situated in virgin forests, an abundance of charcoal would be available for the furnaces. Moreover, there is ample water power at hand for the operation of electric furnaces for the manufacture of steel and other finished products.

# Principles & Practice of Mechanical Sketching & Drawing--I.

## Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simpler Types—A Practical Course Prepared Especially For Younger Men and Newcomers in the Industry

By Terrel Croft

MECHANICAL DRAWINGS, so someone had aptly stated, afford a universally-understood means of conveying information about engineering matters. Thus a mechanical drawing, rendered in accordance with the prescribed practices, can be understood by any man who can read drawings, regardless of the language which he speaks. An engineer who understands only the Swedish or the Japanese language can, assuming that he understands certain well-established conventions, easily read a drawing prepared in North America and in accordance with North American methods.

Hence every man who has anything, either direct or indirectly to do with engineering should know how to make and to interpret mechanical drawing and sketches of the simpler types. This does not mean that it is desirable that every man should be a skilled draftsman or designer. But it does mean that he should be able to produce neat and decipherable sketches or drawings of the ordinary parts of machinery. And he should be able to read ordinary working drawings quickly and without effort.

### Scope of Articles

Every practical man who has served his apprenticeship and been through the mill understands the value of a sketch or drawing. Hence the statements in the preceding paragraphs contain nothing new for him. But the younger men or those who are just entering the engineering profession may not appreciate the importance of these things.

Now the series of articles of which this is the first is going to constitute a practical course in practical drawing and sketching, prepared especially to satisfy the requirements of these younger men. This course will not be laid out on the basis usually followed in the average school or college. On the contrary only the things which it is essential and desirable that the practical man should know will be treated. The thousand and one non-essentials which, from an academic standpoint, may be exceedingly interesting, will not be given consideration. Particular attention will be accorded to the preparation of working "sketches." The reason for this is that the practical man on the job will probably have to make an average of twenty sketches to one finished drawing.

If something breaks and repair parts must be ordered, it is up to the man in charge to make an understandable sketch of that part, or if additions or alterations must be made in an existing installation—and, as the practical man knows by sad experience, this state of affairs occurs only too often—sketches or finished drawings must be produced on which quotations can be made and from which the work can be installed after the new outfit has been purchased. Furthermore, if new equipment or apparatus is to be bought, the individual who is responsible should be trained to read the drawings so that he may check them for general arrangement and design and so that he may prepare himself [illegible] operation when they arrive.

### Sketches and Drawings

The distinction between a sketch and a drawing, as these terms will be used in this series of articles, is this: A sketch is a rough sort of drawing, made usually with a pencil only, but sometimes inked in, upon which no time has been spent in order to obtain a finished appearance. A drawing is always finally rendered in ink, usually on tracing cloth, but sometimes on drawing paper, and is finished with a border line and a complete title to be preserved as a permanent record. Usually it is justifiable to spend the amount of time necessary to insure a neat and finished appearance on a drawing because it may be referred to and used many times in the years to come.

The preferable sizes of sketches and drawings is a thing that is worthy of careful consideration. Frequently, when the first drawings are made around a plant or shop, they are laid out on sheets of many odd and different sizes, and hence are difficult to file, in that they may not fit the regularly-manufactured filing cabinets. Furthermore, when the sheets are of a number of odd sizes it is inconvenient to finger through a pile of them in order to pull out the one which is required. It is just as easy and as cheap to start systematically with a standard system of sheet sizes and to follow it consistently in the future.

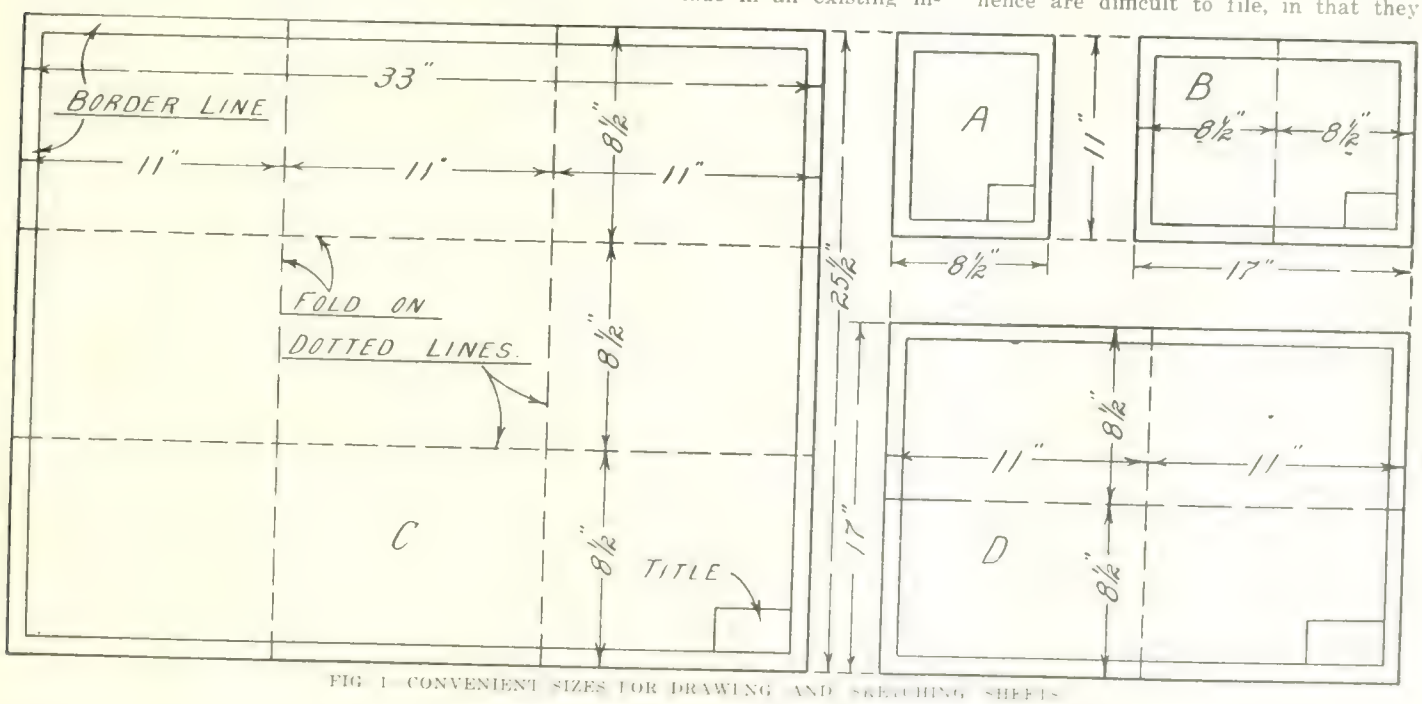

FIG. 1. CONVENIENT SIZES FOR DRAWING AND SKETCHING SHEETS

### Sheet Sizes

There are many different systems of sheet sizes in use in different shops and

*Registered in accordance with the Copyright Act.

system will answer every requirement. However, the one system of sheet sizes which is to be described has shown itself during a period of many years of experience to be the most satisfactory of any which have come to the writer's attention.

The basis of the system which we ad- sheet. This is the size of the usual sheet of business correspondence paper. The smallest size sheet, A, of the series, 11 in. over all. Sheets of this size can be readily attached to and filed with correspondence and can be stored in the standard vertical correspondence files. All of the other sheets, B, C, and D, have dimensions which are even multiples one way or the other of the $8\frac{1}{2}$ in. x 11 in. unit. Therefore, blueprints made from the B, C, or D sheets will fold accurately can be mailed with or filed with correspondence with minimum confusion and waste of space. In the average plant only three sizes, A, B, and C, and ordinarily required.

Because of the fact that it is desirable to have as few standard size sheets as possible, the D size should not be used at all unless special conditions justify its adoption. The steel companies and many of the engineering offices have used extensively a sheet which measures 24 in. x 34 in. over all. The C size sheet illustrated in Fig. 1 has dimensions sufficiently near 24 in. x 34 in., that it can ordinarily be substituted for the 24 in. x 34 in. sheet. Many shops find that they can get along very nicely by using only the A and C size sheets. The C size is then utilized for assemblies and general drawings, and the A size for details and sketches.

The selection of drawing paper is of sufficient importance where much work is done to justify consideration. The general tendency appears to be to use papers which are more expensive than is necessary. On the other hand it is uneconomical to use too cheap paper. For finished drawings or for design work a tough, relatively thick paper, which will stand considerable erasing is requisite. The "detail" paper, which can be purchased in rolls from the drawing supply houses and which is a light buff in color answers these requirements admirably and is relatively inexpensive. This paper also has the advantage that it does not become brittle with age, which is an essential feature where

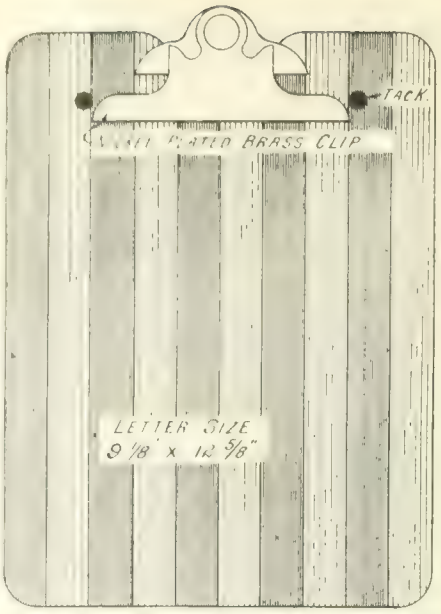

FIG. 3. CLIP BOARD FOR HOLDING SKETCH PAPER.

paper drawings are to be reserved for record. Furthermore, the buff tint appears to produce less strain on the eyes, particularly where the work is done under artificial light, than does brilliant white paper. However, this buff detail paper is not altogether satisfactory for sketching because it is too hard to take the smooth even line produced by a relatively soft pencil.

In a pinch almost any kind of paper can be used if the drawing is not for permanent record. The writer has used wrapping paper borrowed from grocery stores and the dark brown paper used for general bundling and it served the purpose well.

Paper for sketching (assuming, of course, that the sketch is not to constitute a permanent record) can be of any tough, open-grained material. Inasmuch as most sketches are made on $8\frac{1}{2}$ in. x 11 in. sheets, the writer's practice has been to use for this purpose sheets of ordinary bond correspondence paper. He finds that 16 lb. Hammermill bond is very satisfactory. As will be explained later, squared or cross-section paper (Fig. 2) is often very satisfactory and economical for sketching.

### Materials and Methods

Sketching will be treated first in this series of articles. The materials and the methods used in mechanical sketching will be given attention, and finally drawing and tracing will be treated.

A clip board constitutes an admirable sketching pad. Such a board, sometimes called a letter file, is illustrated in Fig. 3. In use the sketching or cross-section paper is held under the nickel-plated brass clip on the wooden back, which is about 5-16 in. thick. It is composed of hardwood strips glued together to prevent warping, and provides a smooth working surface and a rest for the hand. One of these boards can be conveniently carried to any part of the shop so that the sketcher who owns one may be sure of a satisfactory working surface wher-

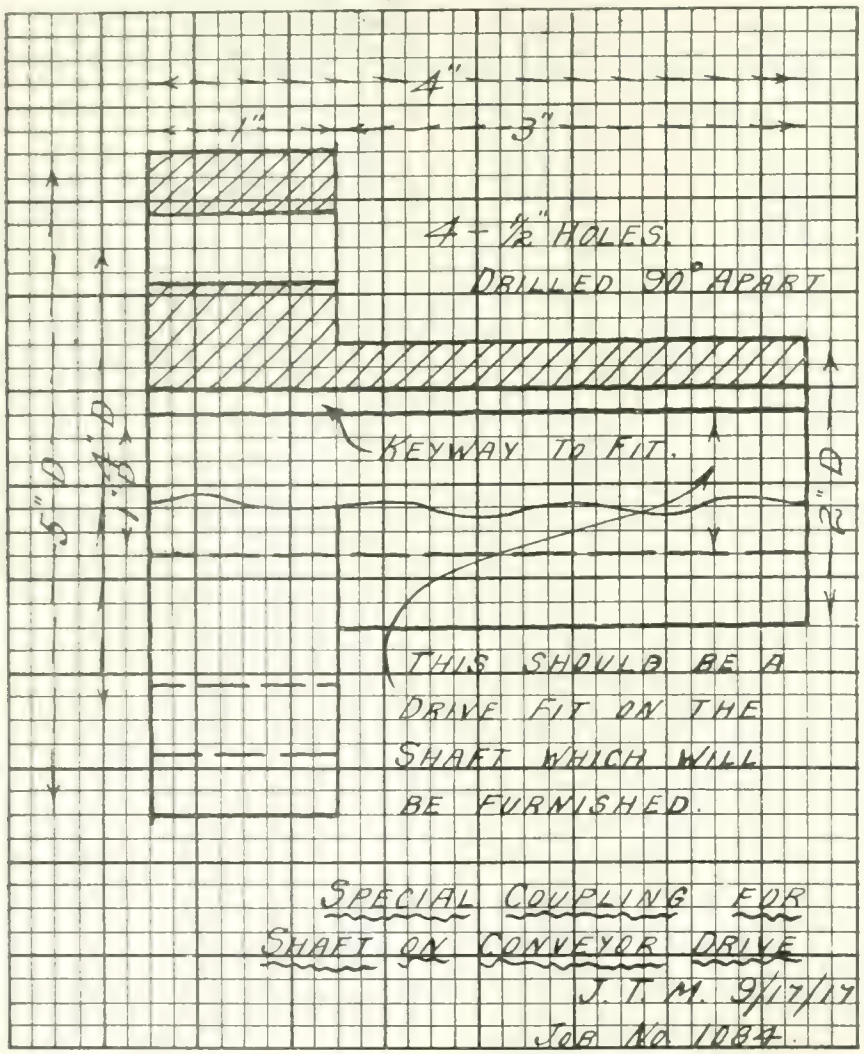

FIG. 2. EXAMPLE OF TYPICAL SKETCH DRAWN ON CROSS-SECTION PAPER.

ever he goes. When he starts out to make a sketch the board may be "loaded" with a number of sheets of plain and of cross-section paper. After he makes one sketch he withdraws this finished

FIG. 1 HOW TO SHARPEN A PENCIL.

sheet from the top of the file and places it at the bottom so that it will not become soiled. A couple of brads or tacks should be inserted in each board as shown in Fig. 3 to prevent the sheets from slipping too far up under the clip.

A clip board will cost from about 35c to 50c. There are certain precautions which should be observed in purchasing. Some of the boards on the market are not satisfactory for holding sketching paper. The clip itself should be of brass. Some of these clips are stamped from sheet iron, and while the nickel finish on them is bright when they are new, they will, after being used a while, due to perspiration and moisture, become rusty and soil the sketching papers. One can test the metal with a small magnet. If it is nickel-plated iron the magnet will stick to it, whereas if it is brass there will be no attraction. Furthermore, some of the boards have clips which will not remain open, whereas others, due to a little spring catch, will automatically remain open while the sheets are being changed. This feature is a great convenience.

Squared paper is a great time saver when sketches are to be made. Fig. 2 illustrates a sketch made on an 8½ in. x 11 in. sheet of this kind of paper. The paper may be purchased either in pads or in sheets and costs from one-tenth of a cent to ½ a cent a sheet, depending on the quality of the paper on which the squares are printed, the number of squares per inch and the quantity purchased. For general mechanical sketching the paper which has lines ⅛ of an inch apart each way (Fig. 2 is reproduced from such paper) is the most effective. Sketches can be easily and [illegible] ed paper. Even if they are not made to scale, the horizontal and vertical lines afford a guide whereby the sketch can be easily, rapidly, and neatly made.

If it is desired to make blueprints from the sketches, very thin squared paper, specially manufactured for this purpose, can be purchased. Then if the sketch is drawn in on it either in heavy pencil lines or with India ink satisfactory prints can be obtained.

### Quality of Pencils

Pencils for sketching should be rather soft, but the grain of the graphite should be even and contain no hard spots. In other words, it is not economical to use a pencil which is too cheap. A hard pencil is not satisfactory for sketching because it is difficult to control. That is, with a properly sharpened soft pencil one can obtain at will a fine line or a rather bold one. Such variation is impossible with a hard pencil. For his own work the writer has found a pencil made by the American Pencil Company of New York, and called "Velvet" No. 2.557 as satisfactory as any. Each of these pencils has a red rubber eraser in the end, which is a great convenience. The "Velvet" pencils cost 5c each when purchased separately, but when bought in boxes of one dozen each the price is about 50c per dozen. It does not seem

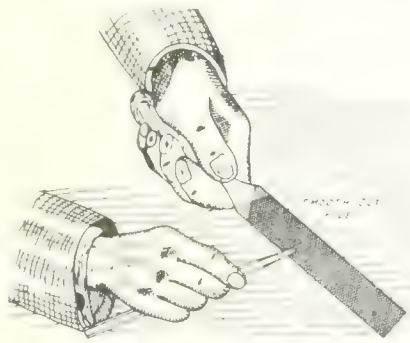

FIG. 3 FINISHING PENCIL POINT WITH A FILE.

FIG. 4 CORRECT METHOD OF SHARPENING A PENCIL.

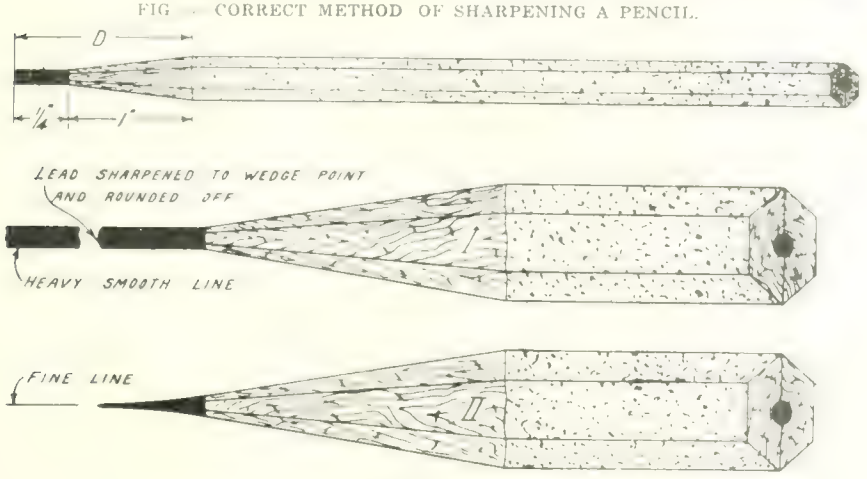

FIG. 6 DETAIL OF POINT.

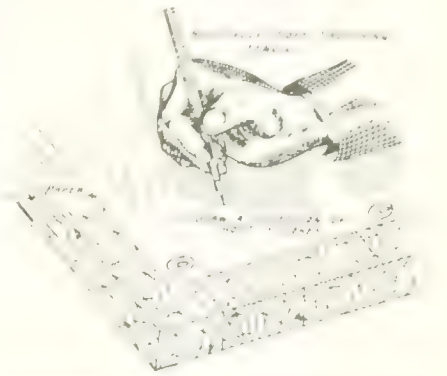
that it is necessary to pay more than this for sketching pencils.

In sharpening the sketching pencil certain precautions should be observed. Probably every fellow thinks that he



CORRECT METHOD OF HOLDING A PENCIL FOR SKETCHING A VERTICAL LINE.

knows how to sharpen a pencil, but in this, as in many other things, there is one way which, all things considered, is the most satisfactory and economical. The first operation is to cut the wood away from the lead as shown in Fig. 4. Needless to say, the knife blade should be sharp, and kept so, hence it should not be permitted to cut into the graphite. The pencil should be held, as illustrated in Fig. 4, in the left hand and the knife blade drawn with the right toward the pencil point, the movements of the blade being controlled in the meantime by the thumb of the right hand resting against the wrist of the left hand. It is a mistake to endeavor to sharpen a pencil in the left hand and whittling on it out into space because, where the pencil is held in this way it is impossible to control the blade properly, and the consequence is that the manipulator breaks the graphite point off about as rapidly as he whittles away the wood which exposes it. Fig. 5 suggests about how the sharpened pencil point should look. The exposed graphite should be in the neighborhood of ¼ in. in length and the wood should be whittled back for approximately 1 in. If the distance (D, Fig. 5) is too short, one cannot get the right kind of point on the pencil, and if it is too long the working end of the pencil is weakened excessively.

In finishing the point of the sketching pencil the excess graphite (Fig. 7) is ground away so that the exposed lead takes the wedge form delineated in Fig. 6. With the point ground as shown (Fig. 6-I) the draftsman may hold the pencil (Fig. 6-I) so that the flat side of the point is presented to the paper when he desires to draw a heavy outline or boundary line. When it is desired to draw a fine projection center or dimension line, the pencil is rotated so that its fine edge is presented to the paper as shown at II. In grinding the point, a smooth-cut file (Fig. 7) is about the most convenient tool. While fair results can be obtained with almost any sort of a flat file, a new, sharp, smooth-cut tool will justify its cost. If a file is not available a strip of fine sandpaper or medium

Erasers

tainable. Some of them are worthy of

FIG. — CORRECT METHOD OF HOLDING PENCIL FOR SKETCHING A HORIZONTAL LINE.

consideration and some are not. When sketching, unless the sketch is to be inked in with a fountain pen (the fountain pen method is described below) only one kind of eraser is required. For this general service, the eraser manufactured by Eberhard Faber, of New York, and known as the "Ruby" 112 has been found very satisfactory. This is wedge-shaped at each end and measures over all 2¾ x ⅝ x 5-16 ins. The price of this eraser is 5c. Where not a great deal of work is being done, the red eraser in the end of the "Velvet" pencil described above will be satisfactory. Where sketches are inked in with a fountain pen the pliable or cleaner eraser should be used for rubbing out the pencil lines after the inking in has been done. For this service the Hardmuth eraser, which is manufactured in Austria and now difficult to obtain, gives good service. Another similar eraser which apparently does quite as well is the "Janus" No. 70-13-12, manufactured by A. W. Faber, Newark, N.J. Both of these cleaner erasers measure 1 5-16 x 5-16 x 2 ins. and cost about 6c each.

A fountain pen may be used very effectively in making sketches. The procedure is first to pencil the sketch in and not to erase any of the pencil lines, construction or otherwise, which were used in mapping out the job. That is, in making a sketch it is usually impossible to have the pencil lines go where they should the first time, but with this method when a pencil line is drawn in the wrong place, do not at this time erase it, merely draw another in the right place and proceed. After the draftsman has determined the form of his object he then inks in with the fountain pen—using the ordinary writing fluid or fountain pen ink—the lines of which will comprise his sketch, then all of the pencil lines that should be obliterated are rubbed out at once with the soft rubber. By following this procedure the time that would be wasted in constantly erasing and changing pencil lines is saved.

The correct methods of holding the sketching pencil are shown in Figs. 8 and 9. Any line which is sketched in should comprise a series of short strokes, that is the sketcher feels his way along as it were. It is not feasible to draw a long continuous sketch line with one stroke of the hand. The base of the hand and the forearm should rest on the drawing board or some other support; the ends of the successive strokes should not be lapped over one another but they should join so as to form a continuous smooth line. When the line to be sketched is a vertical one, the hand rests on its side and the strokes are executed by movements of the fingers, as detailed in Fig. 8. In sketching a horizontal line (Fig. 9) the whole hand is moved, hinging from the wrist, whereby a series of short strokes is produced, it being necessary to move the hand from location to location as the development of the line proceeds.

In arranging the different views of the object to be sketched on the sheet it is usually desirable, though not by any means always feasible, to put the plan view (see Fig. 10) in the upper left-hand corner, the side elevation to the right of the plan view and the end elevation below the plan view. This arrangement provides space for the title in the lower right-hand corner.

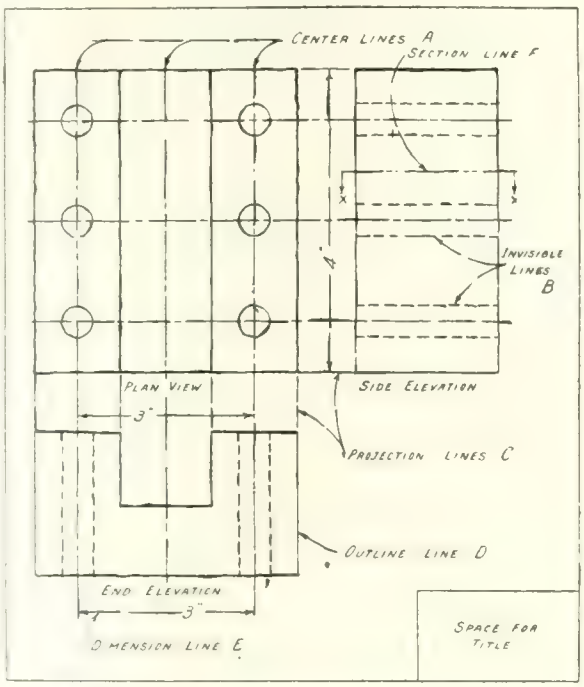


FIG. 10. DESIRABLE ARRANGEMENT OF VIEWS ON A SHEET AND SIGNIFICANCE OF DIFFERENT LINES.

**Lines and Their Purposes**

The different kinds of lines which are used in making a sketch have different meanings. In other words, each kind of a line is in itself a symbol, hence, to understand drawings one should appreciate the significance of these different symbols. Unfortunately, practice regarding the meanings of the lines of the different kinds has not been standardized universally. The practice which will be followed herein (and which is explained in the paragraphs immediately following) is, it is believed, in line with best usage.

All of the different lines which will be used in this series of articles are black lines. Formerly it was the practice to use for mechanical drawings lines of different colors, red, blue, and the like to indicate different things, but since it is impossible to accurately reproduce these colors on a blue print or on a page which is printed only with black ink, their use has been discontinued in practical engineering; experience has shown conclusively that mechanical drawings which are entirely legible can be constructed wholly from black lines.

Boundary lines or outlines are those which indicate any edge or boundary of a surface, when that edge or boundary is visible from the location from which the object (which is shown in the drawing) is viewed. Boundary lines are always full continuous black lines, as shown at D in Fig. 10. They are frequently made quite heavy so as to emphasize the contour of the object.

Invisible lines are used to show any edge or boundary of a surface when that edge or b oundary is concealed from view. As suggested at B, Fig. 10, dash lines with relatively short dashes are used for this purpose. The spaces between the dashes should be about ¼ the length of the dashes. Whenever two lines consisting of dashes lie close together and are parallel, the breaks between the dashes should be staggered; where this is done the course of each broken dash line can be followed readily with the eye.

Center lines are imaginary lines, comprising a series of alternate dashes and dots (A, Fig. 10), around which the object of the drawing or certain parts thereof are symmetrical. In laying out a drawing or sketch, usually the first step is to plot the principal center lines.

Projection lines are imaginary lines (C, Fig. 10) connecting, in the drawing, the same edges of surfaces in the different views. Thus, a projection line is used for projecting the position of a surface or edge in one view to the position of that surface or edge in another view. Projection lines are also drawn as shown in the end elevation of Fig. 10, where it is desirable to project the outline of an object so that a dimension line, W Y, can be drawn between the projection lines. A dash line composed of rather long dashes is used for a projection line.

A section line consists (F, Fig. 10) of a series of dashes with two dots between each pair of dashes. Section lines are used to indicate the location at which a section of a drawing is taken. This

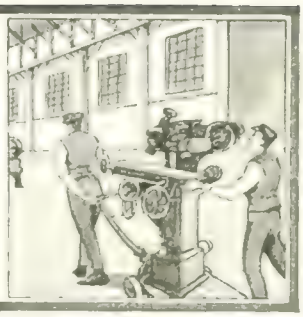
# DEVELOPMENTS IN SHOP EQUIPMENT



*Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

## SHELL BOURLETTE GRINDERS

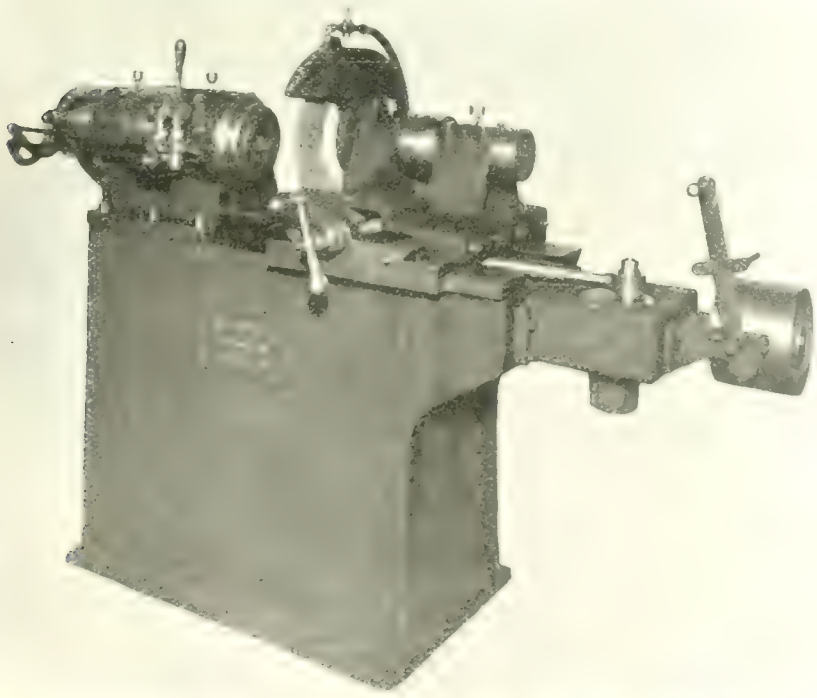
THE manufacture of new types of shell in Canada, the 75 mm. and the 155 mm. calibre, has called for special machinery for certain operations, one of these being grinding the bourlette. Part of the bourlette is flat and it was for this work that the machines were designed.

The Ford-Smith Machine Co. of Hamilton, Ont., designed and is building a new line of machines for grinding the bourlette. It is a development of their well known grinders but embodies a number of special features which will be observed in the accompanying illustrations. The grinders are made in two sizes, for the 75 m.m. and 155 m.m. shells respectively, the machine for the latter being of course larger and a heavier construction, although the general design is practically the same for both grinders. The machines have already proven to be a success for the firm that placed the first order has already sent in a repeat order for a larger number of grinders. The machines were tested and found to be entirely satisfactory for the work they were called upon to perform.

One of the chief problems that had to be considered was handling the work, for the actual grinding of the bourlette takes but a little time. An air chuck was found to meet the requirements of the situation, so both types of machine are fitted with a quick acting air chuck. The 155 m.m. grinder has in addition a swing arm to enable the shells to be handled expeditiously and so speed up the operation of the machine. Being a heavier shell than the 75 m.m., the swing arm is of considerable assistance to the operator as well as in speeding up production. No special provision of this kind is necessary for the 75 m.m. shell.

Apart from the differences already mentioned, the operation of these grinders is identical. The shell to be ground is gripped in a spring collet in the headstock spindle and is operated by the air chuck. The headstock spindle is revolved at a moderate speed on the 75 m.m. machine, by means of a large pulley on the spindle, while on the 155 m.m. machine it is operated through gearing. The emery wheel has an independent drive and is mounted on a heavy spindle which runs in bearings on a carriage as shown. The carriage is adjustable and is traversed by means of a worm drive, back and forth across the work, while the wheel is fed as desired, the feed being regulated by means of a gange. The emery wheel is provided with special flanges and suitable splash guards.

A lubricant pump is provided, the tank for the lubricant being cast integral with the bed. In some cases a pump is not required, for in many munition shops where only a few thousandths are left for finish, grinding the operation is done dry, in which case the wheel hood is connected to a dust exhaust system. There is nothing of a complicated nature about these grinders, only unskilled help being required to operate them. The operation is rapid and accurate, the speed of production depending largely upon the amount of metal to be removed. The accompanying illustrations show the general design of these machines, the principal dimensions being given below.



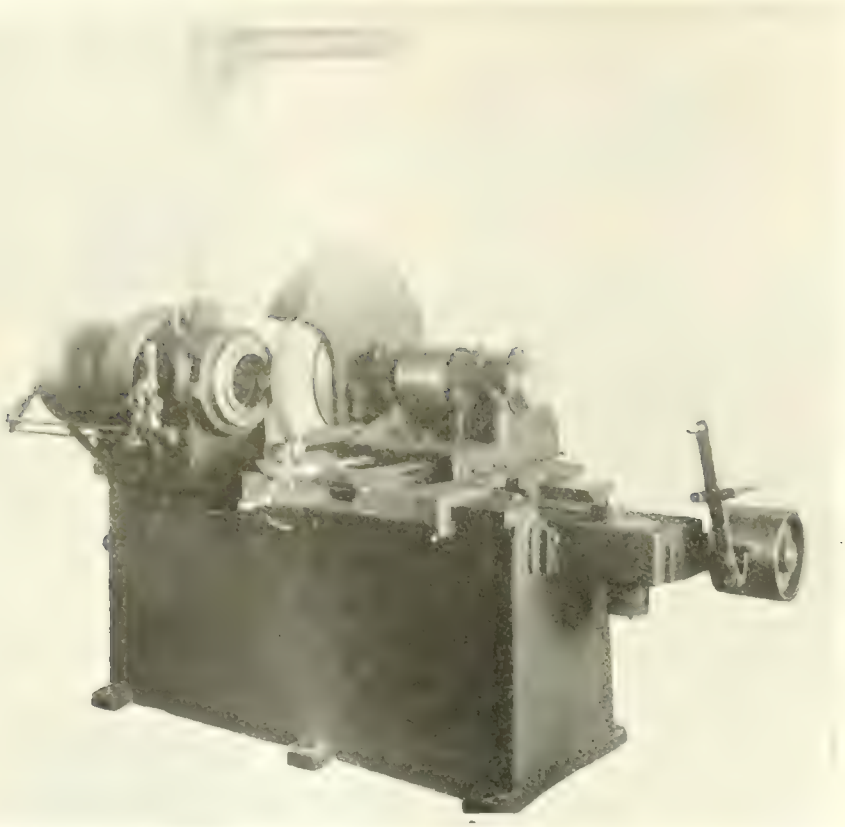
SHELL GRINDER FOR BASE AND BOURLETTE OF [illegible] PDR. AND [illegible] MM. H[illegible]

## BAND RESAW

The band resaw and scroll saw illustrated herewith is made by the Oliver Machinery Co., Grand Rapids, Mich., and is recommended as a general utility tool of more than ordinary work. Its adaptability is shown in its ability to resaw expensive lumber, such as white pine, cherry, mahogany, etc., with very little waste.

As a resaw, this machine will rip by power feed, 10, 15 and 20 ft. per minute, [illegible] thick. As a scroll saw it will take 18 ins. under the guide, and will saw 38 ins. between the saw and the column. Saws from 18 to 20 ft. long and up to $2\frac{1}{2}$ ins. wide may be used.

The change from resawing to ordinary band sawing is instantly effected by swinging the arm carrying the two



GRINDER ARRANGED FOR GRINDING THE BOURLETTE ON 15-MM. SHELLS.

power-driven corrugated rolls out of the way and changing saws.

The frame is cast in a cored form, and has a base 46 x 23 ins. The floor space needed is 60 x 47 ins. The table is 40 x 36 ins. and 40 ins. from the floor, and tilts 45 degs. one way and 5 degs. the other. It is heavy, double-ribbed, and is supported on rockers for angle adjustments. The tilting is done by means of a worm gear and hand wheel at the right of the operator. The rockers are machined all over and tongued and grooved firmly to seats. The angles are indicated in degrees, upon the dial at the front of the machine.

The auxiliary table is 21 x 22 ins., and is bolted to the frame. It increases the surface of the work table almost half. It is vertically adjustable.

The wheels are of cast iron, 38 ins. in diameter, are machined all over and are given a running balance. Best quality leather bands are cemented to wheels. Upper wheel guarded with heavy wire mesh door supported on cast iron hinged bracket attached to column of machine. The lower wheel is enclosed in a metal casing having two doors. It is provided with a device whereby the dust is collected and thrown to the front of the machine for convenience in attaching an exhaust fan. The upper wheel is carried in a long split box lined with genuine babbitt. End thrust is taken up by end collar.

The outboard bearing supports the end of the lower wheel shaft and is self oiling. The tight and loose pulleys are located between this and the main bearing.

Saw tension is secured by a telescope spring of correct strength and elasticity, automatically adapting itself to the varying tension required for light or heavy saws. It is very sensitive.

The guide post is made of steel 1½ in. square and counterbalanced by an encased coil spring. It is readily locked to a fixed position. The post carries a frictionless roller guide, adjustable for varying widths of saws and another similar guide is located below the table.

A grooved saw guard is located on the column receiving the saw and protecting it both sides. A front guard made of steel with a wood facing is carried on the guide post and covers the saw above the blade.

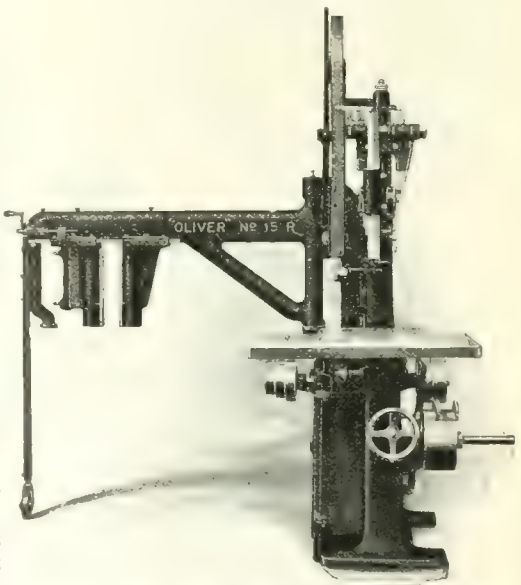
## JAPANNING IRON AND STEEL

By L. E.

The process of japanning iron and steel castings is not by any means a difficult process, providing reasonable care is exercised and that the operator has had some practice. The castings must first be dressed and all the sand and dirt removed, preferably by dipping them in a pickling solution, after which they should be well coated with good linseed oil. When the surplus oil has run off, the castings must be put into a slow closed oven and gradually heated till the surface is quite black. Should the oven be too hot the work will be spoilt by blisters, but to be of the correct heat when taken out the castings should have a fine black polish.

Another method of imparting a deep and beautiful black to iron and steel is to impound the work in a mixture composed of ten parts of saltpetre to one part of black oxide, but this mixture must first be heated in a pot until it is hot enough to char a piece of wood. This process is, of course, only used for machined and finished work, and this must be carefully cleaned first. There is, however, some disadvantage in the use of a heated chemical mixture for tempered steel, as the temper is sometimes drawn. Blacking iron and steel is sometimes done by first making the work brown, and for this a chemical solution, consisting of sixteen parts of alcohol and one part of corrosive sublimate, is used. After being cleaned the piece of iron or steel is washed with lime, then scrubbed with dry lime, as there must be no grease left upon it. It must not be touched with the hands. Rust plays an important part in the process. A sponge must be used to apply the chemical solution, after which the piece of work being treated must be put in a dark place to rust. This may bake anything from a few hours to several days, according to the conditions existing. When dry the rust must be carded off, and then another coat of solution put on, and the process repeated until the required brown is obtained. To change the brown to a permanent black the part should be put into a steam-heated oven for a few hours.

A simpler, but not quite so good, way of changing the color from brown to black is to simply dip it in boiling water, and before it has cooled to give it a coat of boiled oil. Sometimes instead of blacking or browning metal it is desired to make it blue, and this is not done by

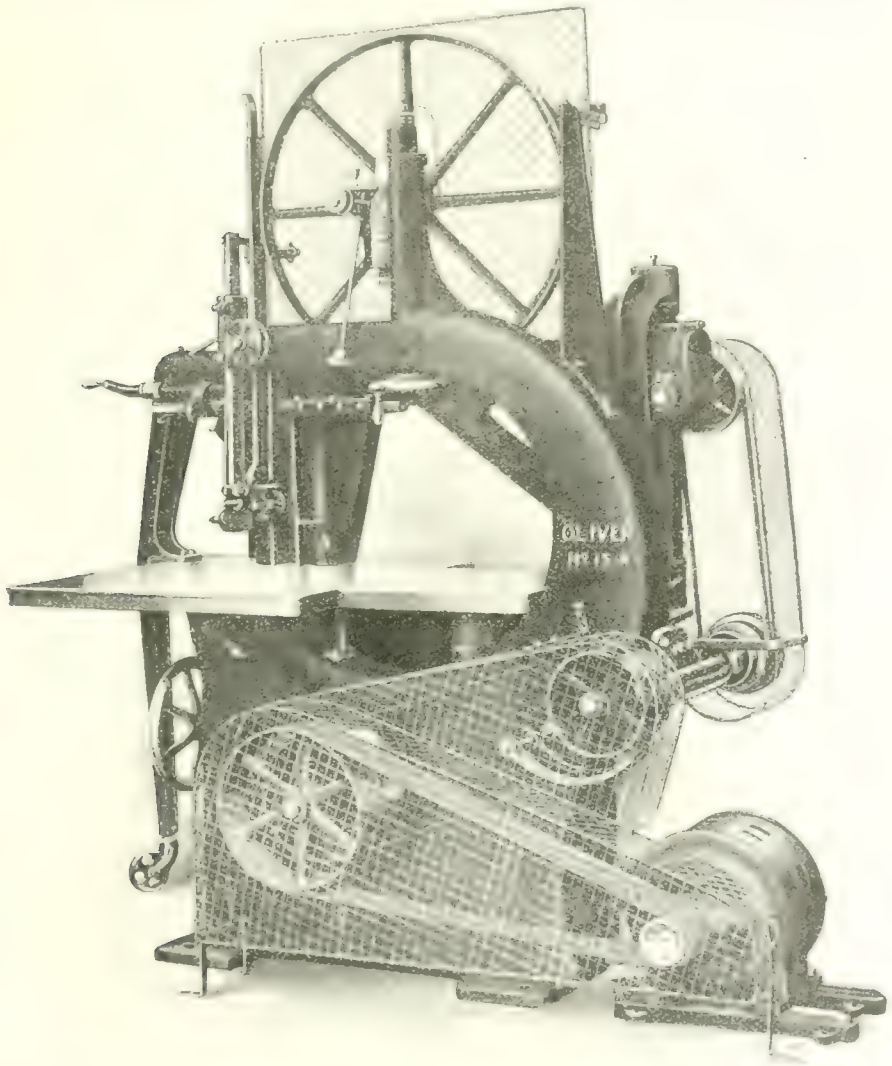


BAND SAW WITH RESAW ROLLS SWUNG OUT OF THE WAY.

dipping, but by heating it in charcoal or hot sand or wood ashes. Whichever agent is used is put into a pot over the fire, so that every particle may be evenly heated. It is stirred all the time it is put on the fire. The metal work will have to be hung by wires while it is dipped in the heated sand or ashes, and care must be taken that the work is absolutely clean and dry and highly polish-

ed. In bluing or blacking work the higher the polish the better is the result. Usually charcoal is used if a dark blue color is wanted and ashes or sand if a light blue color is wanted.

All sand and dirt should be removed, even from castings and forgings that are not to be colored, to save the cutting edges of the tools. Dilute sulphuric acid is a convenient and is also the commonest pickling solution, and a lead trough



BAND RESAW WITH WIRE GUARDS

makes a good pickle bath. It is a very easy matter to make a contrivance over the bath from which the castings can be suspended. The acid really melts the rough surface of the work sufficiently to lossen the dirt, when it is more easily brushed off. To secure direct action on the sand hydrofluoric acid can be used in the proportion of one part to ten parts of water, and it acts much more quickly than sulphuric acid.

## THERMIT

IN the process of melting aluminum by means of the thermit process the slag represents three-quarters of the contents of the crucible and, for the present at any rate, has to be thrown away as useless. Attempts have been made to convert it into a refractory but without success. Thermit products are restricted to the rarer kinds of metals and alloys which cannot be produced readily by ordinary fuel methods. Prior to the war the various compositions necessary for working the process came from Germany, but now that the company has been brought under entire British control, means have been found for producing everything that was formerly produced from materials of German origin, from materials obtainable in this country. This result has necessarily involved a great deal of research, but it has been successfully carried out, and there are now some thirty metals and alloys dealt with in this way. As has been known for some time, the Germans have made use of thermit in connection with incendiary bombs dropped from aircraft, and generally thermit is now a recognized military store. The thermit process for melting metal cannot, of course, be recommended on the score of economy, but where it is necessary to do so quickly in circumstances in which time is more important than cost, then it has an important place in industry. The use of the process for ship repairs and similar work during the war has been invaluable, and it is now a common thing for ships to carry a thermit outfit on voyages.

## CARBORUNDUM

The discovery of carborundum is due to Dr. Acheson, of the United States, who, following up some early work of Moissan, discovered that hard crystals were deposited after passing a current through a mixture of salt and coke. The first sale of this material, which was to a jeweler, was made at the price of £175,000 per ton, the output being at first four ounces a day. As the use of the material for grinding became known its output increased, and the price dropped to £2 per pound, then to one guinea, and later to 2c. per pound. Carborundum will not always successfully deal with steel, with the result that a harder material, alundum, or aloxite, had been introduced for this purpose. It is produced by fusing bauxite, the most important deposits of which are in the South of France, although there are some in County Antrim which are of uncertain composition. The material is produced at the mines and sent to the works of the Carborundum Co. at Manchester, where it is made into various grinding stones. The Norton Company, of Canada, also owns some American deposits of bauxite. Alundum has also been found to act as a good refractory, having a melting point of 2,050 deg. An interesting feature of its use in the electric furnace is that if a silica muffle is wound with platinum wire the wire will not stand the high temperature, whereas when wound round an alundum muffle it will. Alundum is porous and is used as a filtering medium.

## MECHANICAL SKETCHING AND DRAWING

Continued from page 604.

situation will be described in detail in another article.

Dimension lines (E, Fig. 10) will, in this series of articles, be shown as broken lines comprising a series of very short dashes which are almost short enough to be dots. In many shops it is the practice, and, in fact, it is universally considered good practice, to make dimension lines very fine, unbroken black lines. However, where drawings must be reproduced for cuts, a dotted line gives more contact and is hence more readily understood than a fine unbroken line.

Arrow heads are used on the ends of dimension lines (E, Fig. 10) on the ends of section lines, as at F, and for other purposes. The arrow heads should always be bold and big enough so that they will be quite legible.

### HISTORY REPEATS ITSELF

INDUSTRIAL developments in the United States, due to the increasing pressure of war conditions, have served to strengthen the advocates of equal treatment for male and female workers.

When the dilution of labor first commenced in Great Britain, the hide-bound traditions of trade unionism sustained many a severe jar resulting from the undiluted sincerity of women workers in doing their best. When the United States entered the war, it was not at once realized that women might be called on to help as they had been in Europe, but circumstances are demanding it, and the good showing of their English sisters has been largely duplicated by American women.

The appalling shortage of skilled labor in the States is perhaps realized by a few only. It is not that there are not many hands, but the capable hands are few while the jobs are many. The council of national defense through the chairman of its section on industrial training for the war emergency states that of 10,868 skilled men who applied for jobs in one district during one month, only 1,200 were found to be competent machinists. An average of 10 per cent. only of all applicants where the work demands skill have been found usable without training.

Not only is good instruction difficult to secure but care has to be taken to prevent many learners absorbing undesirable and inefficient methods of working.

While such a condition can be remedied in time and by concentration of effort, the problem of reconciling a large proportion of the men to the newcomers is much more difficult of solution and meantime operates against the war effort of the nation.

Two instances indicate the change of spirit which must be effected: in a certain shop a girl made $9 a day almost from the start because a man who operated the machine before her had satisfied his employer that $5 worth of work was all that could be produced—again, male workers in another factory turned out 20 pieces per hour of a certain fuse part, where as a result of a price dispute the men had greased the belts, etc., and cut it to 12 per hour. Women were trained for the work and ultimately raised the output to 55 per hour.

The mention of price dispute touches on a feature which has done much injustice to male workers in general. The only conditions which will result in maximum output from men are absolute honesty and sincerity on the part of the employers so that the men will trust them in all of their dealings. There is no use in blaming it on the men; most of them have been stung once, and they must be shown now more than ever before that reasonable effort on their part will not react to handicap and overload them while the employer makes war profits.

If a firm has accepted a contract, based on certain existing shop conditions, and then through patriotic and other methods induces the help to become more efficient, the help must share accordingly. Perfect frankness must accompany any proposed reduction, and the suggestion has been made that a committee of employees should act on behalf of the shop hands and be informed and consulted where a reduced rate is obviously reasonable where conditions have been brought about by the firm's initiative and at their expense.

On the other hand a maximum rate might well be arranged with the men, a rate which all might not hope to reach or even be capable of reaching, but which some brighter minds might attain through extra effort or resource. A liberal bonus system for such employees, rated according to increased results obtained would do much to stimulate effort and remove that distrust which in these days is one of the enemy's best weapons.

### NATIONAL CONCENTRATION

ALMOST four years of warfare have removed most of the national hesitation, nervousness, indecision and ignorance which came to light occasionally as the tide of fortune ebbed and flowed in the great struggle. Periods of elation and depression have alternated. When the United States entered the war spirits ran high, to gradually subside awaiting definite accomplishments by our big Ally.

It was presumed by many, that, having the benefit of British and French experience, plus American hustle, things would be doing soon. Despite the disappointment experienced by those expectant enthusiasts, the work of the States during the last year has been on a colossal scale, characterized by a deliberateness of action and actuality of accomplishment which in days to come will be more than ever appreciated. Treachery and treason are best dealt with silently.

The increasing importance of the United States forces, due to the rapid growth of numbers and the development of home sources of war supplies, is of particular interest at this time. Not the least interesting phase is the publicity given to actual accomplishment, and the calculable effects of real facts on the morale of the enemy is probably one reason why such work is given special attention by the authorities at Washington.

An announcement by the Shipping Board shows that one wooden ship per day has been turned out for the past few weeks and steel vessels are being delivered almost as rapidly. In noting this fact it should be observed that one factor has been the overcoming of the lack of transportation. A great speeding up in the delivery of cars for transporting shipbuilding materials is reported by authorities and what has been done in respect of this industry will doubtless be accomplished for the rest of the country's activities in proper rotation.

### WELSH TINPLATE SHUT OFF

ONE of the shifts in trade occasioned by war conditions is the shutting off entirely of Welsh tinplate from the Canadian market. "Hardware and Metal" states that an arrangement has apparently been reached between Great Britain and the United States to the end that the United Kingdom would cease to ship tinplate to countries to which the United States is now exporting.

The output of the Welsh mills has been greatly curtailed since the outbreak of war. Last year the output was estimated at 350,000 tons compared with 825,000 tons in 1913. The British output is taken up for munition requirements for herself and some of the Allies, for the Board of Agriculture and Fisheries, the Ministry of Food, the Railway Executive Committee, the High Commissioners for Australia, South Africa, New Zealand, the crown agents for the colonies and the Egyptian State Railways.

It will be seen that with the decreased output of the Welsh mills there is quite a sufficient demand from other sources to forego the Canadian trade in favor of United States mills. The United States will also supply South America and the East with tinplate.

# WON HONORS FOR HIS WORK AS LIFE SAVER

**Robert Hugh Nichol Has Been With Well Known St. John Firm for Almost Forty-Four Years.**

ALMOST forty-four years ago, Robert Hugh Nichol, after a public school education, entered the shop of T. McAvity & Sons, at St. John, N.B., and he has been there ever since, working his way up to the position of foreman of the brass works on Water street.

His experience is that of many others who have come to hold positions of responsibility in firms in Canada or elsewhere. CANADIAN MACHINERY, during the last few months, has succeeded in coming into contact with a large number of men who are now foremen or superintendents in Canadian plants. Their experience is interesting. It bears out what Mr. Nichol has found from actual experience, viz., that a boy with only a public school education soon finds out that it's up to him to start in and study as soon as he begins his trade. Otherwise he is not going to be much of a success.

ROBERT HUGH NICHOL.

Mr. Nichol was born at St. John, in 1861, the son of a pattern maker on ship work. He received the common school education offered to the boys of his day, and before the age of 14 he entered the McAvity shops as an apprentice, serving five years at that training. It is well worth recalling, by way of comparison with present day wages, that the apprentices of forty-four years ago accepted the scale of $1.50 a week as a matter of fact.

Finishing his apprenticeship in the brass business Mr. Nichol continued with the firm, and kept up the studies and reading he had undertaken. His promotion to the position of superintendent followed.

Athletics have always appealed strongly to Mr. Nichol, and he has been connected with a number of organizations of a public character. For instance he was with the 62nd Fusiliers of St. John and had the rank of sergeant; was for 20 years connected with the St. John fire department, joining in 1885. During that time he won the hook and ladder race with competitors from all Eastern Canada and Maine, U.S.

### For Life Saving

Probably one of the most interesting incidents that could come into any man's life was the one that resulted in Mr. Nichol's receiving a gold medal from the late President McKinley, of the United States, as well as a bronze one of the Royal Humane Association for conspicuous bravery in saving life at the imminent risk of his own. This happened almost at the close of the year 1899, on the second day of December. The schooner Hazel Dell, a U.S.A. boat, got into difficulty so serious during a storm that she was wrecked off St. John. Mr. Nichol, when volunteers were called, was one of the first to jump into the boat that pulling out to the rescue. The trip was a hard one in bad weather, and the volunteers had a hard time from exposure and cold. The subject of this sketch has always been an expert oarsman, and that stood him in good stead. Apart from the recognition mentioned above he received a letter of appreciation and a gold piece from the city of St. John.

In following his work in the brass business, Mr. Nichol has shown considerable ingenuity and initiative, and has invented and perfected numerous tools and articles for brass workers.

"I would strongly advise the young mechanic and apprentice to keep in close touch with technical papers, etc. In this way he can keep posted as to the latest development, and the methods and devices that are being employed by men all over who are really doing and accomplishing the worth while things." That is the way in which Mr. Nichol views the value of trade and technical papers, and he is not backward in starting the value he attaches to them.

## You Know Some of These Chaps

> Sir John Foster Fraser, chairman British National War Lecture Committee:—"Kerensky failed because he talked and talked, and talked—the characteristic Russian failing. He had committees and meetings, and committees are the curse of real progress."

By heck I know a heap of folks what's bent in that way, too; they're always lookin' for a chance to wrangle and to chew—to them it is a joyful thing to grab some helpless wop—and make him open up his lug to drink in all their talk.

What always strikes me 'bout these kind of folks what speak of this and that, is that 'bout nine times out of ten they're hollerin' through their hat.

There's lots of them most every day a-clamberin' on a stump, and smitin' at the atmosphere with one terriffic thump—to tell us what things should be did, and what things should be said, you'd think they soaked up knowledge from the feet clean to the head.

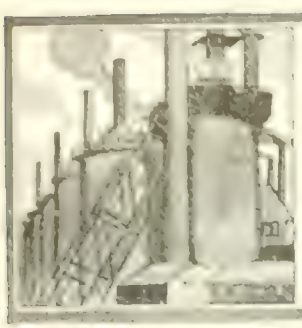
They know all things there be to know of metal, iron and steel; they know about the monkey wrench, likewise the drivin' wheel.

They know what's wrong about the war, by heck they make me sick; I'd like to smite 'em with a rail and whack 'em with a brick—they like to stick their thumbs inside the corners of their vest, and then to squirt ten yards of talk from somewhere 'neath their chest.

There ain't no peace when they're about, no time for thinkin' deep; they're simply always rantin' round somewhere on top the heap.

I'd like to go to them there folks and speak just what I think, and tell 'em that their domes is bent and sadly on the blink. I'd like to go and tell 'em that a lot of folks was prayin' for them to close unless they had a thought well worth the sayin'.—ARK.

Not so many years ago real estate men used to be fond of telling of money that they might have made. They rolled under their tongue with great satisfaction the fact that they might have bought lots at ten dollars a foot and worked them off on some other lobster at fifty and sixty per inch. To-day much the same wails of regret come from other lines. Tin sells to-day from $1.25 to $1.30 per lb., while not so many months ago it was trading around thirty cents. Pig iron used to meet the old Buffalo price of $12.80 per ton, but at present the seller with a pen of iron pigs can pull down four times that amount. Plating chemicals now cavort at two, three and four times the old lists, while high speed steel is on a double and plus list on top of that. So when it comes to speaking of prices that were and prices that are the real estate man is simply going to get elbowed off the edge of the platform.



# MARKET DEVELOPMENTS

## Non-Ferrous Lines Don't Feel the Pinch As Much as the Steel and Iron Trades

### Firms Still Able to Secure Their Supplies in Good Volume—Boiler Tubes of the Two-Inch Size Are Practically Off the Market—Sharp Rises in Plating Supplies

CANADIAN dealers, although they are not talking of it yet, may be figuring what the freight increases in United States are going to cost them. Steel will probably feel the increase more than any others in the group, on account of the volume of it moving, and for another reason not so apparent. There are almost five tons of raw material represented in a ton of the finished article and the haulage on all these primary ingredients will figure against the finished product.

Boiler tubes of the two-inch size are badly needed in Canada. It may be that a shortage of help keeps production low, but whatever the reason, the fact remains that the situation in Canada right now is correctly described as "acute," for the sizes needed in repairing the average locomotive and stationary boiler are almost off the list now. The average threshing outfit boiler uses the two-inch type.

Canadian plants in several cases are turning over their shops to new shell orders. In some circles there has been a tendency to make it appear that new munitions business coming to Canada was a clear gain to the volume of material being turned out, but this is not the case. Some plants will simply wind up British orders and turn to American business, so in reality such a change will represent no increase at all in the actual volume of business being done.

Pig iron is in great demand and the supply to keep pace is not forthcoming. Prices are four times the figure at the outbreak of the war. Nor is the right kind of scrap material forthcoming in large enough quantities to help out the situation.

Carbon and high speed cutters, drills, etc., are firm and still on plus and double lists. Prevailing price lists on valves are withdrawn, pending a new price announcement, with prospects of an upward tendency.

A Toronto dealer in a position to know the facts estimates that there is not much over 25 tons of available tin in the country at present. Tin used to trade freely at 20 to 30 cents in pre-war days. Now a man with tin to sell can be certain that bids will start at minimum of $1.25 per pound. and may go higher, depending on the urgency of the sale. Other non-ferrous metals are firm. For the most part industries depending on these as basic materials are faring better than those which enter the steel and iron market for supplies.

Demand is brisk for machine tools and supplies, there being no signs of a cessation from this condition.

## MONTREAL IS STILL A VERY BUSY PLACE WITH MUNITIONS BUSINESS

Special to CANADIAN MACHINERY.

MONTREAL, Que., June 4.—Recent announcement to the effect that a new large shipbuilding plant would be commenced immediately in the vicinity of Halifax does not come altogether as a surprise as negotiations to this end have been under way for some time. This new enterprise which will be known as the Halifax Shipbuilders' Limited, expects that the expenditure will be approximately $3,000,000, and the only connections with the government will be that this body guarantee the placing of capacity volume of tonnage. It is anticipated that the first vessel from this yard will be completed within a period of about fifteen months. Munitions production goes on apace, and the activity in this industry has been further accentuated by additional orders from the States. Rapid progress is being made by several Montreal firms in the completion of plants for recently received contracts and equipment is being acquired as rapidly as possible. Darling Bros. have started to excavate for their new iron foundry which is expected to be completed this summer. Apart from activities directly connected with war essentials, general business of an industrial character is very quiet.

### Steel

With the near approach of the hot weather steel dealers are anticipating a little greater difficulty in obtaining materials owing to the established fact that such conditions affect the output from the mills and furnaces. With the present requirements constantly increasing, any serious reduction would have a corresponding effect upon the manufacturing industries and the existing pressure would be still further emphasized. As reported by a local dealer, one of the great difficulties under present conditions is the inability to state definitely just what volume of steel will be required for American war purposes during the coming months, and this uncertainty tends to maintain the demoralization in the ordinary demand that has been virtually nil for several months past. While the greater number of mills are devoting their entire production to government needs, it is also true that in some instances stocks are gradually being accumulated, but the producers are reluctant or unable to dispose of these until it is definitely decided just what quantity of steel will be required for government consumption. Canadian consumption at the present time is practically confined to war requirements, and little steel can be diverted to ordinary domestic purposes. This applies in particular to material coming in from the States as the license necessary for delivery of steel makes it almost impossible to secure material for other than war essentials. The declining tendency that was noted in the plate situation a couple of weeks ago had little effect on the market here as dealers reported that the lower price had little to do with the action of the market, as the existing movement in steel was confined to war requirements exclusively, so that price

changes were of little account when no steel could be obtained. Local quotations have, however, been again advanced to the previous level, but the market is unchanged.

### High Speed Steel

The increased activity in the shell industry and also that of machine tool construction has been reflected in the additional demand for high-speed steel. Local dealers report considerable activity in the demand for the larger sizes of steels to meet the requirements for the heavier shells. One local dealer said that less difficulty has been experienced in obtaining this particular grade of steel from points in the States and intimated that some provision might be made in the near future whereby increased quantities could be obtained from England. Quotations range from $2.00 to $2.25 per pound.

### Metals

The general metal situation has taken on a more settled tone following the announcement of the War Industries Board in the States regarding the fixed price of copper for the ensuing period. The action of the board in this respect has apparently removed some of the nervousness apparent a week or so ago and transactions during the past week indicate greater confidence on the part of the trade generally. Copper is more settled on the reaffirming of the previous fixed price. Tin is still very strong but an easier tone has developed. An undertone of strength is shown in both lead and spelter. Antimony is unchanged, with aluminum tending to a higher level.

**Copper.**—The decision of the American Government to retain the previous fixed price for the sale of copper during the ensuing three months has not come as a surprise to the greater proportion of the trade although there are still those that appear to think that a higher price should have been established. Probably a higher price might have been an inducement for greater production but the present output is apparently sufficient for all essential requirements, and as these are virtually absorbed by the government this body probably figured out that the additional price would necessitate greater outlay without materially altering the actual conditions. Local demand is steady, but the market is unchanged with prices firm at 29 and 30 cents per pound.

**Tin.**—This metal is still retaining the interest of the market, but recent advices appear to indicate that a weaker tendency will develop in the near future. Little surplus metal is available but the London market is gradually declining and the prospects for increased supplies on this side are brighter than for some time. However, the situation is still acute and dealers here do not look for a speedy change but anticipate a gradually adjusted market to a lower price level. The local market is still strong but dealers are asking prices that show a decline over last week of 5 cents per pound. The nominal quotation is now $1.30 per pound.

## POINTS IN WEEK'S MARKETING NOTES

**A record for ship production was made in United States yards during the month of May.**

**Coal shipped from United States producers that is not clean can now be turned back at the expense of the producer.**

**Business pending in United States for machinery for war purposes will run into $100,000,000, and the next 60 days will probably see the most of the deals closed.**

**U.S. Ordnance Department is in the market for 310 lathes from 18 to 32 inches.**

**It is hard to say what effect the U.S. freight rate advances will have on iron and steel prices. In a ton of steel the freight on almost five tons of raw material comes into consideration.**

**Firms who rely on the non-ferrous metals as their raw material are not feeling the war pinch nearly so much as those using iron and steel.**

**Boiler tubes of the two inch size are a very scarce article in Toronto and district, and are needed for repairs to threshing boilers and stationary and locomotive boilers.**

**One Toronto firm placed an order this week for 700 eighteen-foot lengths of 3½-in. tubing for repairs, and dealers are hopeful of it passing the war board.**

**One dealer estimates that the available supply of tin in Canada at the present time is not over 25 tons.**

### Machine Tools and Supplies

The demand for machine tools continues in a very encouraging volume as a result of theh revival in the shell industry created by the additional placing of American munitions contracts. While the general requirements for tools are generally for the special designs of single purpose machines, dealers report considerable enquiry for standard equipment, a great deal of this being caused through the inability to get delivery in a reasonable time of the tools they desire. Many machine shops in this district are actively engaged in the construction of special tools for the different size shells that have recently been placed. Owing to the abnormal requirements for machine tools of every description shipments of machinery from the States is very indefinite and few dealers are able to give a reliable date for delivery from American tool builders. Work for the new factory for Lyall's is well under way, and orders for the necessary equipment for the 155 m.m. shell have been let; about 100 of these are being manufactured by the Robt. Gardner Co. of Montreal. The entire equipment for the 155 m.m. shell plant of Caron Bros. has been ordered; H. E. Streeter, for the Swedish Gage Co., placing the requirements for the gage standards. Dealers report a very brisk business in all classes of machine tool accessories and shop supplies.

### Scrap

The old material situation has the appearance of being quite unsettled owing to the evident uncertainty that prevails in the market. Considerable activity is shown in various lines, particularly in the demand from the foundries for cast iron scrap, this demand being created from the blast furnaces. Heavy melting steel is in demand but generally the dealers handle little of this owing to the fact that the same is utilized by the shell plants themselves or is shipped direct to the billet-making foundries. Aluminum scrap has a stronger tendency, but scraps with tin and lead in their make up are showing a declining tendency. Local prices are generally firm, but the market is comparatively quiet.

## THE BOILER TUBE SITUATION ACUTE

**Market Is Practically Bare of the Two-inch Size—Large Amount of War Business Offering**

TORONTO.—Although commercial orders are being discouraged by the War Board, by the dealers themselves, and practically by every person who is trying to give priority to war orders, indications are not wanting that there is a good amount of this business piling up against the day when the barriers against it shall be let down. As a matter of fact there are commercial lines that are very closely allied to the war, and to the safety of the individual in the meantime. One Toronto concern is in the market this week with an order for well on to a thousand 3½-inch boiler tubes of the eighteen-foot length. There is a good chance of this order being passed by the War Board, as it is for the repairing and upkeep of power and heating systems. But the boiler tube situation is now at the state where it can be correctly be described as acute. The warehouses are practically bare of the two-inch size, and this is the type used very largely in the average boiler, the locomotive, threshing boiler, etc. There are many cases, so we are informed, where tubes are needed to make necessary repairs, but those wanting them are meeting with no success at all in having their needs attended to.

A man with pig iron to sell in Canada at the present moment would hardly need a selling organization or an advertising campaign to help him out, for a needy industrial world would beat a path to his door. The call incessantly is for pig iron and more pig iron. The Muni-

on war orders. Substitutes that are iron pile are not to be had in appreciable quantities, the yards being quickly stripped of any offerings that come their

will have on the price of pig and steel coming to Canada from U. S. points. Of course it will be reflected in the price of steel more heavily than in the case of iron. In a ton of finished steel it is required to move almost five tons of raw material to the furnaces, while in the case of pig the amount of basic ingredient is not nearly so great.

The tin market is gradually working into a smaller groove, and trading in it still continues to be a case of making the best possible bargain with the man who has some to sell. One dealer, who is in a position to speak on the matter, stated to CANADIAN MACHINERY to-day that he did not believe that there could be much over 25 tons of tin in the country at the present time.

### The Steel Situation

Some idea of the congestion that took place last winter in the transportation and delivery from the mills can be found in shipments that are coming forward this week. One warehouse in Toronto took in plate to-day, orders for which were placed in the last months of 1916. Orders that are being placed now are making fairly good time. The prices that went to a higher level last week remain at the new figure, and are likely to do so for some time. Staybolt iron advanced ten dollars per ton to-day. The price for this has been firm at $8.50 per hundred for some months, there being always a good demand for it, its high-grade being relied upon for use in heavy chain work, etc. The boiler tube situation is not improving. "We are not getting any twos at all," stated one dealer to-day, "and there are many cases where it is highly desirable that this size should be supplied. Threshing outfits and a great many locomotives and stationary engines use that size. The larger ones can be had." One Toronto house ordered 700 18-foot 3½-inch tubes for repair work to-day, and the expectation is that the order will be passed by the authorities at Ottawa.

There is a keen demand for plates, the shipbuilders using a large tonnage at present. There is always a fairly brisk demand from the yards for plates to take the place of "rejects" that are found in the shipments, and it is necessary that they should always be able to get these on the shortest possible notice. Apart from the staybolt iron price, no other fluctuations are recorded this week locally.

### Second-Hand Metals

There is hardly an interesting feature in the used metal market this week. Prices have not changed since the last letter a week ago, and in many ways there is a feeling of dullness and near-stagnation over the entire business. Just now there are movements under way by which large amounts of non-ferrous holdings may be released for domestic orders. If these go through, the yards here will be in a position to restock, and may be keener to take on business. At present they will buy what is offered at strictly current quotations, this being necessary to protect their credit, but they are not anxious to take on any more material that cannot be turned over to the war appetite establishments.

### Tools and Supplies

There is still good business being done by men who have lathes of the heavy type for sale. Other machine tools are in demand, and a large amount of business is turning in both new and second-hand machines. There is a tendency in some parts to take it that the new munitions contracts that have been handed out will create an immense amount of new business. This is not altogether true. It means that many plants are "turning over" rather than starting at the beginning. They will be simply making another size shell and dropping orders that are now nearing completion. In this process there are cases where new equipment is needed, but there are others where only a tooling up is needed to make them ready for business, so it is hardly fair to imagine that every mention of new orders for shells means a new plant and new business for the machine tool men. There is a brisk demand for carbon and high speed goods. Prices keep firm. As a general thing carbon goods are 60 on the list now, while the high speed is two and a half times the list. An order was sent out, becoming effective on the first of June by which prevailing lists on valves are cancelled, pending the issuing of a new list. Prices generally are ten on the list now, but the withdrawal of the old lists is taken to forecast an increase which dealers anticipate will run the new price well on to 35 on the list. Chucks are scarce in some places, particularly the 9 to 12 size, and there is always more or less delay in getting permits to bring them across the border.

Firms operating on lines that depend on the non-ferrous metals for raw material are not yet feeling the war pinch to the same extent as those using iron and steel, which come more directly under the notice and control of the War Board. As long as the supply lasts there seems to be no disposition to hold it up. Tin is scarce. There's nothing new in that statement, but it is becoming increasingly scarce. There are not over 25 tons in the country just now, according to one dealer who is in a good position to judge the situation correctly. About the time the war broke out tin used to trade around the 25 to 30 cent. mark, but now a person who has tin to sell can start the bids at $1.25, and work from there up. Lead is slightly firmer in tone and a slight price advance was recorded this week.

# PIG IRON VALUES HAVE JUMPED OVER THE MOON IN RECENT YEARS

Inquiry among men who are in the steel business as producers or as jobbers fails to bring out many opinions favorable to the plan of the Canadian government, whereby a three year output will be taken from any new producer of pig iron in the Dominion.

It will be remembered that a deputation, or several of them, had been in Ottawa from British Columbia, urging that a subsidy should be given to the producers there in order to develop the pig iron business in that country, where the iron ore, coke and lime are to be had.

Rather than pay a bounty the government announced that it was willing to enter into a contract with any of the producers who would put in smelters, and take over their output for a period of three years.

"If that satisfied the people of British Columbia," stated a well known steel CANADIAN MACHINERY they are very much more easily satisfied than I had ever reckoned on in the past. It is possible that I may be mistaken, but it looks to me as though the government had handed them a blank. What is the use of telling men to go ahead and produce pig iron and assuring him of a market for a three year output, when such a market is already assured? It will take a long time before there is enough pig on the market to make it necessary for any assistance to be given in selling the output."

Pig iron is pulling down fancy prices just now. Many of the dealers are fond of harking back now to the days when the producer in Canada had to meet the old Buffalo price which used to hang around the $12.80 mark. The experience of one Toronto dealer, as told to this paper is interesting. He was figuring out his gains—on paper—on a deal that never went through, because the mills have never poured out his order for him.

"It was in 1914 that I placed an order for a thousand tons of pig at a Canadian blast furnace," he stated. "The price then, according to the records I was looking up to-day was around $16.25, and that was considered a very fair figure, as the prices had not yet commenced to climb. Well, they never came to that order, and now the priority of strictly war business has placed me on the indefinite waiting list. But the price of that pig to-day would be—well not far from about $66.25 a ton. Don't you see where I would have made $50,000 by buying then and selling now?" he laughed, and the reporter had to admit that it was a very simple matter to build up fortunes, especially on paper.

# SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

## PIG IRON

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5, 6 and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

**64 Front Street West - - - TORONTO**

# CLEAN COAL OR IT WILL BE RETURNED

**New Order of Things to Provide the Supplying of Good Material to Consumer**

Special to CANADIAN MACHINERY.

WASHINGTON, June 3.—President Wilson's address to Congress this week, calling for new revenue legislation, has been interpreted as notice to business in the United States that it must bear the burden of additional taxation. The new bill will be particularly aimed at those persons and corporations which are making large profits out of war work. President Wilson has also called upon Congress to deal with "profiteers." There is evidence in the various Government departments that certain individuals are taking advantage of the crisis which faces the nation and are using it to amass large profits. Special investigations will be undertaken by Congress to learn who these parties are and what interests they represent and the penalty for "profiteering" will be heavy taxation, and it is also the plan to attempt to secure additional criminal legislation which will put a stop to the practice.

### Raise in Rates

Another event of importance to business in the United States and Canada [illegible] has been the announcement by Director-General of Transportation McAdoo of new railroad rates. Passenger rates are raised, but this will not affect seriously the work of business. Increases which have been made upon freight rates, however, have aroused the business interests and already protests have been made to the Director-General. An increase of twenty-five per cent. has been ordered on all class rates. The same increase applies to commodity rates [illegible] In the cases where commodity rates affect a commodity which is shipped in large quantities. In those instances the increases are graded. Increases on coal have been ordered which run from 15 to 50 cents a ton; coke, 15 to 75 cents a ton; iron ore, 30 cents a ton. All of these rates will be subject to the review of the Interstate Commerce Commission and it is very likely that hearings will be held when those affected may present their arguments against the increases. Business all over the United States and Canada will be made to bear the burden. Another order issued by the Railroads Administration will also seriously affect the business interests of both countries. This order provides that there shall only be cash transactions with the railroads in the future. In the case of freight, however, under special conditions credit is extended for forty-eight hours.

### A Record Month

The month of May has been the greatest ship-producing month on record, according to reports from the United States Shipping Board. During the month the launchings have averaged more than two ships a day. For the week ending May 25, there were ten steel vessels launched with a total tonnage of 63,486. Eight of these were requisitioned ships and two were ships which were contracted for by the Shipping Board. The total ship production for the week was 109,700, which included wooden, composite, steel and concrete vessels.

Under the direction of Charles M. Schwab, the newly appointed head of the Emergency Fleet Corporation, that Government department has been moved to Philadelphia. In the future the actual work of directing ship construction will be directed from Philadelphia. Plans and policies and general administration work will still be done in Washington, however, by the United States Shipping Board, with Edward N. Hurley as chairman.

### Ship Clean Coal

Coal production in the United States has fallen off during the month of May. This is partially due to a shortage of cars and partly due to the lack of labor. The Fuel Administration is nevertheless hopeful that the production can be maintained at a point which will insure the nation's business against any recurrence of the serious coal shortage of last winter. As an aid to industry the Fuel Administration is taking steps to enforce coal producers to ship clean coal only. Orders have been issued that coal which is not clean may be turned back to the producer at the expense of the producer.

President Wilson, by executive order, has created the War Industries Board as a special governmental agency. Under this provision the War Industries Board will no longer be an adjunct to the War and Navy Departments but will be a separate unit which will control the war business of the United States. Bernard Baruch, as chairman of the board, will become a virtual business dictator.

### Price Fixing

Prices have been fixed during this week on a number of mineral products which are essential to war industry. By an agreement between the producers, President Wilson has approved new fixed prices for zinc. The prices fixed are 14 cents a pound for plate zinc and 5 cents a pound for sheet zinc. A price of 33 cents a pound has been fixed on aluminum and manganese ore has been subjected to a sliding scale of fixed prices according to the quality. This sliding scale of prices for manganese runs from 86 cents a unit to $1.30 a unit. Efforts are being made through the fixing of these prices to stabilize the mineral industry in the United States so that there may be no shortage of minerals which are necessary to the work of winning the war and it is also argued that fixed prices will stimulate production. Steel manufacturers have complained to a considerable degree that their output has been hampered by a lack of manganese and because of widely fluctuating prices, owing to the fact that there is great competition for the available supply. The new fixed prices, it is believed, will to a large degree control this matter of competition for the supplies of manganese

# FIGURING OUT WHO PAYS THE INCREASE

**When Government Is Chief Customer the Chances for Lower Prices Are Increased**

Special to CANADIAN MACHINERY.

PITTSBURGH, Pa., June 4.—The joint committee of representatives of the war industries Board and the steel makers appointed May 17 is progressing with its work of determining the probable monthly steel requirements of the various war activities and the prospective supplies, but no information whatever as regards the nature of its conclusions is forthcoming. It is improbable, indeed, that anything will be made public except through the medium of such action as the War Industries Board may take upon receiving the report. This action may be in the nature of the board's taking over complete control of the allocation of all steel, but that is quite improbable and would occur only in the event of its being shown that there will be very little steel left after the direct war requirements are covered. It is more probable that the finding will be that in the long run it will not be necessary to divert to the war activities as much steel as is now being shipped in that direction, while the mills are operating under their 100 per cent. pledge of war efficiency.

It does not follow that there is any possibility of the steel left after actual war orders are taken care of being allowed a free movement to whoever desires it. Some measure of control is certain to be exercised, for nothing is clearer than that the Washington authorities regard the commercial requirements in steel as of widely varying shades of importance, with respect to the aid they may give indirectly towards

# ADVANCES HAVE BEEN QUITE SHARP

**Plating Chemicals Have Gone Sharply Up In Recent Weeks**

Foundrymen who are replenishing their stock of plating chemicals and supplies are finding that they are buying from a much higher market. This is especially true of ammonia products.

Ammonium sulphate was quoted a few months ago at seven cents per pound, while to-day the price is placed at 30 cents, an increase of over four times the former value.

Ammonium chloride is quoted now at 40 cents, while not long ago the selling figure was given at 11 cents.

White arsenic, another ingredient used in plating, now sells for 25 cents, being double the price at the first of the year.

Price increases in plating supplies that run only thirty to sixty per cent. are hardly worth making special mention about. So when the man who does plating begins to talk of high prices, don't talk back to him, or he'll floor you.

# THE A. R. WILLIAMS MACHINERY CO. LTD

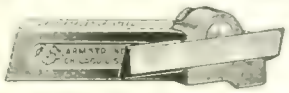
64 FRONT ST., W. TORONTO, ONT.

SALES SUPPLY DEPARTMENT SERVICE

# WHEN EQUIPPING YOUR PLANT

**"ARMSTRONG" TOOL HOLDERS**

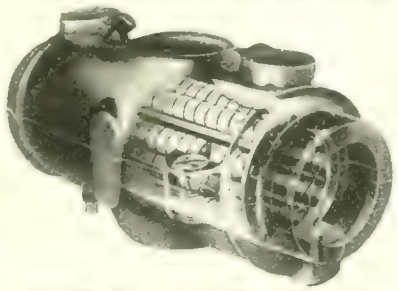
A complete line of these well known tools always on our shelves for quick service.



We have an Armstrong Tool oHler for every operation, Turning, Boring, Threading, Knurling, Cutting Off, Planing, Slotting and Drilling metals.

**"HYATT" ROLLER BEARINGS**

Friction in the transmission of power can be minimized through the use of the Hyatt Roller Bearing, the bearing of the highest practical efficiency. Hyatt, the economical transmission bearing, cost less



to install, does away with continuous expense in oiling. Being a split bearing can be put on anywhere or any time. Many installations throughout Canada speak for this bearing.

**do not overlook the fact that our SUPPLY DEPARTMENT is in a fine position to supply your every demand, including prompt service and right prices.**

**"MECHANICS" TOOLS**

## THE A. R. WILLIAMS MACHINERY CO., LTD.

TORONTO, ONTARIO

the control will originate with the War Industries Board and how much with the producers themselves.

It is likely to be a week or two still before the cost committee presents its findings. Steel cannot become scarcer, with the commercial industries, than it is now when the mills are operating under the [illegible] and it may become decidedly more plentiful. When the increased shipments to the war activities, and particularly the shipbuilding industry, were undertaken more than a month ago, it was the expectation of the mills that a few weeks of this intensive shipping would stock up the various activities and lead to a call on their part for a curtailment in shipments. There are no signs of such a call being made in the near future, but still it is believed that many if not all these activities are really receiving steel at a greater rate than is actually necessary.

### Production

Production has not increased materially in the past ten days, by reason of the extremely hot weather, fully as hot as is usually experienced in the hottest periods of summer. A fair estimate for May production as a whole is a 42,000,000-ton-a-year rate in pig iron and 44,000,000 to 45,000,000 tons in ingots, against capacities of at least 43,000,000 tons in pig iron and 47,000,000 tons in ingots. While these are large outputs compared with averages in 1916 and 1917 of about 39,000,000 tons in pig iron and 41,000,000 tons in ingots, yet if production of ingots in May were at the rate of 44,000,000 tons and in June at the rate of 45,000,000 tons, the average rate during the first half of the year would have been only 39,000,000 tons, so that the industry would have fallen far short of making up the deficit in production caused by the very light output in January and February.

### Advanced Freights

Freight rates are being worked out, to go into effect June 25 in accordance with Order No. 28 of the Railroad Administration. Generally speaking freight rates are to advance by an average of 25 per cent., and passenger rates go up also. The object is to overcome the increased operating costs and avoid drawing upon the Federal treasury to make good the earnings guarantee to the roads under which they were taken over. The iron ore rates are advanced a flat 30 cents per gross ton. Lake ore that has paid the advance in a haul to the upper lake docks is not required to pay another advance on the rate from lower lake dock to point of consumption. Limestone goes up a straight two cents per 100 pounds. Coke rates go up by a graduated scale, depending on the size of the present rate, the average being about 30 cents a net ton. Coal goes up on the same principle, and in such a manner that by-product coke will in the main be affected practically as much as beehive coke, the former being generally made at the blast furnace from shipped coal while the latter is produced at the mine and shipped to furnace. The three advances make about $1.11 increased cost per ton of pig iron made, and various incidentals will make the total increase about $1.25 per ton of pig iron. Finished steel will feel a greater effect, as coal and other supplies are also involved, and the increased cost of making a net ton of finished steel will be somewhere in the neighborhood of $1.75.

### Prospective Prices

The freight rate advance has set going the quarterly discussion as to the controlled prices, which late in March were named for the current quarter. In continuing the set prices for the quarter with the slight reductions in scrap and Bessemer and basic pig iron, the War Industries Board was undoubtedly actuated in part by consideration of the fact that the furnaces and mills had had a very hard winter, with especially light production in January and February and exceptionally high costs in consequence. Otherwise there would have been a strong move for a reduction in prices, and in many quarters the idea was that the industry was given three months of grace, in the matter of a reduction in prices, in order to recoup against their supposed light profits in the first quarter of the year. The quarterly reports, however, showed rather fair earnings in January and February, and good earnings in March, while the earnings this quarter are running very large. In the circumstances the War Industries Board would naturally be disposed to seek very considerable reductions. To offset such a demand, the industry has three arguments: (1) The 15 per cent. wage advance that went into effect in April; (2) the increased freight rates; (3) the prospective large increase in the excess profits tax.

The present controlled prices for finished steel are about $40 a net ton above the ten-year average ended with 1913. If the War Industries Board should seek a reduction, therefore, it would be not $1 or $2 a ton, but $5 or $10 a ton. The 15 per cent. wage advance means something like $2 a ton. The freight advance means not over $2 a ton. Thus these two arguments might not be held sufficient to overcome entirely the move for a reduction. As to the excess profits tax increasing, when the proportion of the total steel output which the Government buys and pays for is much greater than the proportion of the total profits it takes as taxes, it is obvious that the Government can make or save more money by reducing prices than by increasing the rate of taxation. If the public were the steel industry's chief customer, it would be enterprising to allow it to make a great deal of money and then take the money as taxes, but when the Government is the chief customer it is more enterprising to reduce the earnings. Thus there is a distinct possibility, though perhaps hardly a balance of probabilities, that there will be lower prices for deliveries after June 30.

### Report Says Very Large Shells May Be Turned Out in Canadian City

Special to CANADIAN MACHINERY.

NEW YORK, June 4.—Machinery manufacturers and dealers are being deluged by a flood of orders and inquiries for equipment of various kinds required by shipyards, ordnance plants, shell makers and other manufacturers of war munitions as a result of the large contracts being placed by the U. S. Government. The Navy and War Departments, also, have put out additional lists of machinery wanted at Government arsenals and other Government plants at Washington, Philadelphia and Norfolk. Railroads and many private manufacturing plants are also inquiring for cranes and other shop equipment. It is estimated that business now pending for machinery of various kinds will call for an expenditure of $100,000,000 in the next sixty days.

### New Shipyards

The Emergency Fleet Corporation has decided upon the construction of two new Government-owned shipyards, one to be located on the Atlantic and the other on the Pacific coast. It is understood that the Bethlehem Steel Corporation will undertake the construction, equipment and operation of the plants, with Government funds. It is stated that each yard will have ten ship ways to be served by its own fabricating, machine and forge shops. Provision is also to be made for the building of additional fabricating shops to serve Government shipyards. One report is that the McClintic Marshall Construction Co., that has shops in various sections of the country, will undertake the building and equipping of the Government plant.

Six shipyards on the Atlantic coast, now active, are also preparing to increase output by extending ways and building new plants and by adding additional equipment to present shops. Four of these yards are already in the market for cranes and fabricating machinery. The New York Shipbuilding Corporation has bought eight cranes and 20 punches as well as other machines. The Newport News Shipbuilding and Drydock Co. is building another boiler shop and has issued a list of machinery required. The Wm. Cramp & Sons Shipbuilding Co. and the Merchant Shipbuilding Corp. have placed orders for cranes with a manufacturer at Kenton, Ohio.

The two new Government shipyards will require nearly 200 overhead electric cranes and 150 to 200 hoists. The fabricating machinery will include 75 to 100 punches and shears as well a large number of other fabricating tools. The Fleet Corporation is also preparing for the extension of present plants and machine shops for the manufacture of marine turbines, boilers and other equipment and various ship parts. The Fed-

Much Equipment

Car builders, steel companies, fabricators, tool manufacturers and copper producers are in the market for cranes of various sizes and most of these plants have war orders of one kind or another. The Ordnance Department has issued a long list of tools to manufacturers in the Ohio Valley including 310 lathes running from 18 to 32 inches, all of which are wanted for shipment to Pittsburg plants. The Grant Motor Corporation is in the market for 20 turret lathes to execute a large order for 6-inch shells for the Government.

Many orders for small lathes, sensitive drills and tappers have been placed in the Central West following Government orders for hand and rifle grenades. Increased activity in the building of agricultural implements and tractors is indicated by the placing of larger orders for shop equipment by such manufacturers. About 40 overhead electric cranes are wanted for gun plants to be built at Neville Island near Pittsburg and at Nicetown, near Philadelphia. Two other large gun plants are to be constructed in the East for the Government, one of which will build guns of 18 inches calibre. The trade is much interested in the placing of large shell orders by the U. S. Government with Canadian manufacturers. It is understood that U. S. interests are about to build a munition plant at Toronto, equipped to manufacture larger shells than have hitherto been made in the Dominion.

### GERMAN TRADE CONDITIONS

Immediate action is demanded by students of German industrial conditions if the decline of German industries is to be avoided. A correspondent of the "Norddeutsche Allgemeine Zeitung" states that immediate action must be taken to develop those which depend on home raw materials, so that immediately after the war Germany may be in possession of commodities with which to pay for the foreign raw materials she will require—textiles, metals, rubber, and foodstuffs. The writer mentions as coming within the purview of his proposal the engineering, small iron, metal, glass, chinaware, brick, timber, potash and chemical industries. Manufacturers in these branches who undertake to push [illegible] should receive preferential treatment at the [illegible]

FROM thirty to forty crucible steel [illegible] in Australia, and steel castings are being regularly produced from fifteen of them. There are seven side-blown converter plants, of which two are owned by the government. One stock converter plant is already in operation and two or three others are being constructed.

## HAVE FIXED PRICES FOR MANGANESE ORE

**War Industries' Board Takes Action—Sliding Scale According to Quality**

WASHINGTON.—Prices for manganese ores produced in this country, as agreed by the American Iron and Steel Institute, have been approved by the War Industries Board. The prices are based on shipments from the west, f.o.b. at South Chicago, and are slightly higher than those that have prevailed in past months.

The prices range from 86 cents per unit of metallic manganese per ton for ore containing, when dried at 212 degrees Fahr., from 25 to 35.99 per cent. of the metallic manganese, to $1.30 per unit for ore containing 54 per cent. or more of metallic manganese. For ore shipped east of South Chicago, fifteen cents per unit of metallic manganese per ton are added to the unit prices.

## GERMAN HAD LIST OF MACHINE SHOPS

**And Had Been Free to Move About the West for Some Time Past**

NEW WESTMINSTER, B.C.—Fritz Bonn, a German, was arrested here and sent to Vancouver. It is said he was in possession of a permit from the Vancouver chief of police to go to Port Mann, and had been there two days. When arrested a list of machine shops was found in his possession. He claims to be a mechanical engineer. Papers found on him show that he had been in Saskatchewan up to May 3, and that he had seven brothers in the German army.

### GOVERNMENT SECURES RAILS FOR RENEWALS

ARRANGEMENTS whereby the need for rails for renewals on the Canadian Government Railways and the Canadian Northern system during the present year will be met have been practically completed by Hon. J. D. Reid, the Minister of Railways and Canals. The purchase of 355 miles of 67-pound rails, which were rolled in the United States under orders placed there by the Russian Purchasing Commission, has been completed and some of the steel is now on its way to Canada.

Negotiations for an additional 150 miles of rails, manufactured for Russia, have also been practically completed, making a total of some 500 miles available for replacement on the lines now owned or controlled by the Canadian Government.

There is also a possibility that 350 miles of 80-pound rails on the Hudson Bay Railway will be lifted for use on lines where traffic is more dense and will be replaced by the lighter rails being obtained from the United States.

From yards and sidings on the National Transcontinental Railway will be obtained about 100 miles of 80-pound rails, and from the St. John Valley Railway in New Brunswick, which is owned by the New Brunswick Government and operated by the Intercolonial Railway, some 120 or 130 miles of 80-pound steel may be secured.

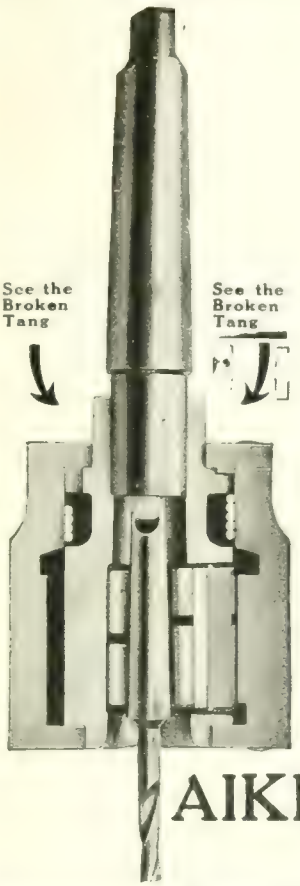
### HOW VESSELS ACT WHEN SINKING

By M. L.

In view of the very large number of vessels that have gone to the bottom of the sea in the last three years, more or less, it is of interest that each particular design of craft has its own peculiar way of sinking. The old single-bottom steamers for example, with a minimum number of bulkheads, almost invariably go down on a more or less even keel, which means that they do not stand on end, as did the Titanic and others since, before they disappear beneath the waters. Modern vessels, however, with numerous subdivisions, perform the feat of diving to Davy Jones' locker either with their bows or sterns high out of the water or by first showing a very heavy list to port or starboard. This is caused by the fact that while a sufficient number of compartments become filled to sink these vessels there are other compartments which remain watertight and prevent the water entering from seeking its level.

### THE ECONOMICAL RECONSTRUCTION OF BELGIUM

In view of the critical situation which will result for Belgium through the disasters caused by the depredations of the enemy—his removing of tools, raw materials, manufactured products, &c. — there has been created, with the co-operation of, and under the control of the Belgian Government, an organization having for its object the economical reconstruction of the country, and styled "Comptoir National Pour la Reprise de L'Activite Economique en Belgique" (Societe Co-operative). This organization has for its aim, by helping industry and trade, and by enabling the Belgian people to purchase tools and the necessary raw materials, not only to reconstruct the economical fabric of the country, but to put an end to the sufferings of the working classes by making it possible for them to start working in the reconstructed shops. In a letter which the newly formed body has issued it is explained that everything interests it, as everything has to be set up again: metallurgy, materials for construction of buildings, leathers, textiles, farming implements, chemical products, wood machines, electrical material, optical instruments, motor cars, vans, wagons, oils and greases of all kinds, refractory materials, &c. In order to enable it to place orders, manufacturers and merchants are requested to send their catalogues and price lists in triplicate to it at 110, Cannon-street, London, E. C. 4., England.



Aikenhead's

Eliminates Waste Motion

# Wahlstrom Chuck

Automatic and instantaneous in action. There's no time lost in waste motion with the Wahlstrom Chuck. It paves the way for increased production and a reduction in costs.

You may use No. 1, 2 and 3 M.T. Shank Tools whether they have a shank tang or not—**the Wahlstrom grips by the entire shank.** Never slips! The cam action is such that the harder the tools take hold in the work, the harder the jaws grip the shank. The grip is smooth, uniform and positive.

**Grips by the entire Shank**

Wahlstroms are made in two styles—one for straight shank tools, the other for M.T. Shank Tools—and they are both automatic—changes are made while the spindle is running.

## AN AMMUNITION DUMP

Every now and then in the official communications from the front comes the word that this or that ammunition dump has been bombed. Very few people have any idea just what an ammunition dump looks like. In the accompanying official Canadian photograph is seen one of these dumps behind the Canadian lines. It gives some idea of the havoc that might result from high explosive bombs dropped in such a location.

### NAVAL ORDNANCE

The development of naval ordnance was for several centuries practically at a standstill. There were no essential differences between the guns used in the Dutch Wars and those with which the ships of the Crimean period were armed. At the opening of the nineteenth century the heaviest naval guns were cast-iron pieces, throwing 32-lb. ball, while 20-pdr. carronades were in almost universal use. One of the few definite stages of progress was reached in 1821, when the first guns were specially designed for horizontal fire with shell, thus superseding the mortar and enabling explosive projectiles to be discharged with a much greater degree of precision. Eight-inch and 10-inch shell guns, made soon afterwards, were tried against the Undaunted, an old frigate, the projectiles being filled with molten iron. The frigate was speedily set on fire by this bombardment. During the Crimean War the heaviest guns carried in the British and French fleets were 68-pounders, most of which were mounted on primitive wooden truck carriages. A few, however, used as chase guns, had special slide carriages, traversing on metal radius plates secured to the deck. Twenty years later such extraordinary progress had been made that guns of 100 tons in weight, firing projectiles of 2,100 pounds, were in use, while Woolwich had prepared plans for a gun to weigh 160 tons, and intended to drive a shot through 36 inches of iron at a range of 1,000 yards. This sudden development in the construction of naval ordnance, following centuries of stagnation, was due, of course, to the advent of the ironclad, against whose iron plates the round shot from the light smooth-bore were useless. To circumvent armor it was necessary to enlist the services of the metallurgist, the chemist, and the mechanical engineer, none of whom had previously had much say in the production of ordnance. The results, as has been said, were amazing, and although the 100-ton muzzle-loader of 1878 may seem a cumbrous, and even primitive, piece beside the 15-inch breech-loader of the present day, it stands out as a marvellous example of mechanical genius when compared with the 68-pounder smooth-bore, the largest gun in existence only twenty years before.

These first 100-ton weapons were manufactured at Elswick for the Italian Government, and were tried at Spezia in 1878, a special (Fassano) powder being used. Results then considered prodigious were obtained. Propelled by a charge of 561 pounds of powder, the 2,500-pound projectile left the muzzle with a velocity of 1,725 feet per second, and an energy of 41,333 foot-tons, and fell into the sea 15,800 yards away. We can best appreciate the merit of this performance by remembering that the muzzle velocity of the Mark VIII. 12-inch gun, mounted in the Majestic class twenty years later, was 2.367 foot-seconds, or only 642 foot seconds more. Another very remarkable example of gun construction was furnished by the Armstrong 10-inch breech-loader, tested at Elswick, in 1879. Using a 300-pound projectile, it attained a muzzle velocity of 2,110 foot-seconds. The first 12-inch B. L. manufactured in England was tried at the Elswick works in 1877. It weighed 39 tons, was 22 calibres in length, and fired a projectile of 700 pounds. The breech mechanism was adapted from the French system, but with a novel type of obturator. With this weapon the initial velocity was 1,615 foot-seconds, and the muzzle energy 12,656 foot-seconds. Considerable attention was also paid at this time to guns of medium calibre, and Woolwich had the distinction of turning out some very successful models. The rifled 6-inch 70-pounder penetrated 8 inches of iron at a quarter of a mile, and with an elevation of 5 degrees the range was 3,795 yards. Elswick, however, continued to lead the way. An Armstrong 8-inch gun of 11½ tons proved capable of piercing 14 inches of iron at 500 yards, which was considered to be the best the 12-inch 35-ton Woolwich gun could do. But, in spite of repeated demonstrations of the fact that light guns could be given a power of penetration almost, if not quite, equal to that of weapons three times their weight, the craze for monster guns continued to prevail for many years, especially in Italy and England. *The Engineer.*

---

FOR etching brasses and bronzes, a few drops of a strong solution of hydrogen peroxide are added to a very dilute solution of chromic acid. The specimen is immersed and kept moving in the solution for a few seconds; it is then removed and washed immediately in running water. The reagent is said to be equally satisfactory for all brasses and bronzes, giving much better results than chromic acid alone.

## THE DEVELOPMENT OF NAVAL GUNNERY

It is a singular circumstance that [illegible] before the days of torpedo and [illegible] the gun was the warship's [illegible] means of offensive, the art [illegible] was neglected in the British Navy, states the *Engineer*. It is true that the superior rapidity with which the British gunners worked their pieces generally gave them the victory over French and Spanish opponents in the wars of the eighteenth and nineteenth ceturies, but at that time little attention was paid to markmanship, because it was not the custom to exchange broadsides until the enemy was practically alongside, and it was harder to miss than to hit. Here and there a captain with unconventional ideas spent time and (his own) money in teaching his men to shoot with accuracy at something beyond point-blank range, but such departures from convention were officially discouraged. The result was seen in the war of 1812, when a series of duels between British and American vessels of approximately equal power ended, for the most part, disastrously for the former. There was no secret about the American successes. They were won invariably by what at that time represented accurate long range gunnery. On two occasions, however, the advantage in this respect rested with the British. The Shannon defeated the Chesapeake, because Captain Broke had schooled his men thoroughly in the science of accurate fire, combined with great rapidity. Captain Hillier, of the Phoebe, similarly defeated the U.S.S. Essex. In his report of this action, Captain Porter, of the Essex, wrote: "The Phoebe, by edging off, was enabled to choose the distance which best suited her long guns, and kept up a tremendous fire which mowed down my brave companions by the dozen. The enemy, from the smoothness of the water and the impossibility of reaching him with our carronades, was enabled to take aim at us as at a target; his shot never missed our hull, and my ship was cut up in a manner never before witnessed." But it was long before the vital importance of cultivating marksmanship was generally recognized in the British service.

Treating of naval gunnery, in his "Fragments of Voyages and Travels" (published in 1833), Captain Basil Hall said: "Officers who have served much afloat in old times tell us that there was a great want of efficiency in that department of naval discipline which relates to the management of the great guns. Many ships, it is true, even during the early period of the last war, were brought into admirable fighting trim by dint of the spontaneous exertions of their commanders. But in these instances the result was generally due to the combined talents, experience, and industry of those particular officers, and owed hardly anything to the merits of [illegible] the fleet. In too many vessels of war, however, the exercise of the great guns was much neglected, or, at most, attended to just so far as the technical rules of the service rendered necessary. And this occurred not infrequently even where there could be traced no want of ability or of zeal on the part of the officers. A plain shore-going person might well ask how it came about that the art of handling the guns should ever be neglected in any man-of-war, when such prodigious sums were expended in equipping her in other respects with every possible requisite to enable her to cope with her enemies. Our ships are greatly improved in strength and every warlike quality, and there is no lack of supplies in any department. Why, then, to the education which is now so general in every other branch of the profession should not that of warlike science and gunnery practice be added?" In making recommendations as to the soundest methods of training, Captain Hall urged that the men be taught to consider it "irksome and disagreeable to make a blustering noise to no purpose," and should be impressed with "the paramount importance of taking such a careful aim, before pulling the trigger, that not a single shot should ever miss." A counsel of perfection, perhaps, but an excellent principle for all gunnery instructors.

It was not until 1830, when Lord Melville established a school of gunnery at Portsmouth, that scientific methods in the handling of naval ordnance obtained official recognition. Even then, however, the innovation was coldly received by the older generation of officers, whose influence outweighed that of the enthusiasts and rendered their attempts to improve naval gunnery more or less abortive. Training was perfunctory, many captains setting more store by paint and polish than straight shooting, and, as the chances of promotion were notoriously more dependent on the smart appearance of one's ship than on her gunnery record, officers had no incentive to over-work themselves in the last-named respect. All through the nineteenth century naval marksmanship was neglected, and it was not until 1898 that the first symptoms of revolution made themselves manifest. In that year the Spanish-American War came to emphasize the lessons of the Yalu with regard to the appalling effect of modern shell fire, and Captain Percy Scott, of H.M.S. Scylla, showed that nothing beyond careful and systematic training was needed to send those deadly projectiles with unfailing accuracy at a distant target.

It is not proposed to describe at length the subsequent stages by which the shooting of the British Navy was brought to an admirable degree of efficiency. In 1903 Captain Scott was appointed to command the gunnery school at Whale Island. Two years later Sir John Fisher laid down new rules of training, mostly directed to the substitution of actual practice for theory, and to putting naval firing on a competitive basis; but the new system did not come fully into operation until Captain Jellicoe was appointed Director of Naval Ordnance in February, 1905. From that time onward the efficiency of every ship was judged from the standpoint of her battle practice record, and it behooved every officer with professional ambitions to take a keen personal interest in the prowess of his ship's gunlayers. The wonderful progress made between 1898 and 1908 was set forth by Sir Trevor Dawson in a lecture he delivered in 1909: "The result of the development in the engineering side of artillery, in the optical accessories, and, in great measure, in the enthusiasm, training, and skill of the gunners, is a marked improvement in the battle practice of the Fleet. The target, which is towed at an unknown speed, course, and range, is only 90 feet long by 30 feet high, less than one-fifth the length of a battleship. One of the latest cruisers put in eighteen hits out of thirty-two rounds from 12-inch guns, and another fifteen hits out of eighteen rounds. Taking all guns in all British ships in commission, the percentage of hits to rounds fired in 1908 was fifty-six, under the new and more severe firing conditions. It may be taken that efficiency in gun practice has more than trebled in ten years."

---

ACCORDING to "The Engineer," an interesting form of sparking plug for motor cars is being developed in the United States, utilizing 'catalytic combustion" to keep the carbon burned off the insulators. The method depends on the maintenance of a high temperature by burning part of the gas-air mixture by catalytic flameless combustion throughout the entire period of the compression stroke, when there is plenty of fresh air in the cylinder. The new plug is provided with a catalytic structure, in addition to the electrodes and inculators, which produces heat by oxxidizing the mixture above mentioned. The catalytic flameless combuston produced by this material is distinct from ordinary flame combustion of the kind that inflames and explodes the whole charge of gas and air. The insulator is kept nearly red hot, and therefore does not receive any deposit of soot, but it does not interfere with the electric spark.

---

IN one of his journals, Camille Flammarion gives the heights at which sounds from the earth are heard from balloons. The shout of a man was heard distinctly at the height of 1,600 ft., the short note of a mole-cricket at 2,500 ft., and the croaking of frogs in a morass at 3,000 ft. At 3,255 ft. a man's voice and the rolling of a cart were distinguished; at 4,550 ft. the roll of a drum and the music of an orchestra; at 5,000 ft. the crowing of a cock, the sound of a church bell, and sometimes the shouting of men and women. Nine hundred feet higher still he heard the report of a musket and the barking of a dog. The noise of a railway train penetrated to a height of 8,200 ft., and the whistle of a locomotive engine to nearly 10,000 ft.

## Special Purpose Shell Tools

The changing over to a new size or type of shell, which so many shell manufacturers find themselves compelled to do, will necessitate many new tools.

Our Special Purpose Shell Tools listed herewith are low in price and efficient in operation. They are designed to do one thing only, but they do that one thing well.

| | |
|---|---|
| Boring Lathes | Shell Cleaning Machines |
| Base Boring Lathes | Undercutting Machines |
| Waving Lathes | Finish Tapping Machines |
| Band Turning Lathes | Inside Profiling Machines |
| Hydraulic Band Presses | Nicking Machines |
| Shell Grinding Machines | Centering Machines |

We can supply any of the above complete, at about half the cost of ordinary tools for the same purpose, or we can furnish you with a complete set of castings ready for you to machine and set up.

Why buy expensive tools when these low-priced tools will do your work equally as well.

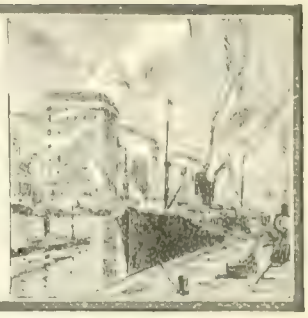
# INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES



## ENGINEERING

**Montreal**—Official notification was received at the headquarters of the Canadian Society of Civil Engineers that the bill amending their charter had received the assent of the Governor-General, thus legalizing the use of the name adopted at the last annual meeting here, as "The Engineering Institute of Canada," under which title the organization will in future be known. Under the new title, it was stated by the secretary, Fraser S. Keith, the association will extend its scope to include the entire engineering profession in Canada, with branches from Halifax to Victoria, for the mechanical, electrical, civil, mining and chemistry, etc., divisions, with sections for each, at the various provincial headquarters, and general headquarters at Montreal.

## MARINE

**Vancouver.**—The shipyard strike in British Columbia, which involved nearly 10,000 men, and which has been on for the last two weeks, is virtually ended, according to announcement by Senator Gideon Robertson, mediator. Eleven crafts of the Metal Trades' Council have agreed to the new scale, it is said, which includes a forty-four instead of a forty-eight-hour week, and fixes a minimum of $3.85 a day for common labor and $6 a day for basic trades. Boiler-makers and electricians are said to be holding out.

**Ottawa.**—"There is under construction in Canada," said Sir Joseph Flavelle, chairman of the Imperial Munitions Board, to-day, "one-quarter of the total merchant tonnage produced in the United Kingdom last year. Eighty per cent. of it will be completed this year. There is one British Columbia shipyard where ten ships of 8,800 tons each would have been built but for the recent serious fire. As it is seven of them will be built. If it had not been for the fire this one yard would have turned out an eighteenth of the total British production."

**St. John's, Nfld.**—The Marine Court of Enquiry which investigated the loss of the steamer Florizel at Horn Head ferry landing near Cape Race on February 24th, made public their findings. They find the mishap was due to faulty navigation by Capt. William Martin, who alone is held blamable, and they suspend his certificate as master for twenty-one months, but allow him a chief mate's certificate for that period because of his good conduct after the wreck. All the other officers and crew are exonerated, and the captain is commended on the manner in which he assumed all the obligation and gave the fullest evidence concerning the tragedy.

**A Pacific Port**—"She acted just like any other vessel," was the way Captain R. E. Connell, commanding the steamer Faith, the largest concrete ship in the world, commented on the vessel's behavior during her trial voyage from another Pacific port to this port, where she arrived. "We had some very rough weather and the Faith certainly stood the test," said Captain Connell. "She responded readily to her helm throughout the voyage." Two research engineers for the Emergency Fleet Corporation and a representative of the United States Lighthouse Service were aboard the Faith as obsedvers on this trial voyage.

## MUNICIPAL

**Endorce the By-law.**—At the last meeting of the Welland Board of Trade the action of the city council in bringing in a bylaw in regard to voting on the proposition to secure the Dillon Crucible Alloys Ltd., was endorsed.

**Hamilton.**—The rebuilding of the Market Hall destroyed by fire last year was endorsed by the Civic Property and License Committee. Plans prepared by F. W. Warren, architect, for the reconstruction of the building were accepted, the estimated cost including installation of a refrigeration system being $105,000. Chairman Cooper and Ald. Radigan and McIntosh wanted the endorsation of the plans postponed indefinitely, but Ald. Tait's resolution that the plan recommended by a special sub-committee, Controller Robson and Ald. Oheir be endorsed, and that construction be started at the earliest possible moment, was carried.

**Edmonton, Alta.**—A. W. Haddow, who has filled the position of acting city engineer since the retirement of A. J. Latornell, has been appointed by the city commissioners to the post of engineer, the full appointing dating from Saturday, May 18. M. Haddow first came to the city in 1909, and previously he was connected with an engineering firm in Northern Ontario. His home is at Simcoe, Ontario. At the outset he did instrument work for the city, and was subsequently made a member of the department. In 1911 he was appointed as assistant city engineer, and in July, 1915, on the retirement of the late A. J. Latornell, he was given the position of acting engineer, which post he has filled up to the present.

## PERSONAL

**Charles A. McCune** has resigned as chief engineer of the Commercial Acetylene Co., to become sales engineer with the Page Steel and Wire Co., 30 Church St., New York, where his efforts will be devoted to sales and service in connection with Armco Welding Rods.

**Milton and Prentiss** have formed a partnership in the business of engineering and machinery and power house brokers, with offices in the Trader's Bank Building, Toronto. A. G. Milton was formerly of the Lincoln Electric Co. and later did business under the name of Archibald G. Milton, his special line being electricity. J. M. Prentiss, his partner in the new business, was for several years secretary of the Chartered Trust & Executors Co., for which concern he had charge of the winding up of the Interurban Electric Co., Ltd. He was also with the Power Plant Equipment Co., organized the Interurban Engineering Co., Ltd., and built and equipped an up-to-date machine shop on Vine Ave., West Toronto. The new firm have the agency of Schaeffer & Budenberg, for recording and pressure gauges and recording thermometers, also for steam jet ash conveyors, and other lines of interest to industrial plants.

## TRADE GOSSIP

**Going to Windsor.**—The Driver-Harris Co., of Harrison, N.J., are going to establish a Canadian business, and Windsor has been selected for the purpose. The company are manufacturers of and dealers in alloys of all sorts. They looked over several Canadian centres before deciding to locate in Windsor.

**One Train Per Day.**—Deliveries of box cars under orders placed by the government are being made at the rate of sixty, or one big train a day. Of locomotives, 185 have been ordered. Work on them has been commenced, and it is expected they will be ready for the moving of traffic during next autumn and winter.

**Women Workers.**—Seven women commenced work in the Grand Trunk shops. This is the first time women have been accepted for this employment. Only the lighter tasks will be given them, but their pay will rank with that of the men. If the women employed at present make good other women will likely be taken on.

**Ten Times As Many**—In last week's CANADIAN MACHINERY reference was made to a dance under the auspices of the C. M. C. Mutual Benefit Society on May 17. In our report it was stated that 300 were in attendance, whereas the figures should have been three thousand. In this case at least it could well be said that "the half was never told."

**Gigantic Merger**—One Union Express Company for the United States was created by agreement between Director-General McAdoo and the Adams, American, Wells-Fargo and Southern Companies, whose transportation business will be merged under a new private corporation, with a capital of more than $30,000,000, to be known, probably, as the Federal Express Company. George C. Taylor, now President of the American, will be the head of the new concern.

**Will Build Factory.**— The "Fenelon Falls Gazette" says: "The Wood Turning Products Co., of Toronto, are to erect a factory in town. Two of their head men were in town last Friday and all final arrangements were made to have a factory located here. The building is to be completed by August 1, and in running order that month. It will be a one-story concrete block building, 120 feet long and 40 feet wide. This company will employ from thirty to forty hands at the start and a few months later will probably employ from 50 to 100."

**Start Nickel Plant**—Coincidentally upon the securing of the necessary raw material, the Port Colborne plant of the International Nickel Company will commence refining operations June 17. This is a month earlier than was at first planned. Necessary additions to the executive staff will be made in the next few days. About 140 workmen are already being employed by the company, and this number will be increased by 200 by the time operations commence. This force will be gradually increased during the next several months until as many as 500 will be included on the pay-roll.

**Getting Suitable Homes**—The John Bertram & Sons Co., of Dundas, are taking steps to overcome the difficulty of the lack of homes and boarding houses for their men. The firm have large contracts and find great difficulty in getting even boarding places for single men. To overcome this, in a measure, the firm have taken over the old basket factory in the west end which is being remodelled and a big dining room will be made in it. Adjoining it the firm will build a large home containing rooms or apartments which they will be able to rent at a reasonable figure to their men.

**Held a Conference**—Refiners of non-ferrous metals were in conference at the

# Manager Wanted $50,000 Salary

A STRONG [illegible] —a man who will create sympathy and respect and support for the greatest factor in the upbuilding of Canada. A man who will curb the few selfish, the grafters, and the offensive combines which exact exorbitant profits, and bring the 95 per cent. decent Canadian manufacturers into disrepute, subjecting them to unfair and confiscatory legislation. A man who will work in unity with the press of the country, with the farmers, trade unions, and various journals, and finally and most important of all—a man who will organize Canadian industry for the greatest possible output of the best quality goods. Such a man can do more than any other to make Canada permanently prosperous. Such a man, says THE FINANCIAL POST of June 1st, should be secured as Manager of the Canadian Manufacturers' Association. You will find the article containing this and other powerfully constructive thoughts on page 1 of THE POST now on sale.

**Know Canadian Affairs**

News of Canadian Securities forms an important feature of THE FINANCIAL POST every week. In addition to the fifteen columns of the June 1st issue devoted to this department the following up-to-the-minute business articles appear:

How the Farmer Looks on High Tariff Policy.
Milling Company Report Not Made on Business Basis.
Banks Prepare for Abnormal Domestic Needs.
Maintenance of Foreign Trade a Necessity
Canadian Merchants Current Loans Millions Higher.
Effect of Victory Loan on Canadian Banks
Facts From Experts as to Frost Score in West.
Outlook for Record Crop Not Impaired
Bank Clearings Show Pre Falling Off
Drain on Bank Staffs Continues
Housing Question Acute in East: Remove Restrictions?
A Bewilder War Outlook and Why (By Lt.-Col. J. B. Maclean.)

These are only a few of the headlines. THE POST is packed full of valuable business information as you will find if you send for a sample copy, or better still a trial subscription using this form:

King Edward Hotel, Toronto, with the Dominion Council of Research, of which Dr. Macallum, of Toronto, is the chairman, with the object of arriving at improved methods through which the maximum amount of metal may be reclaimed. Refineries are operated chiefly in connection with Toronto, Montreal and Hamilton industries. The conference was called by Harry Bayne, Supervisor of Metals and Fibre for the Dominion. Prior to refineries being established in Canada, manufacturers sent their foundry refuse to the United States, where the metals were reclaimed. It was suggested some time ago that a Dominion refinery be established in Canada, but such a step was opposed by Mr. Bayne, who favors the development of the industry among the manufacturers.

**New Incorporations.** — Incorporation has been granted to the following joint stock companies: Lansdowne Park Company, Limited, Brantford, capital $250,000; Statesman Publishing Company, Limited, Toronto, capital $40,000; A. V. Fiola & Company, Limited. Verdun, Que., capital $45.000; Brantford Sales, Limited, Brantford, capital $100 000; Canada Plaster Board Company, Limited, Brantford, capital $100 000; Cluett. Peabody & Company of Canada, Limited, Montreal, capital $1,500,000; Atlee Ranching Company, Limited, Atlee, Alta., capital $100 000; Branham Dredging Company, Limited, Calgary, capital $500.000; United Grain Growers' Securities Company, Limited. Calgary, capital $100.000; Adanac Collieries, Limited, Winnipeg, capital $1,250,000; Ryan's Dry Cleaning Works, Limited. Montreal. capital $25.000; Union Engine Machine Works, Limited Montreal, capital $150.000.

**Western Business Men.**—The organization meeting of the Prairie Provinces branch of the Canadian Manufacturers' Association was held in Winnipeg, when the following officers were elected: Chairman, N. W. Warren; vice-chairman, E. Parnell; executive council, F. W. Adams, J. E. Wildman, J. W. Ackland, M. F. Christie, F. W. Drewry, Wm. Martin, T. R. Deacon, W. S. Fallis, W. R. Ingram, A. B. Stovel; executive committee, W. C. Fraser, D. J. Dyson, L. R. Barrett, F. J. C. Cox, A. Mihalko, Wm. McNealy, R. J. Henderson, Jas. Carruthers, J. Brockest, H. L. Wilson, Wm. Georgeson, H. B. Gordon, W. J. Fulton, L. Crossen, Chas, Watson, C. H. McAuley, L. J. Rumford. G. W. Murray. J. M. Thompson, H. C. Love. C. E. White; chairman transportation: W. R. Ingram; tariff committee: T. R. Deacon; legislative committee: E. Parnell; insurance committee, W. S. Fallis, membership committee, J. M. Thompson. The question of the West having to depend on Western coal this winter was discussed at length. The matter of co-operating with farmers' organizations for the purpose of getting in the harvest was also taken up.

**An Interesting Case.**—Judge Denton, in the County Court, reserved his judgment in a case of interest to contractors. In May, 1917, W. B. Graham submitted to the Board of Education a tender for $14,200 for carpenter work at Orde Street School. Next day he discovered that he had left out $3,500 for labor, and asked to be allowed to amend his tender. The Board refused to grant this request, and when Graham would not carry out the contract which was awarded to him, declined to return his deposit of $710. The contract was finally awarded to Crocker and Le Drew, whose tender amounted to $18,000. Graham claimed for the return of his deposit and a declaration that no contract existed between him and the Board of Education. The Board argued that a contract once accepted and sealed was irrevocable, and counter-claimed for $3,250, the difference between the tenders. Crocker, in the witness box, stated that in his contract he allowed $3,250 for labor, and when the question arose as to whether the Board's officials did not take special notice of the big difference in the amounts of the tenders, Superintendent of Buildings Bishop showed that the Board was accustomed to such variation, and recalled an instance where the lowest carpentry contract accepted and fulfilled was $5,477 and the next lowest $8,900, a difference of $3,450.

## CONTRACTS

**Ottawa.**—The Dominion Government, to relieve the scarcity of office accommodation for its purposes in Ottawa is to erect a nine-story office building covering a space of 200 by 150 feet. The contract was awarded to-day to Bate McMahon and Co., of Ottawa, whose tender of $1.969,000 was the lowest of several received from big contracting firms.

## BOOK REVIEWS

**Condit Electrical Protective Devices** is the title of a unit type of bulletin issued by the Condit Electrical Mfg. Co., Boston. As the title suggests the bulletin is devoted to the various oil switches and protective devices manufactured by the firm and includes current transformers, relays and other auxiliary apparatus. One section is devoted to unit panels for the controlling of induction and synchronous motors.

### SCIENTIFIC PRECISION

Sir Richard Glazebrook says that the work of the Engineering Standards Committee has been of untold advantage to the country. At every step of that work the committee have kept in close touch with scientific principles, and researches of the most varied character have been carried out, and are being carried out now, with a view to determine what standards to set up, what tests to prescribe.

Nor is it enough to say that much of this has been done and need not be carried further; the principles on which ammeters and voltmeters are made have been thoroughly investigated, the optical laws with which telescopes and lenses

must comply are well known; lay down your tests and specifications and train observers, analysts and testers to enforce them, and you have done all.

Stagnation and death, not life and progress, lie that way. It is not our object merely to apply with rigid fairness the laws laid down and to be pleased rather than otherwise, like the mythical examiner, when we plough every sample. The standards set must be reasonable, but they must tend to raise the quality of the product tested. Recurring defects must be watched and investigated, and the tests modified to prevent them: you must gain the confidence of the manufacturer and lead him to realize you are out to help him, and that you really know something, probably more than he does, of the strength and weakness of his goods. Nearly all Englishmen are anxious to maintain the reputation of their country, and welcome fair tests which show up bad work and make for its improvement. Our statistics show the improvement that is produced by tests properly carried out. —*Engineering.*

THERE is now being developed under the name of the Hunnewell hull a new type of ship's hull, consisting of a steel or wood middle body and concrete ends, especially designed for the rapid and economical building of sea-going cargo vessels, says "Marine Engineering." This new style of hull, for which patents have been applied, is the invention of Constructor F. A. Hunnewell, U.S. Coast Guard, and is receiving attention from both naval constructors and private ship owners and designers.

IN an article in "Motorship" on submarine activity, a writer says that if large numbers of camouflaged, mastless and funnelless, motor-driven freight and tank ships were engaged in the transatlantic service, Germany would need submarines stationed at least every ten miles north and south. In other words, she would need a maintained fleet of fifty U-boats effectively to operate a lane of 500 miles wide, instead of about twelve that she now needs. The article states that the Diesel-driven vessel will play a great part in this war.

Scandinavia Belting
Is a Good Belt for Dusty Places

In cement plants and brick plants where there is lots of dust this belt is producing results that are very satisfactory for the mill operators.

You know how wearing grit is on a belt, and you want a belt that will not come apart when only partly worn through.

"Scandinavia" is this kind of a belt—there are no plies to come apart, it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends, the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one, please. It will be a pleasure to us both.

Federal Engineering Co., Limited

# Modern Belting Practice: Installation, Use and Care of Belts

## Choice of Belting Material—Arrangement of Drives—Proper Method of Lacing—Strength and Thickness Requirements—Useful Formulae

By M. H. Potter

IF possible to avoid it, connected shafts should never be placed one directly over the other, as in such case the belt must be kept very tight to do its work. For this purpose belts should be carefully selected of well-stretched leather.

### Arrangement Features

It is desirable that the angle of the belt with the floor should not exceed 45 degrees. It is also desirable to locate the shafting and machinery so that belts should run off from each shaft in opposite directions, as this arrangement will relieve the bearings from friction that would result when the belts all pull one way on the shaft.

In arranging the belts leading from the main line of shafting to the counters, those pulling in an opposite direction should be placed as near each other as practicable, while those pulling in the same direction should be separated. This can often be accomplished by changing the relative positions of the pulleys on the counters. By this procedure much of the friction on the journals may be avoided.

If possible machinery should be so placed that the direction of the belt motion shall be from the top of the driving to the top of the driven pulley, when the sag will increase the arc of contact.

The pulley should be a little wider than the belt required for the work.

The motion of the driving should run with and not against the laps of the belts. Tightening of guide pulleys should be applied to the slack side of belts and near the smaller pulley.

### Care of Belts

Belts made of coarse, loose-fibred leather will do better service in dry and warm places, but if damp or moist conditions exist then the very finest and firmest leather should be used.

Leather belts should be well protected against water, loose steam, and all other moisture, with which they should not come in contact. But where such conditions prevail fairly good results are obtained by using a special dressing prepared for the purpose of water-proofing leather, though a positive water-proofing material has not been discovered.

### Rubber Belting

The advantages claimed for rubber belting are perfect uniformity in width and thickness. It will endure a great degree of heat and cold without injury; it is also adapted for use in damp or wet places, or where exposed to the action of steam, it has great tensile strength, and when adjusted for service it has the most perfect hold on the pulleys, hence is less liable to slip than leather.

Rubber belting manufacturers claim that rubber belts will be improved, and their durability increased, by putting on with a painter's brush, and letting it dry, a composition made of equal parts of red lead, black lead, French yellow and litharge, mixed with boiled linseed-oil and japan enough to make it dry quickly. The effect of this will be to produce a finely polished surface. The best conditions are large pulleys and high speeds, low tension and reduced width of belt; 4,000 feet per minute, is not an excessive speed on proper sized pulleys.

### Sag of Belts

In the location of shafts that are to be connected with each other by belts, care should be taken to secure a proper distance one from the other. The distance should be such as to allow of a gentle sag to the belt when in motion.

A general rule may be stated thus: Where narrow belts are to be run over

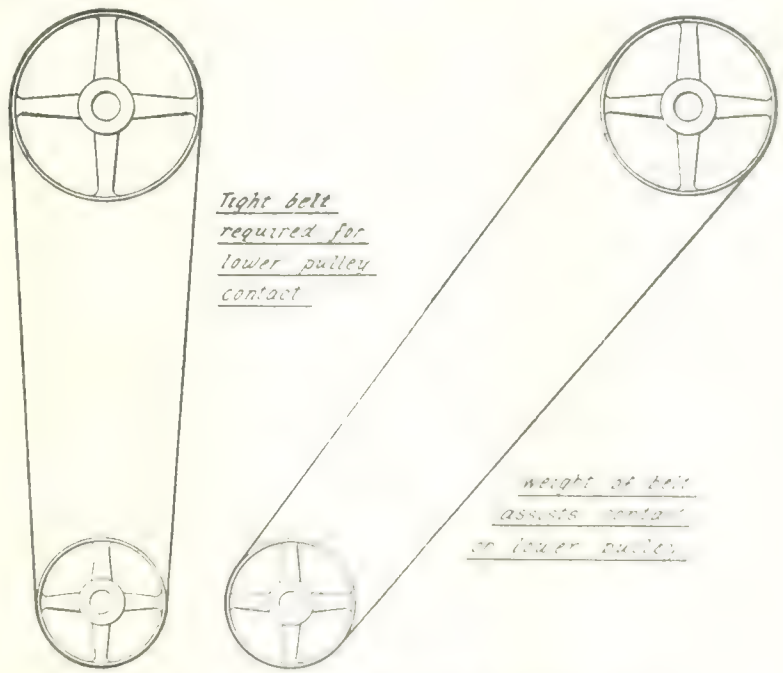

FIG. VERTICAL AND INCLINED BELT DRIVES

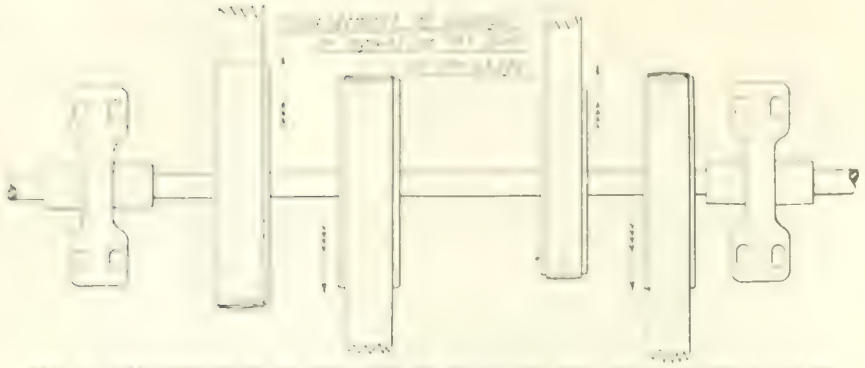

FIG. 2. ARRANGEMENT OF PULLEYS TO EQUALIZE THE PULL ON THE SHAFT

of each pulley at the extremity of the horizontal diameter where the belt will leave the pulley, and then set that point on the driven pulley plumb over the corresponding point on the driver. This will cause the belt to run squarely on to each pulley, and it will leave at an angle greater or less, according to the pulleys and their distance from each other. In quarter-twist belts, in order that the belt may remain on the pulleys, the central plane on each pulley must pass through the point of delivery of the other pulley. This arrangement does not permit of reversed motion.

### Tight Belts

To tight belts can be traced a large percentage of broken pulleys, hot boxes, etc.; the enormous and useless pressure thus put upon pulleys must in time break them, causing heating and consequent destruction of the bearings.

Clamps with powerful screws are often used to put on belts with extreme tightness, and with most injurious strain upon the leather. They should be very judiciously used for horizontal belts, which should be allowed sufficient slackness to move with a loose undulating vibration on the returning side, as a test that they have no more strain imposed than is necessary simply to transmit the power.

### Setting a Belt on Quarter-Twist

A belt must run squarely on to the pulley. To connect with a belt two horizontal shafts at right angles with each other, requires a quarter-turn. First, ascertain the central point on the face

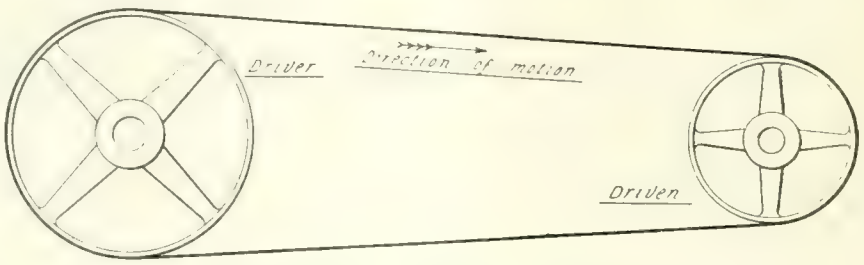

FIG. 3. PREFERABLE DIRECTION OF BELT MOTION.

### Lacing of Belts

In punching a belt for lacing, use an oval punch, the longer diameter of the punch being parallel with the sides of the belt. Punch two rows of holes in each end, placed zigzag. In a 3-inch belt there should be four holes in each end—two in each row. In a six-inch belt, seven holes, four in the row nearest the end. A 10-inch belt should have nine holes. The edge of the holes should not come nearer than ¾ of an inch from the sides, nor ⅞ of an inch from the ends of the belt. The second row should be at least 1¾ inches from the end. On wide belts these distances should be even a little greater.

Begin to lace in the centre of the belt and take care to keep the ends exactly in line, and to lace both sides with equal tightness. The lacing should not be crossed on the side of the belt that runs next the pulley. In taking up belts, observe the same rules as putting on new ones.

### Strength of Belting

The ultimate tensile strength of belting does not generally enter as a factor in calculations of power transmission. The strength of the solid leather in belts is from 2,000 to 5,000 pounds per square inch; at the lacings, even if well put together, only about 1,000 to 1,500. If riveted, the joint should have half the strength of the solid belt. The working strain on the driving side is generally taken at not over one-third of the strength of the lacing, or from one-eighth to one-sixteenth of the strength of the solid belt.

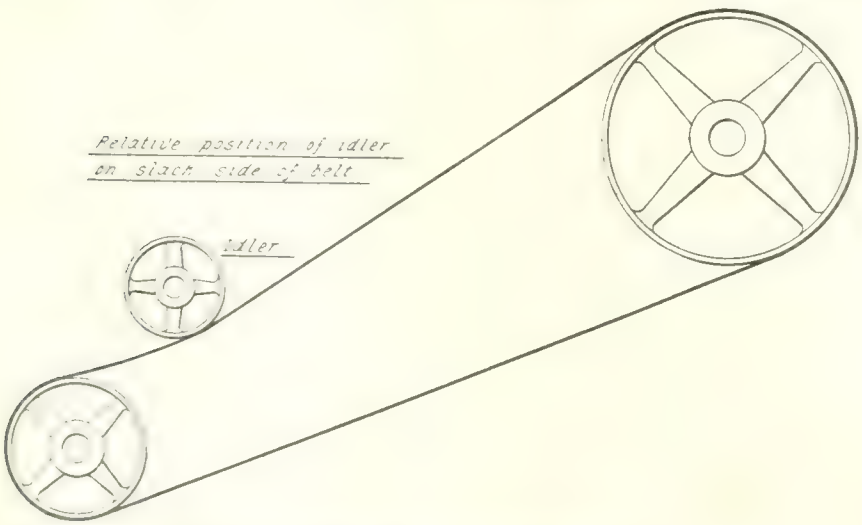

FIG. 4. INCLINED BELT DRIVE WITH IDLER.

### In General

The average double belt when running night and day in a machine shop will cause at least 26 interruptions to manufacture during its life, or 5 interruptions per year. The oak-tanned and fulled belts show themselves to be superior in all respects except in coefficient of friction to either the oak-tanned, not fulled, the semi-raw hide, or raw-hide with tanned face.

Belts of any width can be successfully shifted backward or forward on tight or loose pulleys. Belts running between 5,000 and 6,000 feet per minute and driving 300 horse-power are being daily shifted on tight and loose pulleys, to throw lines of shafting in and out of use.

The best speed for maximum economy should be from 4,000 to 4,500 feet per minute. Belts are more durable and work more satisfactorily made narrow and thick, rather than wide and thin. It is safe and advisable to use a double belt on a pulley 12 inches in diameter or larger, a triple belt on a pulley 20 inches in diameter or larger, a quadruple belt on a pulley 30 inches in diameter or larger. Double leather belts, when treated with great care and run night and day at moderate

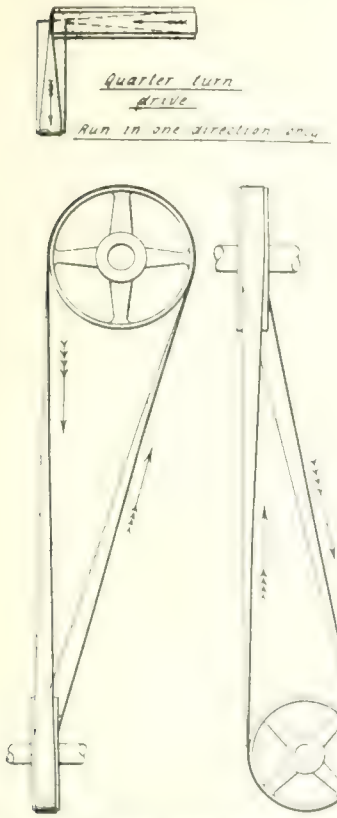

FIG. 5. QUARTER TURN DRIVE RUN IN ONE DIRECTION ONLY.

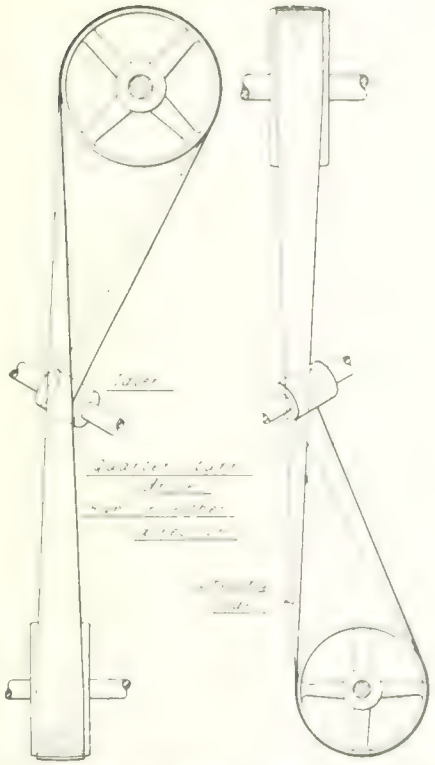

FIG. 6. QUARTER TURN DRIVE REVERSIBLE

speed, should last 7 to 18 years, depending upon the total load. In figuring the total expense of belting, and the manufacturing cost chargeable to this account, by far the largest item is the time lost on the machines while belts are being relaced and repaired.

By increasing the thickness of a belt, the power transmitted ought to increase in proportion; and for double belts we should have half the width required for a single belt under the same conditions. With large pulleys and moderate velocities of belt it is probable that this holds good. With small pulleys, however, when a double belt is used, there is not such perfect contact between the pulley-face and the belt, due to the rigidity of the latter, and more work is necessary to bend the belt-fibres than when a thinner and more pliable belt is used.

The centrifugal force tending to throw the belt from the pulley also increases with the thickness, and for these reasons the width of a double belt required to transmit a given horse-power when used with small pulleys is generally assumed not less than 7 10ths the width of a single belt to transmit the same power.

The most intimate contact of a belt with a pulley comes, first, in the smoothness of a pulley face, including freedom from ridges and hollows left by turning tools; second, in the smoothness of the surface and evenness in the texture or body of a belt; third, in having the crown of the driving and receiving pulleys exactly alike—as nearly so as is practical in a commercial sense; fourth, in having the crown of pulleys not over ⅛-inch for a 24-inch face, that is, that the pulley is not to be over ¼ inch larger in diameter in its centre; fifth, in having the crown other than two planes meeting at the centre; sixth, the use of any material on or in a belt, in addition to those necessarily used in the currying process, to keep them pliable or increase their tractive quality, should wholly depend upon the exigencies arising in the use of belts; non-use is safer than over-use; seventh, with reference to the lacing of belts, it is good practice to cut the ends to a convex shape by using a former, so that there may be a nearly uniform stress on the lacing through the centre as compared with the edges.

### To Find Length of Belt

When the length cannot be measured directly by a tape line, the following approximate rule may be used: Add the diameter of the two pulleys together, divide the sum by two, and multiply the quotient by 3¼, and add the product to twice the distance between centres of the shafts.

To find the length of belt when closely rolled: The sum of the diameter of the roll, and the eye in inches × the number of turns made by the belt and by .130 = length of the belt in feet.

To find the approximate weight of belts: Multiply the length of belt, in feet, by the width in inches, and divide the product by 13 for single and 8 for double belts.

### Driving and Driven Pulleys

The driving pulley is called the driver, D, and the driven pulley the driven, d. If the number of teeth in gears is used instead of diameter, in these calculations, number of teeth must be substituted wherever diameter occurs. R = revolutions per minute of driver, r = revolutions per minute of driven.

$$D : d :: r : R$$
$$d : D :: R : r$$
$$R : r :: d : D$$
$$r : R :: D : d$$

To find the angle of the arc of contact of a belt: Divide the difference between the radii of the two pulleys in inches by the distance between their centres, also in inches, and in a table of natural sines find the angle most nearly corresponding with the quotient. Multiply this angle by 2, and add the product to 180° for the angle of contact with the larger pulley or subtract it from the smaller pulley.

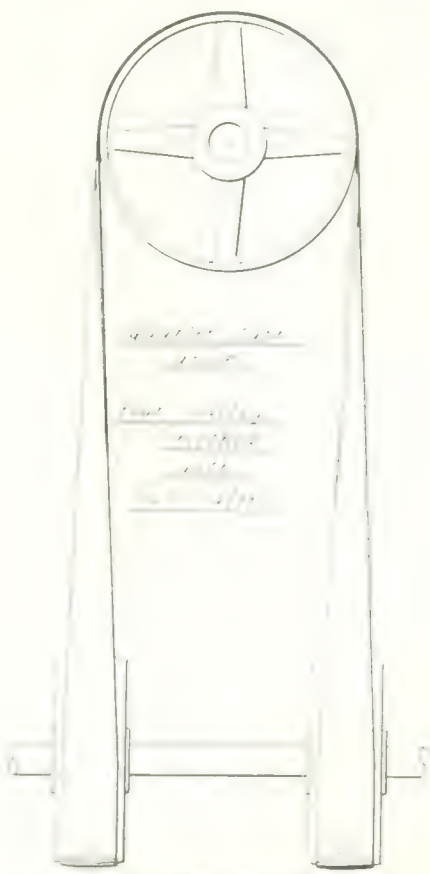
For example, let

R = radius of larger pulley.
r = radius of smaller.
L = distance between centres of pulleys.
a = angle whose sine is (R-r) ÷ L.
Arc of contact with smaller pulley = 180°-2a.
Arc of contact with larger pulley = 180°+2a.

To find the length of belt in contact with the pulley: For a larger pulley, multiply the angle a, found as above, by .0349, to the product add 3.1416, and multiply the sum by the radius of the pulley. Or length of belt in contact with the pulley =

$$\text{radius} \times (3.1416 + .0349a)$$

For the smaller pulleys length = radius × [3.1416 − (.0349a)].



QUARTER TURN DRIVE

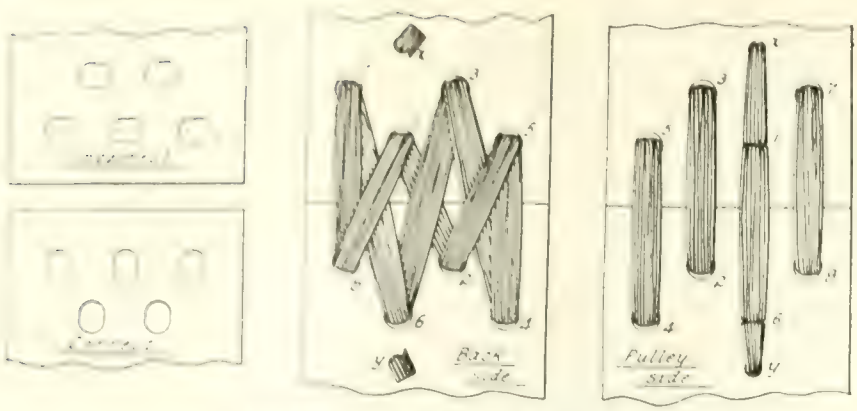


FIG. 8—METHOD OF LACING BELTS.

The above rules refer to open belts. For crossed belts the formula is:

$$\text{Length of belt} = 3.1416R\left(1+\frac{S}{90}\right)+3.1416r\left(1+\frac{S}{90}\right)+2L\cos S=(R+r)\times(3.1416+.0349S)+2L\cos S.$$

in which S = angle whose sine is $\frac{(R+r)}{L}$; $L\cos S=\sqrt{L^2-(R+r)^2}$; $L=\frac{(R+r)}{\sin S}$.

## OIL FLOTATION PROCESS INCREASES PRODUCTION OF METAL

THE good results of the policy of the Government in assisting leaders in the extractive and manufacturing industries to solve the problems which are too big for any individual or company, are being made manifest daily. The Cobalt mining camp has been a great producer, and in this time of war it is more than ever essential that this production be maintained and increased. One of the greatest factors in increased production has been the introduction of the oil flotation process of ore reduction, which process has in some ores resulted in the production of 20 per cent. more metal than could be secured by any other process. This process has, up to within the last few months, depended upon an oil which can be produced in comparatively small quantities only. It is known as "pine oil," and is produced by the redistillation of turpentine in the "hard" pine regions of the southern United States.

### Many Plants Erected

The great success of the oil flotation process caused the erection of many plants throughout the United States, with the result that Canadian reduction plants always had a most precarious supply and were in danger of being cut off altogether at any moment. The price was high because of the scarcity of the article, but it was not price but actual shortage which worried Canadian mining operators. In this situation some of the Cobalt mine owners began experimenting, but while they secured some results, they realized that mining and reduction was the business of the miner, not experimenting. They then applied to the Minister of the Interior to have the Forestry Branch take up the problem of ascertaining whether pine oil could be made from Canadian pine trees, and also whether a cheaper substitute could be discovered. The Forest Products Laboratories, which forms part of the Forestry Branch, took up the work and after three-quarters of a year of experimenting produced both a Canadian pine oil (extracted from red pine stumps) and a much cheaper substitute.

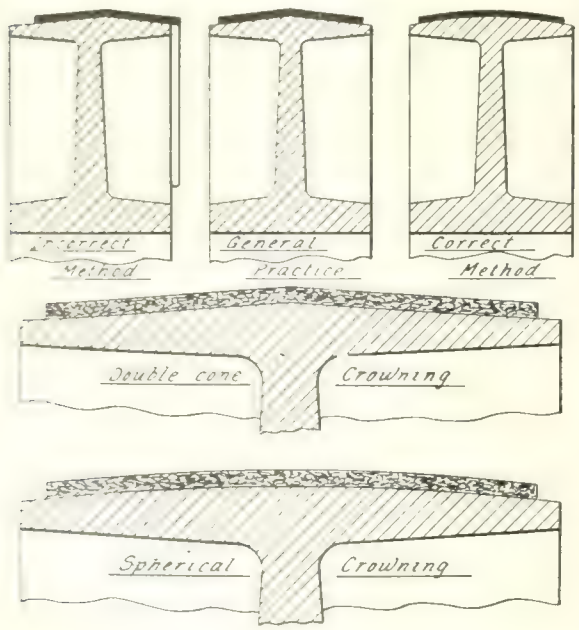

FIG. 10—VARIOUS METHODS OF CROWNING PULLEYS.

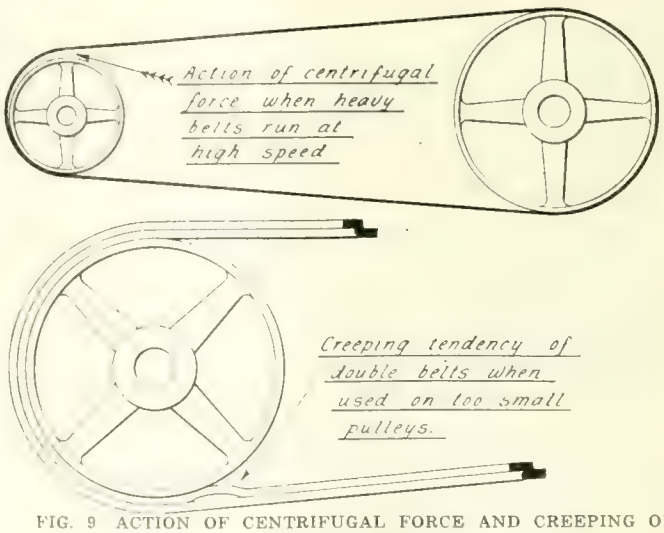
As each oil was extracted in the Forest Products Laboratories it was immediately tested by the Mines Branch in the ore dressing station at Ottawa to prove its efficiency with the different samples of Canadian ore. There was thus no time lost in ascertaining which blends of oils were most useful with particular ores; and this testing was another example of the ability and readiness of the different Government departments to do good "team work" in solving a problem for the good of the producers of the country.

### Shifted to the Substitute

The interest of miners naturally shifted from expensive pine oil to the substitute, which up to the present has been a waste product of the wood distillation industry. This is one of the creosote oils which come off in the distillation of wood alcohol, etc. It is being produced at the rate of about twelve hundred gallons per day in Canada, so that the owners of mineral reduction plants point out there is plenty for the expansion of our own mining industry and also some for export.

The discovery has naturally been received with great satisfaction by Canadian mining men, and it is no less satisfactory to the wood distillation industry. Thus by the Government's aid in handling the scientific part and setting its experts to solve a general problem two important industries have been



Action of centrifugal force when heavy belts run at high speed
Creeping tendency of double belts when used on too small pulleys.

FIG. 9 ACTION OF CENTRIFUGAL FORCE AND CREEPING OF DOUBLE BELTS.

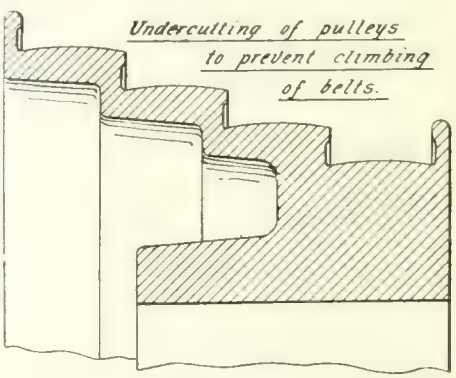


FIG. 11 UNDERCUTTING OF PULLEYS TO PREVENT CLIMBING.

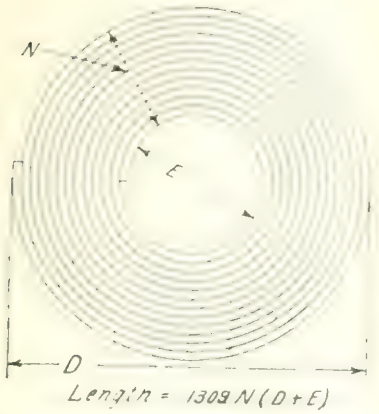

FIG. 1. TO DETERMINE THE LENGTH OF A ROLLED BELT

greatly aided and their managers set free to devote themselves to the particular problems of production; and through this the whole industry and commerce of Canada has been benefited.

## PRINTED COPIES OF PATENT SPECIFICATIONS

**Hanbury A. Budden, Montreal Patent Counsel, Submits Statement to the Minister of Agriculture**

Sir Robert Hadfield, president of the Society of British Gas Industries and head of the great firm of Hadfield Limited, Sheffield, in a recent address on Patent Law Reform made the following statement:

"As an example of the antedeluvian policy of our Empire on this question an Englishman in this country cannot get a copy of a Canadian patent without sending to Canada, and even then he gets only a typewritten copy, as patent specifications are not printed there."

This condition of affairs in the Patent Office, Ottawa, is one that demands immediate attention.

The Canadian Patent Office have issued over 180,000 patents and Canada ranks seventh among the countries of the world issuing patents for inventions.

A copy of a British patent costs eight pence, while the U. S. Patent Office sell copies at 5 cents apiece.

A copy of a Canadian patent costs on an average over two dollars and can only be obtained after considerable de-

In the U. S. Commissioner of Patents' report to Congress for the year ending December 31st, 1917, the following figures are given relating to this subject:

Printed copies of specifications and drawings of patents to the number of 2,511,082 were sold at five cents each, bringing to this office on this account $125,554.10. For 1,277,184 copies sold to libraries the office received $1,612.50. The total received from the sale of copies of patents was $127,166.50.

Copies to the number of 1,097,550 were shipped to foreign Governments and 142,640 copies were drawn for office use. The total number of printed copies of patents distributed during the year was 5,354,126.

These figures show that there is a great demand for printed copies.

The public is interested in the publication of patents because it has the right to know the terms of the grant of a monopoly in order to avoid infringement while the monopoly exists, and it has also the right to know what has become public property when that monopoly ceases.

The patentee is interested in the publication of patents as he would readily purchase a number of copies of his patent, to assist him in exploiting his invention.

The Patent Office is urgently in need of printed copies not only to supply the examiners' files, but also to fulfill an agreement with the U. S. Patent Office to exchange copies.

In Great Britain and the United States the libraries in all the great centres contain copies of patents for reference. In Canada it is necessary to go to Ottawa to make a search and even then the cumbrous typewritten copies, which are not properly classified, make a search difficult and tedious.

The Canadian Patent Act as it now stands provides for the printing of specifications and drawings in Section 63, subject to the approval of the Governor in Council.

Undoubtedly it will take a long time to print the 180,000 patents which have been already issued, but that is a matter for special consideration.

There is no doubt, however, that the system of printing specifications and drawings should be adopted at once and thus prevent the increase of arrears.

Canada has reached such a stage in her development that she should endeavor to be among the progressive nations particularly in matters that concern her intercourse with other nations. The present time of rapid industrial and technical advance demands a change from old methods which may have been suitable for a young country. The contrast between our methods and those of our neighbor of the south is very striking and great efforts should be made to reorganize our primitive system and bring it up to date.

## PRESERVING AND DRYING TIMBER ELECTRICALLY

WOOD, as soon as it ceases to exist as a growing tree, quickly becomes a prey to the germs enclosed within it. Therefore, as it constitutes one of the most necessary materials of industry, it is readily realized that it is advantageous to utilize the wood as quickly as possible after the tree from which it is taken has been felled, and to preserve it in perfect condition. The problem is one that has so far only been partially solved for the subject is extremely complex and comprises, apart from the technical difficulties, various very important economical and industrial requirements.

### Process Requirements

It is, primarily, necessary that the processes employed for the rapid drying of wood shall not be costly or difficult of execution. They should be applicable not only in suitable works but on the land, i.e., in woods and forests themselves. It is necessary also, that the results obtained shall be uniform throughout the whole mass of the wood, and that the constituents of the same shall be absolutely and permanently unalterable in character.

All these conditions are completely realized in the electric process recently patented and put into practice by M. Albert Nodon. So far back as 1896, M. Nodon devised a process for the "senilization" or aging of wood by electricity, but it required a somewhat complicated and costly equipment of vats, screw jacks, cranes, heating apparatus, etc., which rendered the cost of working too high. Not only so, but the method gave somewhat irregular results. M. Nodon, however, continued his experiments and at last succeeded in modifying the process to such an extent as to render it both practicable and economical.

Exhaustive tests carried out in the application of a current of electricity to the drying of wood show it to give rise to a triple action—chemical, physical, and aseptical. As a matter of fact the results achieved comprise (1) a total and rapid oxidation of the resiniferous materials contained in the sap, (2) a molcular transformation of the cellulose and the various derivatives which modify the mechanical properties of the timber, and (3) a complete and definite suppression of all the destructive germs contained in the wood.

### Details of Process

The very simple arangement for drying and preserving wood devised by Mr. Nodon consists of the employment of what is known as "carpet" electrodes, which may readily be transported for use at any place when previously rolled on a wooden core. The carpets are made of a flexible metallic "cloth," of galvanized iron, fixed between two large sheets of jute, which form absorbing mattresses. The carpets, after being extended over the wood to be treated, are saturated with water, thus rendering them good conductors of electricity.

If the process is to be carried out in a factory, a simple floor is made of joists and floor boards, on which the first wet carpet electrode is laid. On this a layer of green wood, that has been cut to the desired shape and size, in the form of baulks, sleepers, beams, planks, etc., is placed. This first layer of wood is covered with another carpet electrode, then another row of wood, and another electrode, and so on, until the pile has reached the desired height, say 1m. or 1½m. The metallic portions of the carpets are connected to conductors at the sides, the poles of the successive carpets being alternated in order that the current may pass through each layer of timber. In this way, the internal resistance of the pile is reduced to a minimum. The current passes through all the baulks in the direction of their thickness, owing to the conductivity of the electrodes and the sap in the green wood. The resistivity varies according to the thickness, the amount of essential oil, the degree of humidity and the time of felling, and ranges between 6 and 20 ohms per cubic metre, remain-

[illegible] the whole period of the treatment.

To cause a current of an intensity of from 5 to 6 amperes to pass through a cubic metre of wood in the form of baulks, the E. M. F. varies, according to circumstances, from 30 to 100 volts. An alternating current at 110 volts and 40 to 50 periods may be utilized, but it is preferable to adopt a lower frequency, say 15 to 20 periods per second, and a lower E. M. F. The latter is regulated to give the desired current by means of induction regulators or transformers. Continuous current at 110 volts may also be employed.

### Regulation

The results are the same as with alternating current, but the electrolysis that takes place quickly affects the carpet electrodes, necessitating a frequent reversal of the directions of the current flow through the pile of timber.

Regulation of the continuous current can only be effected by means of ohmic resistances, the efficiency of which is lower than that of the induction regulators. For these reasons, it is preferable to employ alternating current.

The process can also be carried out with great advantage in woods and forests when timber is in full sap, during the summer time, for it is in that period the wood possesses its maximum of vitality and industrial qualities. It is also the best season of the year for outdoor work. The trees can be advantageously cut up by portable electric saws worked by current from a portable steam-operated generating plant, the boiler of which can be fired with the waste timber resulting from the felling and the sawing. The piles of wood, with their carpet electrodes, are arranged on a small area of cleared land near where the trees are being felled, while the treated wood can be stored in any position where it is exposed to strong winds.

### Capacity

The time necessary for drying wood by the Nodon process varies from one to two full days, according to the nature of the timber and the results it is desired to secure. It may be noted that when the process is carried on too rapidly cracks or splits may be caused in the wood. The current should therefore be regulated to from 4 to 5 amps. per cubic metre for timber intended for carpentry and cabinetmaking work. For other uses such as railway ties, the strength of the current may be increased to 10 amps. per cubic metre. The sum total of the current which should be passed through a cubic metre of wood is 150 amps. hours, that is to say, the time varies from one to two days according to whether a current of 10 or 5 amps. is employed. The operation can be suspended at the end of the regular working day, and restarted the next morning without inconvenience or drawback. All that is necessary in such a case is to keep the carpet electrodes damp in order that the resistivity of the pile may not increase. If the timber is not stripped of its bark, an E. M. F. of from 80 to 100 volts is necessary; if, however, it is stripped, and in full sap, a pressure of 40 volts is sufficient.

### Effect on Wood

Wood dried by the Nodon process, or "nodonized" as it is rapidly becoming known in France, is deprived of starch, but retains the resiniferous materials throughout the whole mass, the cellules of the sap-wood have also a characteristically regular appearance which enables by means of reactions and micrographic examinations the wood that has been treated electrically to be distinguished from that which has not been submitted to the process. The cost of installation and working is restricted to the purchase of the carpet electrodes and the energy consumed. The electrodes are easily made, and their cost works out at an average of about 4 francs per square metre. The cost of electrodes per cubic metre of treated wood is approximately 40 francs, while they have an average life of twelve months, if the necessary care is taken to reduce the wear to a minimum. The depreciation, on this head, works out at approximately 2c per day per cubic metre.

### Industrial Uses

As for the industrial applications of the process, these are almost as numerous as those of wood itself. For carpentry and joinery work, perfectly dry timber that will not become moist or rot is necessary. Especially, also, is this the case as regards materials for the construction of boats, vessels of small tonnage, bridges, gangways, jetties, etc. Military authorities and public works departments also find it advantageous to employ perfectly dried timber.

Some official tests have recently been made on the application of the French Government, the results of which and the reports on the same have been entirely favorable to the process, and some further specific tests for Government Departments are at present in progress. The Nodon process can also be advantageously adopted for the rapid and complete desiccation of certain Colonial species, such as pseudo-mahogany, which comes from the African coast in the form of large bark-covered logs, and which, on arrival in France, are still full of sap, rendering their treatment in stoves unsatisfactory. Such material can be treated by the Nodon method not only efficiently but also at a much lower cost.

As regards wood paving blocks, the use of which is steadily increasing in large towns, it has been a general experience that, owing to their relatively short life, they have frequently to be renewed, the processes hitherto employed having failed to give the desired results. An official report, issued in January last by the municipal authorities of Bordeaux, shows, however, that electrically-treated wood gives full satisfaction as regards durability. Indeed, the official report, a copy of which lies before us, stated that one of the busiest roads in Bordeaux was partially paved in 1906 with wood blocks treated by the Nodon process, and that, although eight years have since elapsed, the part of the road so paved is still as level as on the day it was laid, while the other portions paved with blocks treated in the ordinary way have had to be relaid.

Finally, we may draw attention, among the other important applications, that of railway ties and pitwood, in addition to telegraph and telephone poles, and electricity and transmission masts. It will thus be seen, from the numerous directions in which it can be applied, that the Nodon process promises to effect a radical change in the methods of drying and preserving wood. It may be added in conclusion that the process is in the hands of Societe A. Beaumartin & Co., of 33, Rue St. Genes, Bordeaux.

## TWO KINDS OF SAFETY

By D. A. Middleton

Down in Schenectady almost every worker is either a G. E. or an Alco man. In the rush of war orders a couple of years ago one of these companies bought an unused factory building, and in a remarkably short space of time had machinery installed and an army of men at work. This gang had been at work about two weeks and in that time had turned out parts enough to kill off thousands of fearless men over there, when all of a sudden came the order to stop work.

It seems that in the rush of getting started such trifles as guards for belts and gears and other moving things had been entirely overlooked and might have gone on so had not an indemnity insurance man happened along just then on his semi-annual inspection trip. Insurance laws are very strict in New York State, and everything (almost) is guarded. The inspector's say-so was proof against persuasion so right then the plant took a four day rest while guards were fitted to the machines to make them safe for the industrial army —guarding against the possible loss of a finger—even the inspector was forced to smile when the superintendent pointed out in the consistency of the move and the grim purpose for which the product was intended.

## PRIZE OFFERED FOR METHOD OF DETERMINING HARDNESS

The Institution of Mechanical Engineers holds a sum of £200, presented last year by Sir Robert Hadfield, which, with any income therefrom, may be awarded at the discretion of the Council of the Institution as a prize, or as prizes, for the description of a new and accurate method of determining the hardness of metals, especially of metals of a high degree of hardness. The Council will consider annually all communications received, and may then award a prize or prizes. But in January, 1922, the offer of prizes will be withdrawn, and any unexpended balance of the Prize Fund will be diverted to any other purposes to be determined at the discretion of the Council. Particulars can be obtained from the Secretary.

### A NOVEL BOX CAR LOADER

The loading of such material as sand and gravel into box cars has been necessary on account of the shortage of gondola cars. Many shippers do not have a large enough plant to justify the expense of installing any of the large box car loaders which are on the market, but do not want to incur the loss of time and money required by hand power with shovels and wheelbarrows and there is also a shortage of laborers to contend with.

The box car loader shown in the illustration consists of an inexpensive portable belt conveyor, provided with electric or gasoline motor and receiving hopper, all self-contained and easily wheeled into the doorway of a box car, into a position where the material can be delivered from an overhead chute into the loader hopper, to be thrown by the rapid moving belt into any portions of the car by directing the discharge end of the loader accordingly.

NOVEL BOX CAR LOADER

The capacity of this labor saving device is 80 to 100 tons per hour and with this loader two men can load one box car in 35 minutes. On a recent test two men loaded 80 box cars in six days and it would have taken a great deal longer time if they had used shovels and wheelbarrows instead.

### ACCIDENT PREVENTION

By J. Hamilton

Industrial accidents must always be recognized as one of the possible factors in any mechanical development or enterprise. Much has been done during the past, particularly in recent years, to minimize the casualties resulting from inexperience, carelessness or accidental causes. It is safe to say that the greater proportion of accidents to industrial workers has resulted from individual carelessness or thoughtlessness, either on the part of the injured workman or some other party. Close study on the part of officials and safety supervisors —relative to the causes and prevention of accidents—has resulted in the adoption of many appliances that have assisted in reducing the size of the casualty lists in industrial establishments.

The efficiency of the majority of these devices, however, depends very largely on whether the same are acceptable to the workmen, who are required to adapt themselves to the changed conditions. It is invariably true that the application of a safety device will, for a time at least, prevent the operator from maintaining his accustomed production, and should he be working on a piecework basis, the loss very often develops an antagonistic feeling towards the appliance indirectly responsible, so that it will not receive the just trial it is reasonably entitled to. Frequently the device is discarded as an obstruction to production until another mishap demands its further application.

When guards are mentioned as a means of reducing or preventing accidents we naturally think of some tangible appliance for the purpose intended, but the most efficient guard for permanent results has been acknowledged as the better education of the workmen respecting the serious possibilities that may arise through careless or thoughtless performance of their respective duties. This does not imply that instruction should take the place of safety appliances, but rather that the adoption of such devices should be preceded by personal consultation with the workman upon whose machine the method is to be applied. The conversation should be such as to impress the operator with the need of the device, and at the same time make him feel that his interests are being considered; obtaining, if possible, any suggestions he has to offer in connection with the design or installation of the attachment. His constant operation of the machine may result in a suggestion that may have been overlooked by the designer, and a slight change made to meet the suggestion of the workman may not only remove an antagonistic tendency but would undoubtedly act as a stimulus for the operator to give the device every opportunity to prove its effectiveness.

### IMPORTANT RADIUM DEVELOPMENT

More than $180,000 worth of radium for use in the sciences has been delivered to the Bureau of Mines at Washington [illegible] National Radium Institute to develop a more efficient process for the manufacture of radium out of the carnotite ores of Colorado and Utah. It is stated that the amount of radium in question was procured for an expenditure of less than $38,000. In addition, under the agreement, the bureau has turned over to the National Radium Institute about 6½ grams of radium, and has given to the country a method for producing pure radium compound from the ore for one-third the current price of radium.

When the Bureau of Mines began this work in 1912, it found that the precious carnotite ores, constituting the largest known supply of radium ore in the world, was going to Europe, mainly to Germany where it was being turned into radium and sold back to the United States at fabulous prices.

THE special physical and chemical properties of platinum render a perfect substitute a practical impossibility, but recent investigation has produced several alloys which are satisfactory for certain purposes. The only metals which come into consideration as useful alloys with platinum are iridium, palladium, gold and silver. Iridium and palladium are so rare and are so difficult to work that they are practically excluded and silver is too readily attacked by acids. Thus there remains only gold and palladium, but by alloying the three metals in various proportions a number of useful products have been given the name of "Rhotanium."

IT IS estimated that if the United States send overseas an army of 5,000,000 men and have as reserve 1,000,000 more in the training camps they must, at a conservative estimate, have four adult persons—men or women—in productive pursuits to equip and supply each one of these soldiers in uniform. That is, for the 6,000,000 soldiers in the fighting army they must have 24,000,000 adults in agriculture and manufacture. These two sums total 30,000,000 persons. Discounting the young and the aged, the sick and the infirm, the insane and the defectives, it is probable that these 30,000,000 persons will constitute at least one half of all the American population, that would be of any value whatever for the prosecution of the war.

A SWEDISH firm of Diesel motor builders has made successful experiments in the use of wood distillation products as a substitute for oil for use in internal combustion engines.

## SPECIAL SHELL GAUGES

By M. H. Potter

THE following remarks pertain to some simple gauges, both for production and inspection, which have given satisfaction in service.

### Base Thickness and Over-All Length

Fig. 1.—Working gauge for thickness of base of shell (either for rough or finished thickness). A marking gauge that center punches the shell, enabling the operator on the cut-off machine or base-facing lathe to know exactly how much stock to remove. By means of the handle A the end of the gauge B is forced against the base (inside) of the shell, then by use of a hammer the shell is center-punched in three or four different places so as to enable the operator to locate one of the punch marks readily. The prongs C and D are bent circular to fit around the body of the shell. The center punch E is held in the gauge proper by means of set screws in a groove in the center punch as shown. By making the obvious changes, i.e., placing the center punch forward, this gauge can be used for the over-all length of shell from bottom of base.

Fig. 2.—Shows an inspection gauge to be used after the same operation as a check upon the operator. A similar gauge for the over-all length of the shell would be the same but have a notch cut forward in the required distance.

Fig. 3.—Shows a somewhat similar gauge for checking the over-all length. A similar gauge equipped with a center punch could be used previously for marking to length.

Fig. 4.—A different type of inspection gauge for the base thickness. The piece A is reamed to slide along B. The line C (on the gauge proper) being the high limit of base thickness and the line D (also on the gauge proper) being the low limit. If the base is machined to a correct thickness, the line E (on the slide A) will come between C and D.

### Gauge for Wall Thickness

Fig. 5.—A multiplying caliper gauge having a roller A at one end and a sliding pointer B at the other (the pointer is forced towards the roller by means of a coil spring wound around it (not shown in Fig. 5). The line C is the low limit of wall thickness and the line D the high limit. The pointer E comes between the lines C and D when the wall is machined to a correct dimension.

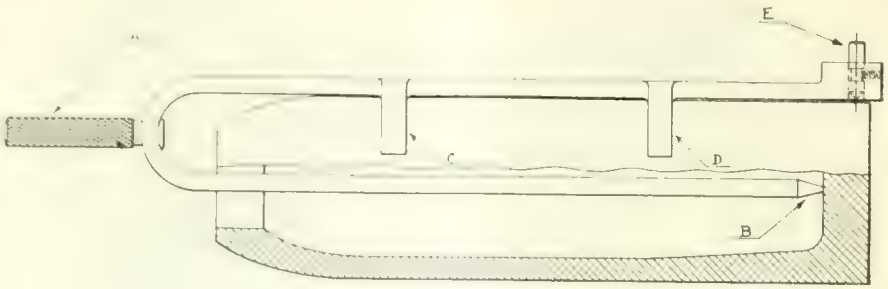

FIG. 1—GAUGE USED FOR MARKING BASE THICKNESS.

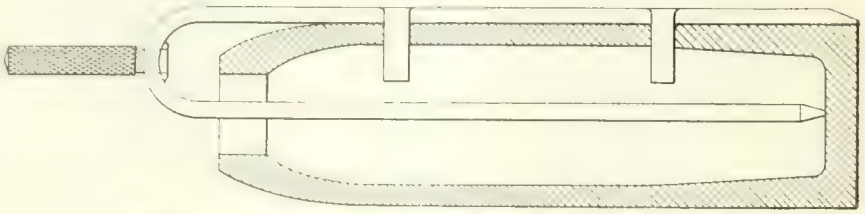

FIG. 2 GAUGE USED FOR INSPECTING BASE THICKNESS.

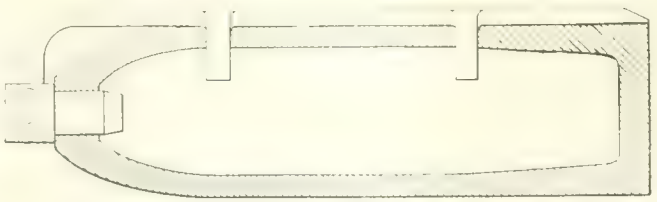

FIG. 3—GAUGE USED FOR CHECKING OVER ALL LENGTH.

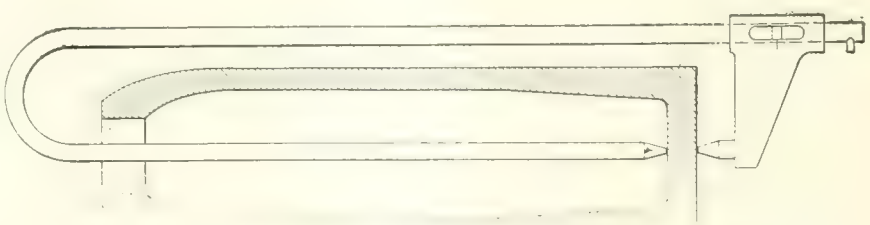

FIG. 4.—ANOTHER TYPE OF GAUGE USED FOR CHECKING BASE THICKNESS.

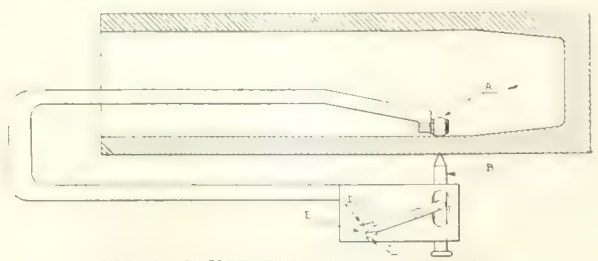

FIG. 5—GAUGE FOR WALL THICKNESS.

**Fuze Hole Concentricity (Before Threading)**

Fig. 6.—The shell is placed against the stop A on the rollers B, C, D and E. A blow, and to enable the workman to follow the taper or belly of the blank is provided by the screw passing through the frame F and acting on the [illegible]

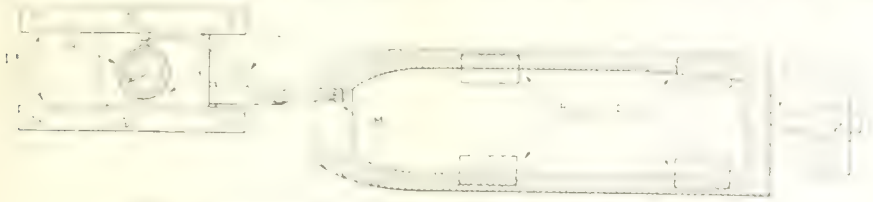

FIG. 6—DEVICE FOR TESTING FUSE HOLE CONCENTRICITY

A standard dial gauge G is mounted on the block H, which has a "V" machined at its base to match the "V" slide strips I and K. The multiplying lever L carries the roller M.

The shell is revolved slowly by hand, any variations from a true bore are indicated by the gauge.

A somewhat similar gauge to determine the concentricity of the bore (bore proper of shell) is a great help in terminating discussions as to eccentric-bored shells.

## INTERESTING WORK ON FILE MACHINERY

By H. Middleton.

File teeth are formed by rapidly driving a chisel into the steel blank which is carried along on a table at a rate proportionate to the spacing of the teeth The teeth might be termed the burr raised by the chisel, for that is what they are—ridges of uniform height thrown up by one face of the chisel point above the level of the blank. A view of the chief working parts of a file cutter is shown in Fig. 1.

Starting with the chisel A, a piece of flat high speed steel, it is seen almost touching the file laid on the half round swivel table B. The chisel is held in the lower end of the hammer H, which is a cast iron block of different weights for different sizes of files. It is the weight of this hammer driven down at a high

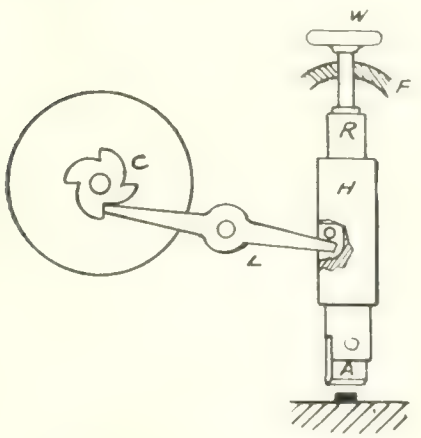

FIG. 1—PRINCIPLE OF FILE CUTTING MACHINE.

rate by the rubber spring R that gives the chisel power to penetrate the blank. A means of up and down adjustment to compensate for slight variations in thickness, to deliver a light or heavy blow, and to enable the workman to follow the taper or belly of the blank is provided by the screw passing through the frame F and acting on the [illegible] R. This is the mechanism of the blow.

To raise the hammer against the resistance of the spring and gravity, a recess is formed in the back of the hammer and a hardened wearing part inserted to receive the lift from the level L which in turn is actuated by the lobes of the cam C. When the lever drops off the highest parts of the cam, the spring R acts and the file receives the blow that forms another tooth.

Some idea of the speed of the machine may be gained when it is stated that the chisel makes nearly two thousand blows a minute on the smaller sizes of files and several hundred blows on the heavier machines where the hammer may be of a hundred pounds weight and the spring correspondingly stiff. The cam, lever, and pin therefore have to be perfectly sound and glass hard to bear up under such conditions.

In one plant where this type of file cutter is used, trouble was experienced with the files showing a slightly wavy appearance though not so bad as to condemn anything but the appearance. A machinist with an investigating turn of mind put some of the files under his magnifying glass and found that every fourth tooth was deeper than its fellows. Tracing this back, he decided that the cam was at fault. When the cam and shaft were put in the lathe the shaft was perfectly true and the rises on the cam very nearly uniform, but a test indicator showed one to be a few thousandths higher than the rest. With a tool post grinder, this high part was taken off, and all made exactly alike, after which the machine did perfect work again. Three of the lobes had been a little softer than the fourth one, which hadn't worn off the fraction that made such a difference in the blow of the hammer.

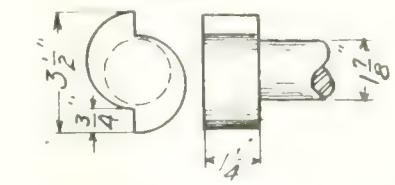
### Types of Hammers

The type of machine previously mentioned is a Hess make. Another type, the Weed, has the cam let in the back of the hammer and raises the latter without the interposing of the lever. Typical dimensions of one of the larger cams and shafts (integral) are given in Fig. 2. Well made in the beginning, they last as long as any part of the machine. Once in a while the machinist is called on to make a new one which he does readily and cheerfully up to the point of hardening.

But the thought of getting the cam not so soft that it will wear, not so hard that it will chip, and at the same time free from warping or a section of strain just back of the cam that will give way during the first week of running—that makes any man think seriously of how to harden the cam and not scrap thirty or forty dollars' worth of labor and material in an instant. Selection of the proper steel, proper treatment during the upsetting of the end, and care in machining go to make up the preliminary precautions. A jobbing shop that has successfully hardened a number of these cam shafts without any special equipment does the work as pictured in Fig. 3.

A pan of water about two feet in diameter is so placed that it comes under a faucet and after the pan has been two-thirds filled the faucet is shut off so it runs in a little stream hardly more than a drip. An overflow hole keeps the water level. A block B is laid in the bottom of the pan to keep the cam off the bottom and accessible to water all

FIG. [illegible]



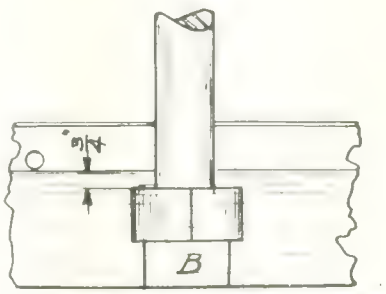


FIG. [illegible] METHOD OF HARDENING CAMS

around. It will be seen that the water extends a little over the cam—enough to insure hardening for the entire width but not preventing the heat in the shaft running down and "drawing" the shaft free from snap and presumably drawing the filleted corner and adjacent centre of the cam.

Some of these cams so hardened have been in daily service for a number of years raising hundred pound hammers and their lasting qualities give silent proof of the correctness of the hardening method.

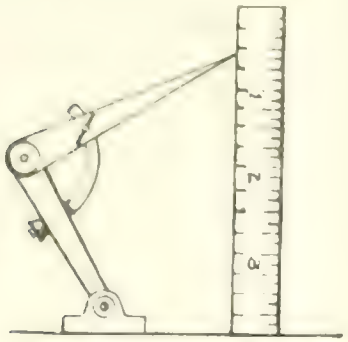
## A SETTING TOOL FOR THE AUTOMATIC

By D. A. Hampson

On many screw machines it is difficult to make a direct setting of tools from certain working faces. For instance, it is desired to set a turning tool ½ in. ahead of a drill and two other tools at definite distances from these, but because the tool holder in the slide is larger a rule cannot be used, for the eye does not span the gap with sufficient accuracy. Often a surface gauge is used in setting up, resting the base on the machined face of either the head or the tool slide and setting the

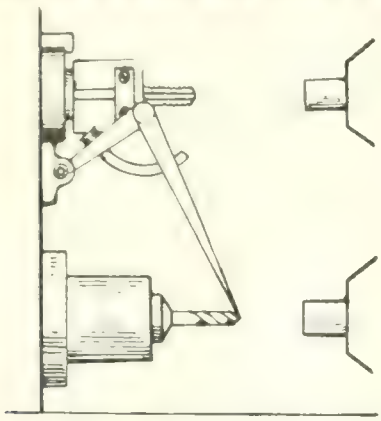
face plate first.

... enough to give footing for the surface ... in Fig. 2. The tool is a converted car- ... in. is drilled and slotted to receive one leg which has been formed into an eye



SETTING THE TOOL TO A RULE

and a binder screw supplied to tighten in any position desired. A base of this size is broad enough to provide stability yet is of a size and shape to slip into a working position between tool holders or the nose pieces of the head if used from that side. In Fig. 1 the divider is ... set to a rule, and in Fig. 2 the



SETTING A DRILL WITH THE TOOL

drill is being located the proper distance out to bring it in the desired relation to the other tools.

## CENTRES IN GRINDING WORK

By Howard W. Dunbar.

The importance of the centre hole in grinding work demands more than passing attention, in fact these holes should be made as accurately as the centre itself in the machine. Too much importance cannot be placed upon the refinement in the centre holes for ground work. The angle of the hole should agree exactly with the angle of the centre that the hole is to rest in. The shape of the hole should be as perfect as it is practical to make it, for no work can be ground any more perfect than the holes that fit the centres the work revolves on while grinding. If they are incorrectly balanced, out of shape or poorly made, the quality of work will correspond with the inaccuracies in the centre holes. The surface that rests on the centre points in these centre holes should be as smooth and as free from chatters and imperfections as they can be made. Slight chatters in the centre holes will be reflected in the ground surface.

Depressions and lumps on these surfaces will tell their story every time in the ground piece. The hole should be deep and the drill relief at the bottom should extend far enough in to give ample clearance for the centre point, so that the centre point will not bottom on the centre hole while grinding.

Foreign substance in the lubricating medium used in centre holes should be entirely removed. Dust, dirt, grit, chips, small pieces of steel, etc., that find their way into white lead, red lead, oil or lubricating compounds will spell disaster in much of the ground work where exceptionally fine finish is desired. The burrs on the edges of centre holes, after the centre hole has been machined and reamed, should be entirely removed for frequently these little burrs are turned over into the centre hole and are the cause for failure when the grinding machine operator attempts to finish.

The size of the hole should come in for due consideration. In all instances the size of the hole should correspond to the size of the centre used in the machine. If a 1-inch centre is placed in a machine, the centre hole in the work should, in a great many instances, be as large as ½-inch, the size of the piece, of course, playing an important part in deiding just what size holes are neessary. Heavy work should not be supported on the points of centres but weli back on their bodies.

Refinement in practically all instances comes from attention to these small details.—*Grits and Grinds.*

## 7-IN. STEEL PLATE IN ROLLS

By L. Street.

It is practically certain that before long thin steel plates, and what is generally known as "tinplate" will be obtainable in continuous rolls of any required length for roofing, lining and other purposes. A power-driven automatic soldering press has been devised whereby sheets of metal can be joined, soldered and wrapped into a roll similarly to the operation performed by a paper or felt-tarring machine. The machine in its present form consists of two presses or dies that act simultaneously. One of these is heated by either gas or electrical energy, according to whichever is the more convenient, whilst the other is provided with a water-cooling arrangement. Both these dies are mounted in a single frame, and are provided with rollers working on cams which bring the does together at intervals. The moment they come together they are acted on by a toggle with enormous force. The sheets are first passed through a subsidiary press, which turns the two opposite angles into a lock. They are then fed into this big press, the edges being locked in place by the machine minder by merely hooking the lip of one plate into that of the one which is at the moment in the machine. The cycle of operations is that the first locked edge comes between the hot dies and is clamped home and soldered if tinplate is being dealt with. The moment this is done the sheet passes on throughout its width and the joint just made is then between the water-cooled dies, by which it is thoroughly cooled. At the moment that this is being done the second joint has arrived between the hot dies, and is being clamped together. This operation is continuous, so long as the sheets, hand-locked together, are fed into the machine. The movement of the sheet is controlled by a stop that holds it stationary whilst the dies come together and allow it to move on the requisite distance so soon as the pressure is removed. After the seam is made the sheet passes through a pair of rollers which give it an upward curve. It is then pressed against spring controlled rollers, which force it into a roll. In another form of machine the sheet passes through drawing rollers on to a reel, by which it can be wound up into bobbin shape. One man can work the machine, and when soldering is going on the flux and solder is applied automatically to the joint in the same manner as in the can-making machines. The capacity of the machine is four seams per minute or twenty boxes of tinplate per day. It is claimed that by the use of this machine a better and more durable seam can be made than by hand, and when soldering is done the metal penetrates the seam uniformly and makes an even and durable joint. It would not seem a difficult matter to produce a machine that would electrically weld together the edges of plates passed into it. It might be suggested that the edges of the plates could be each reduced 50 per cent. in thickness for a quarter, or three-eighths of an inch, where they overlapped, in which case the weld would be the same thickness as the rest of the plate and the whole roll produced would be perfectly smooth and even.

WITH the revolving smooth steel discs now being used for cutting metals, the actual cutting is, says the "Ironmonger," not effected, as was formerly understood, by removing the metal, but by the heat generated by the friction which is so great that the metal is melted at the point of contact. The disc has consequently only to discard the molten metal, and by doing so clears the dividing groove. Naturally the steel disc also becomes heated in the operation, but as the greater part of its circumference is always out of contact, and continuously being cooled by air, and as friction for each point of the disc circumference only lasts for a minute fraction of a second, its own heat remains always below melting point.

**A. J. Reid** has been appointed Hamilton representative for the Armstrong, Whitworth Co., of Canada.

# Corrosion of Iron and Steel, and Its Prevention--V.

By Abe Winters

RUST-proofing by the immersion of iron or steel in phosphorized solutions has proven very satisfactory for many purposes, but, as is the case with many other very excellent ideas, the process is not adapted to all requirements met with in the various industries. The process of phosphorizing iron or steel surfaces consists of two essential operations, namely: (1) Preparing the iron or steel surface. All scale or non-metallic substance must be removed and the surface must be as clean as for high grade enamelling. All metal coatings, such as nickel, copper, brass, zinc, tin, etc., must be removed. The surface of the article to be treated must be ferrous and chemically clean. Sand blast or pickle is used for this purpose; sand blast is preferable; (2) The rust-proofing process consists of immersing the iron or steel in a very dilute aqueous solution of phosphoric acid, manganese dioxide and ferric oxide. The solution as employed is 90 per cent water. The solution is maintained at 212 degrees Fah. during the entire processing of metal. Boiling increases the action of the solution on the metal by reason of agitation. Baffle plates are used in the tanks to obtain a proper circulation of the solution over the metal surfaces being treated.

When the iron or steel is first immersed in the solution a very copious flow of gas issues from the pores of the metal. The amount of gas liberated depends upon the quantity of chemicals in the solution, the temperature of the bath, and the porosity of the metal being treated. The evolution of gas continues until the surface of the metal is entirely converted into a mixture of the ferrous and ferric phosphates, then the action ceases and the operation is finished.

### Proportions of Chemicals Used

The proportions of chemicals required for a bath are 75 per cent phosphoric acid to 1 per cent manganese dioxide and ferric oxide mixture, the latter chemicals accumulate at the bottom of the tank under the baffle plates from which it is removed and thrown away; the phosphoric acid employed by firms operating certain patented phosphorizing processes weighs 22½ oz. per pint. One pint will acidify one thousand gallons of water to 1 point as per NaOH test for acidity; 14.5 points is considered normal acidity, or 20.35 lbs are required to raise 1,000 gallons of water to 14.5 points.

The first chemical cost per 1,000 gallons equals $3.67. Additions of fresh acid must be made before beginning each batch. Then the solution is tested for acidity and the normal point acquired. The average cost of operation approximates $40.00 to $50.00 per ton if chemicals are purchased from the patentee, but this would be greatly reduced if they were procured in open market.

The time of treatment varies from 1 hour to 8 hours. No electric current is used, the process being one of simple immersion in a boiling solution of the proper quantity of previously mentioned chemicals. The processing solution is tested as follows: 10 c.c. of processing solution is taken in a beaker, 5 drops phenolphthalein added as an indicator and the solution filtrated with a one-tenth normal solution of sodium hydroxide (NaOH); 8 oz. of manganese dioxide ($MnO_2$) is required to each pint of the acid solution.

### Penetration

When iron or steel is immersed in the boiling solution an action takes place upon the surface of the metal and is indicated by the liberation of hydrogen, the treatment continues until all action ceases or the hydrogen is no longer liberated. The theory of this action is that the ferrous surface is gradually converted to a ferric condition and becomes coated with an insoluble basic phosphate of iron. The action of the solution upon the metal or at least the evolution of hydrogen is much more pronounced in the case of cast iron than with sheet steel, and the harder the steel the less intense is the action, and the time required for processing is increased. A penetration of .004 inch is claimed for this process. The writer has conducted several tests to determine the accuracy of this claim and has failed to obtain a case which verifies the statement. A magnification of 330 diameters does not reveal any appreciable penetration. Furthermore, the temperature of the metal in process is never more than 215 degrees Fah., and we fail to understand how this temperature can open the pores of hard steel sufficiently to permit of a .004 penetration by the acid solution. A penetration of .004 inch may be possible in grey iron castings if the treatment were given under ideal conditions.

These phosphorized metal surfaces are not resistant to friction, running boards of automobiles, handle bars of bicycles, etc., quickly becomes a prey to rust where worn by the feet and hands of the persons using the vehicles. The phosphorized rust-proofing treatment is said to prevent the spread of rust if a portion of the metal surface is exposed. Tests by responsible persons in various localities do not confirm this claim, and as the penetration in average cases does not exceed .001 inch it is obvious that there is no resistance to spread of rust at points where the surface coating has been removed by a sharp-edged article.

### Electro-Plating Impossible on Phosphorized Surfaces

Certain promotors of phosphoric acid rust-proofing have emphatically declared that phosphorized surfaces can be electro-plated. This claim has naturally attracted the manufacturer of plated wares as it appeared to be a short cut to durable and rust-proof plated surfaces on iron and steel. To any who have been thus informed we would say, go slow, as iron or steel surfaces which have been processed by immersion in rust-proofing solutions containing phosphoric acid, manganese dioxide and ferro oxide cannot be electro-plated with any metal in any solution, because the film produced over the surface of the metal is a non-conductor; the iron or steel is very effectively insulated and absolutely protected as far as electrolysis in the plating bath is concerned.

If the surface film is removed electro-plating is possible, but the protection afforded by the rust-proofing is destroyed, as no appreciable penetration is effected, therefore the phosphoric acid and manganese dioxide treatment of iron or steel is not adapted to such goods as are to receive a subsequent coating of metal by electro-deposition. We are not aware of any firm using the phosphoric acid process for rust-proofing steel and relying on the simple process alone for efficient protection to iron or steel.

In every case the processed metal is given a final coating of either oil, wax, paint, japan or enamel, the most enthusiastic advocate of phosphorized metal surfaces which the writer has met admitted that all processed metal should be given the protection afforded by the previously mentioned substances. As stated previously the rust-proofing of iron or steel by treatment in solutions of phosphoric acid, manganese dioxide and ferric oxide has proven very satisfactory for many purposes, but is not adapted for the general requirements of metal protection. The process is expensive if operated efficiently. Stove

manufacturers have regarded the process with considerable doubt for several [illegible] are practically condemning [illegible] of no value as a prevention against rust on stoves, ovens or cast iron which is subjected to excessive heat

Strong Solutions Detrimental

Another objection to the process is the inefficient protection which results from treatment in solutions which have been loaded in excess of the chemical capacity, [illegible] fully 50 per cent of their product was thus treated. The process does not require a skilled operator but it is essential that he should be [illegible] of a fair degree of horse sense.

The writer has pieces of steel undergoing atmospheric exposure tests, these have been treated by various rust-proofing processes and the result of the test is at present favorable to no particular method where phospheric acid is used. At present our conclusions relative to these phosphorized surfaces is as follows.

That the repellant nature of the surface of iron or steel toward rust is increased by proper treatment in aqueous solutions containing phosphoric acid, manganese dioxide and ferric acid is unquestioned, wrought iron and steel of various methods of manufacture are greatly influenced in corrodibility by the amount of phosphorous contained in them. With one per cent. of phosphorous present the corrosion is a little over one half as great as in cases where the iron is free from phosphorous. If two pieces of steel containing different percentages of phosphorous are immersed in salt water, in contact, the low phosphorous specimen will corrode more rapidly that the high grade metal. Iron alloyed with chromium, cobalt or nickel will resist corrosion in a similar manner.

If phosphorous acts as a deterrent to corrosion when introduced into an alloy it is reasonable to expect that an insoluble film of basic phosphate of iron over the surface of ferrous metals would repel corrosion more or less. The effectiveness of such films naturally depending upon the nature of the vehicle in which the film was produced, the manner of treating the metal and time allowed for processing. "Rust once established, carries within itself the elements of a ceaseless life; even in a glass bottle rust begets rust."

## HEAT-RESISTING PAINTS

By Mark Meredith.

The best heat-resisting paints are made from hardened asphaltum or pitch, dissolved in a fluid solvent; whilst for temperatures below the boiling water, casein, animal albumin and alkali silicates have given good results, writes a German authority. Pyroxylin varnish is very durable, but browns when heated, and can only be used when in admixture with black body colors. The following preparations are worthy of mention.

Roman Prasser's Recipe.—Equal parts (40) of pigment and spirit varnish (composed of 1 part of bleached [illegible] 7 parts of spirit) are intimately mixed with 1 part of camphor and 5 parts of bleached oil varnish. The article to be coated is brushed over several times with a mixture of gypsum and spirit varnish, flatted and painted over with the above preparation, being finally polished lightly with shellac varnish. This paint will stand the heat of boiling water for some time, but browns on prolonged exposure and peels off.

G. M. Neisel's Recipe.—Solid fats or fatty acids are distilled at 250 to 300 deg. C. with superheated steam. The residue being mixed with about 10 per cent. of red lead and 2 per cent. of litharge, treated with superheated steam at 400 to 500 deg. C. and thinned down at 150 to 200 deg. C. to workable consistency with linseed oil. As an alternative method the dilution with linseed oil is replaced by blowing in 25 per cent. of petroleum vapor, and then diluting with the crude benzol or other dilutent when sufficiently cool. The product is said to dry with a glossy surface, and to stand a dry heat of 500 deg. C. or damp heat up to 250 deg. C. As a matter of fact, an asphaltic substance and especially the distillation residues from fats (bone pitch, etc.) are capable of resisting high temperatures, and are used for stoving enamels.

Meyer's Recipe.—Residues from the distillation of fatty acids are heated to about 500 deg. C. with lead oxide and lead peroxide for three to four hours until thoroughly combined, the mass being dissolved in mineral oil and thinned down with turpes.

Bethisy's Recipe.—The mass consists of nitro-cellulose and a solution of calcium chloride in amyl acetate, with an addition of ether, alcohol, alum, talc, asbestos or mica, elasticity being imparted by vaseline oil or lavender. Celluloid varnishes are capable of standing a certain amount of heat.

Selmay Meyer's Recipe.—A heat-resisting varnish for iron ware, especially iron stoves, etc., is prepared by mixing powdered liver of sulphur, cyanide of potash, bicarbonate of soda, and sufficient cassel brown to give the desired color, and the mixture is saturated with alcohol. The pulp is passed through a sieve to remove coarse particles, and after being applied to the metal is exposed to a temperature of 200 to 300 degrees C. Other fireproof pigments may be submitted for the brown. This preparation is an enamel rather than a paint, but will stand heat very well.

Syracuse Tar.—A mixture of finely ground alum, asbestos and borax or boric acid is stirred into melted coal tar, the proportions being 60 to 65 or 40 to 50 parts of tar, 8 to 4 to 2 to 8 of alum, 20 to 5 or 38 to 30 of boric acid, 12 to 5 or 20 to 13 of borax, and 5 to 8 of asbestos. The idea seems to be that the salts will sinter together under the influence of the heat, the tar being presumably carbonized.

Avenarius' Recipe.—Ten parts of alkali silicate are heated under pressure with 25 parts of casein, a pasty mass being formed. This liquid is mixed with 0.2 part of carbonate of magnesia and 0.1 parts of borax, to increase the heat-resisting properties, whereupon 0.15 part of zinc oxide, 0.3 part of sodium phosphate and a suitable quantity of lime and earthly pigment is added to give covering power. For use, the mass is thinned with boiling water, and is said to stand a temperature of 100 deg. C. (212 deg. F.).

Fairweather's Recipe.—Equal parts of silicon carbide and semi-fluid alkali silicate are mixed together, 3 to 10 per cent. of chalk being added.

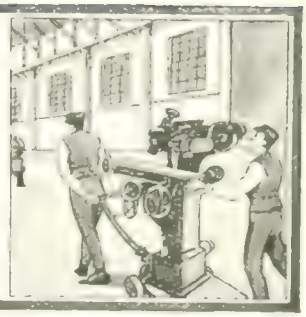
Hall's Fireproof Recipe.—This paint consists of moist silicate of magnesia, 5½ of dextrin, 5½ of gypsum, 2 of chalk, 2 of alum, and 1 of common salt. Four parts of this powder are mixed with three of boiling water for use. This preparation and the preceding one owe their "fire-resisting" properties to the sintering of the salts when heated.

Eymer's fireproof varnish is compounded of a mixture of alkali silicates with asbestos or other fireproof material and vegetable or mineral oils, or oily substances like glycerine.

Give a couple of coats of a good washable distemper, upon which should be given two coats of oil paint, the first somewhat flat and the last with a little oak varnish added to it. Painting on galvanized iron is at all times difficult, and there are various preparations on the market specially made for the purpose. If you do not care for the water paint plan try the following:—First go over the work with a wire brush so as to roughen the surface, then apply a coat of red lead well brushed out and mixed thin with boiled oil and turpentine. You will, of course, only mix just sufficient quantity of the red lead for the job, and will take care to stir from time to time while in use, as the red lead sets quickly. If there is much of the work to be done, we should recommend you to use orange lead instead of red lead, as although the two are practically of the same nature, the orange lead is a good deal lighter, and hence does not settle so quickly. You may take it that everything despends on the priming coat, and if this is satisfactory, the two or three coats upon it will hold well. The washable distemper in our experience gives as good a result as anything, and is much cheaper than the red lead system, but you might—having decided upon which you will use—paint just a small portion by the other method for the sake of experiment, and see how they look at the end of the year or so.

THE INTAKE conduit for an air compressor should be made of non-conducting material such as wood, brick or concrete, and should draw air from the coolest place available, never from the compressor room itself. The cross-sectional area of the conduit should be equal to at least one half of the area of the piston in order that the air may flow with perfect freedom. In hot and dusty localities it has been found beneficial to draw air from the interior of a framework continuously drenched with water. This arrangement not only cools the air but removes the dust at the same time.

# DEVELOPMENTS IN SHOP EQUIPMENT



*Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

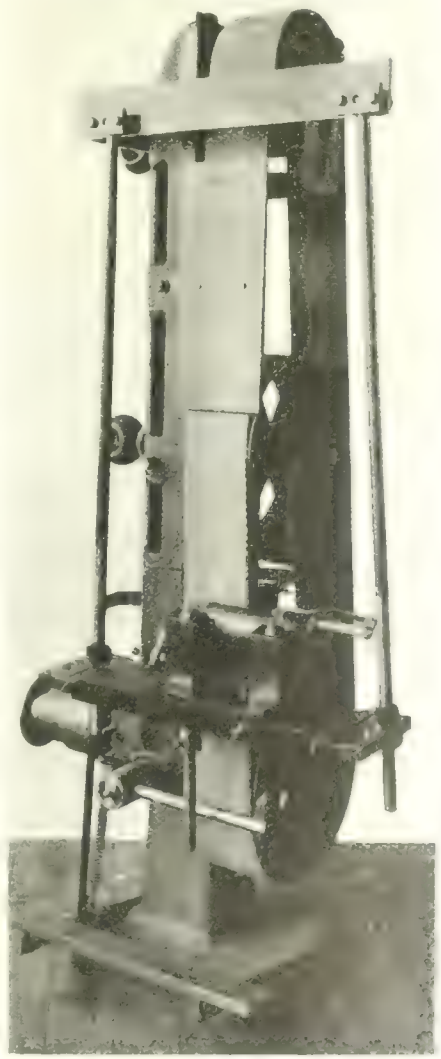
## POLISHING AND FINISHING MACHINES

THE polishing and finishing machines developed by the Blevney Machine Co., Greenfield, Mass., make use of a two-belt system of finishing with an abrasive cloth belt running at high speed over a heavy corrugated leather cushion belt. Skilled labor is unnecessary and the process results in a remarkably high rate of production.

The Type A machine is built up on a heavy cast iron column providing the necessary rigidity for a high-speed machine. Steel ways are attached to the column and the sliding frames in which the idler pulleys operate travel on these ways. The main belt pulley is attached to a shaft running in suitable boxes in the lower part of the column of machine and the driving pulley is attached to the other end of this shaft. The patent cushion belt is run over the main pulley and the idler next above, travelling at a speed of 7,000 feet per minute. The cloth abrasive finishing belt is placed over the cushion belt running from the main pulley to another idler pulley operating in frame at top of machine. The idler pulley frames in both cases are governed by weighted levers having a fulcrum journaled wheel, and a steel pinion forms connection with a steel rack attached to the frame. These weighted levers should be in a horizontal position when the machine is in operation and to bring the levers to this position a spring is provided holding the pinions in engagement with the rack. By pulling the fulcrum against the action of this spring the pinion will become disengaged and the lever may be moved to any desired position, the spring restoring the engagement between pinion and rack.

The alignment of the two belts may be controlled by means of hand wheels operating on the idler pulley boxes, these wheels serving to tilt the pulleys so that the position of the belts may be changed as desired.

A suitable table or stock rest is provided for holding the stock and for the application of fixtures and attachments. A spring platen or pressure bar is applied back of the cushion and finishing belts. The action of this pressure platen is controlled by a foot treadle and stops are furnished to limit the forward and return movement. The face of the platen is made to suit the work to be finished, thus, for plain flat work the platen has a plain face, while for finishing tubes or round pieces parallel strips are placed at top and bottom of platen, causing the belt to curve around the circumference of the stock being finished. Where desired the platen may be made sectional at a slight additional cost over regular construction, or special rotating platens with yielding centres can be furnished.



TYPE A PARALLEL [illegible] AND FLEXIBLE [illegible] MACHINE

The adaptability of this machine to a wide variety of work is illustrated in the accompanying engravings. Fig. 1 shows the machine set up for the finishing of tubing.

Fig. 2 shows the machine set up for the grinding of the bourrelet on shells, resulting in exceptionally fast production.

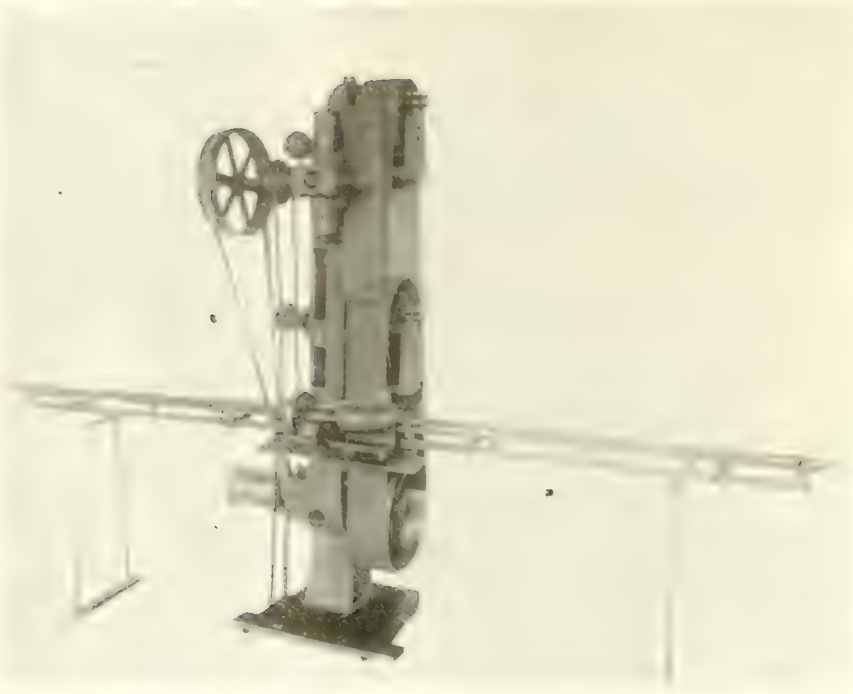
A special set up is shown in Fig. 3 for the grinding of torpedo heads and afterbodies, this method having reduced the finishing time from 17 hours to less than 50 minutes.

The production of these machines is obtained through the medium of the two-belt system. The corrugated leather cushion belt runs at 7,000 feet per minute and the abrasive finishing belt which runs over it runs at a slightly increased speed, due to the enlargement of the effective diameter of the driving pulley amounting to twice the thickness of the leather cushion belt. The increased travel amounts to about 1½ inches on each revolution of the main pulley.

The increased speed of the cloth abrasive belt is neutralized in operation when pressure is applied behind the belts, with the result that the travel of the abrasive belt is somewhat retarded at point of work so that it must curve into high and low sections following the corrugations in the cushion leather belt. In this manner are obtained high points for cutting and low points for chip recess. After the belt passes point where work is held it expels the chips and resumes its normal position.

The chips are disposed of immediately as generated or cut, while in other processes the chips are rolled along over the face of the work, thus scratching or damaging work already done and causing unnecessary friction and heat. It will be seen that the two-belt system of polishing and finishing does away with unnecessary friction and thereby immediately provides for faster finishing, and at the same time a higher and more satisfactory finish.

A jointing machine is used in making the abrasive belts endless and the method employed is such that the thickness is practically no greater at joint than at any other part of the belt, this process not only makes an exceedingly strong belt, but one which runs



TYPE A MACHINE FITTED WITH TUBE TABLE AND POWER FEED

smoothly and evenly and does not jump over the work at the joint.

The abrasive belts as they become used are later dressed down for finishing in various stages until they are finally used for greased belts for the finest finishing. In this manner the life of a belt is extended to where the item of cost is hardly a point for consideration.

The cloth abrasive belts as compared with an ordinary buffing wheel do away with all centrifugal action upon the finishing grains where they are under strain and as compared with the disc grinder they provide a uniform speed for each cutting grain, the disc grinder grains being subject to different speeds on account of their location at different points from centre of disc. It is also well to note that there is no loss in abrasive material through the use of the cloth finishing belts, while a considerable portion of the abrasive grain is lost in operation on the ordinary hard wheels and discs.

## HIGH GRADE PLANERS

The Liberty Machine Tool Co., Hamilton, Ohio, have recently completed their new plant and one of the recent products is illustrated herewith.

The 36-inch planer shown has been designed to meet the requirements of modern practice and includes the safety appliances and conveniences necessary for safe operation. The machine has no parts extending below the floor line; therefore no special foundation is necessary.

The bed extending to the floor affords a solid foundation for the machine. The top is closed between the vees except at the gearing section which is heavily reinforced by heavy girts. All holes are drilled from jigs, insuring accuracy.

The gearing is placed inside the bed and is easily accessible from the top. The gears are pressed onto the hubs of the pinions, relieving the shafts of all torsional strains. Heavy shafts support the gearing and journal in wick oil bearings. The pulley or driving shaft is journaled in bronze oiling bearings and has an additional support outside of the pulleys. The driving pulleys are made of aluminum. The loose pulleys have wick oiling bronze bushes and solid web instead of arms, to insure the safety of the operator. Wide belts insure ample driving power.

The table of liberal proportions is provided with excellent oiling facilities. A simple and efficient shifting mechanism responds to the will of the operator.

The housings, substantially built, extending to the floor (with large taper plugs for alignment and bolts for fastening to the bed) are of box section and capable of withstanding the strains peculiar to this member. Pads are provided for attaching motor brackets at any time.

The rail is of deep box section and is made long enough for two heads. The heads are made right and left for close range, and are provided with graduations for swivelling up to 90°. The down feed screws under strain are in tension instead of in compression, as is usually the case.

The feed is independently adjustable on either rail or side head and the operator can change the feeds with the machine in motion. A direct reading index dial conveniently located enables him to set the feed to the required amount.

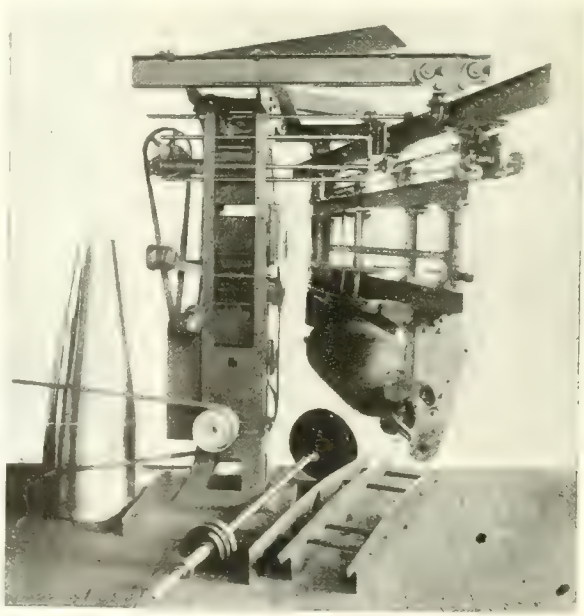
The elevating device is centrally located on the top brace and is operated by a long handle at the side of the housing. All gears are idle when not in use. The side heads are provided with independently adjustable feed, and can be provided with micrometer index collars.

## 20-IN. CRANK SHAFT FLANGE-TURNING LATHE

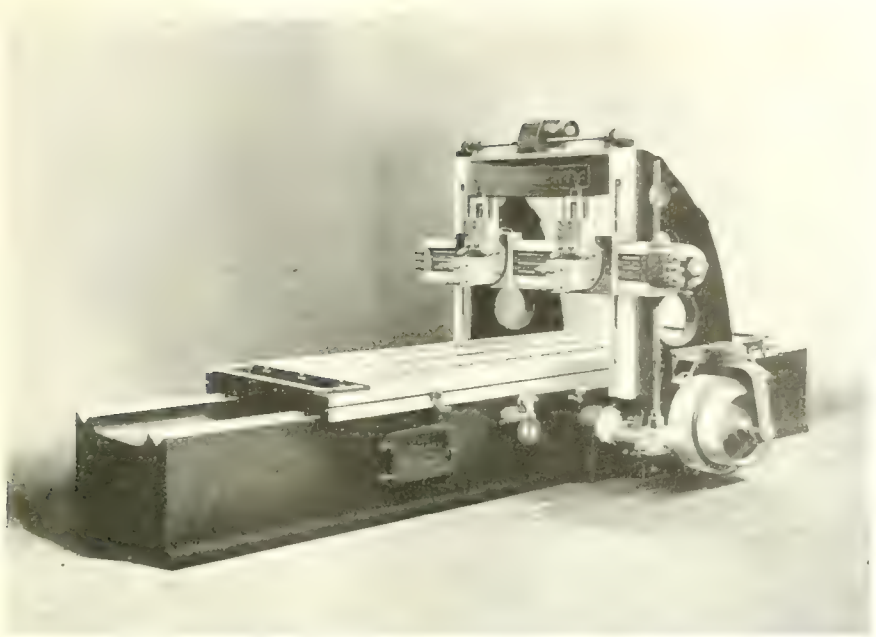
This is a special purpose machine, designed to turn and face the fly-wheel flange of an automatic crank shaft. The spindle is a large iron casting, with a 7 in. hole through its entire length. Properly located in this hollow spindle is a positive dead-center to support the front end of the crankshaft. In order that this center can be located quickly a cone-shaped piece is pressed in the spindle which immediately directs the crankshaft on to the centre.

The shaft is rigidly and accurately held to the face-plate by an adjustable chuck, which is clearly shown in the illustration. The flange end of the crankshaft is supported on a tailstock centre. The tailstock is extra heavy and is fastened to the bed by four large bolts.

A compound tool block is fitted to the rest. Three tools are placed in the required position to turn the flange to its predetermined thickness. These tools face both sides of the flange and turn the fillet at each end of main bearing. There is a secondary tool block, cam mounted, which turns the outside diameter of the flange, while the three other tools are facing. The lathe here pictured is driven by a Westinghouse type SK motor of 10 h.p., 1,100 r.p.m., reduction being accomplished through heavy gearing.



SPECIAL MACHINE ON TORPEDO HEADS AND AFTERBODIES.



HIGH GRADE PLANER

The one-speed and one-feed system is used, as the most advantageous speed and feed have been determined for the work at hand. This machine was designed and manufactured by the Reed-Prentice Company, of Worcester, Mass.

## UNITED STATES IMPORTERS MUST FURNISH IMPORT LICENSE NUMBERS TO CONSULS

THE United States War Trade Board, through its Bureau of Imports, has issued a ruling to United States Consular Agents throughout the world, that on and after May 27, 1918, no consular invoices for any commodity are to be consulted unless the shipper furnishes the consul the number of the United States import license covering the shipment. The only exception to this rule is the case of shipments covered by general import licenses. Already it is necessary for importers to communicate to their shippers abroad the number of the United States import license for articles on the restricted lists before consular invoices can be obtained and shipments started from abroad. The present ruling extends this regulation to all articles, both restricted and unrestricted, except such as are covered by general import licenses. This means that import licenses must be obtained for the importation of all commodities before they leave foreign points. It is believed that this will avoid much uncertainty in the minds of both importers here and consular agents abroad as to what import license numbers must be communicated abroad. It will also give the War Trade Board an opportunity of passing upon all importations from a standpoint of enemy trade connection before shipments are put in transit.

The United States Bureau of Imports will pass promptly on all applications for import licenses, so that, if the license is granted, the importer may be informed immediately of its [illegible] and sent it by mail or cable to [illegible] per abroad.

As intimated above certain classes of importations are permitted to enter under general import licenses; and where these licenses exist it is unnecessary for importers to apply for individual import licenses. These general licenses are designated as "PBF" licenses."

## SPECIALIZATION AND STANDARDIZATION IN GERMAN INDUSTRIES

The Association of German Engineers, on the instigation of the Imperial Ministry of Economics, has declared itself ready to form a Research Committee to investigate the technico-economic questions connected with standardization and specialization in German engineering. The Imperial Ministry of Economics will be represented on this Committee, and will contribute to the costs of it. According to the principles agreed upon between the Association, the Ministry, and representatives of the engineering associations, the committee will occupy itself solely with technico-economic questions to the exclusion of all purely economic problems, such as the distribution of quotas, formulation of prices, etc. Its work will be limited to the sifting, collection, and utilization of the available material on behalf of industrial associations whose members in great majority consider standardization and specialization not only possible but also desirable. The execution of improvements proposed by the committee will be left to the associations themselves.—*Nord-[illegible]*.

## NEW ELEMENT NAMED AFTER PRESIDENT

The first element to be discovered in American ore is a rare radio-active substance which was isolated last year by Roy Franklin Heath and has been found in the sand from the Yukon and British Columbia. It was first discovered and isolated from Montana monazite and granite sand.

The new substance is the 86th element to be discovered and was named Wilsonium in honor of the President of the United States. It resembles radium in some respects but is essentially distinct. So far two grams have been recovered, costing more than $25,000; radium costs are more than double.

The principal uses of Wilsonium so far are in medicine and experimental science.

## PATENT LAW REFORM AN URGENT NECESSITY

"AN Englishman in England cannot get a copy of a Canadian patent without sending to Canada, and even then he gets only a typewritten copy, as patent specifications are not printed there." These are words used by Sir Robert Hadfield, the prominent British manufacturer, in the course of a recent address on Patent Law Reform.

Sir Robert Hadfield is a great enough man to be able to make such a statement without deprecating Canada individually. The breadth of view which he really holds and which he was endeavoring to impart to his hearers was inspired by and limited to the subject of his address.

Uniform patent law throughout the British Empire is a much to be desired state of affairs, and one which would be very influential in its effect upon the future progress of industry, especially such as will be called upon to bear the brunt of future German competition.

The value of judicious patent laws is amply demonstrated by the tremendous inventive activity of the United States, and while the ultimate existence of a patent system of world-wide uniformity is perhaps not practicable nor altogether desirable, the development of a scheme confined to the British Empire and incorporating the most desirable approved features of American practice would work toward the upbuilding of the Empire's components in a most desirable manner.

Mr. Hanbury A. Budden, of Montreal, has addressed the Minister of Agriculture on the subject of Canadian patent specifications and drawings, and his letter, published elsewhere in this issue, sets forth in plain figures a few salient facts concerning the shortcomings of Canadian patent law.

> "A copy of a British patent costs eightpence, while the United States patent office sells copies at five cents apiece.
>
> "A copy of a Canadian patent costs on an average over $2 and can only be obtained after considerable delay."

The shortcomings of Canadian patent law are not widely recognized except among those who have had occasion to touch patent work, but it is in the nature of a national reflection that printed copies should be needed, not only to supply the examiners' files, but also to fulfill an agreement with the United States patent office to exchange copies.

Proper patent laws are as effective in stimulating industrial development as the best industrial commissioner who ever boomed a city. They are more so because their efforts are on behalf of the entire country; they attract foreign capital, they stimulate native genius, they encourage raw material development, and are a continuous and growing advertisement of the country amongst foreign nations.

Intensified competition in the near future will result in a crop of inventions whose benefits will go principally to those nations whose laws encourage their assimilation. At the present day there are more mechanics and manufacturers alive to the value of patents than at any previous period of our history.

Now is the time to bring conditions in line with the most approved ideas. A large percentage of the country's brains keeping the patent future in mind as an active factor in trade competition will do much to insure our successful surmounting of after-war problems. The time to start is now, the harvest is ripening daily.

## REGISTRATION, A DEVELOPMENT OF WAR-TIME CONDITIONS

THE approach of June 22 with the necessity for registration by everyone sixteen years and over brings home to many the seriousness of the times. The taking of a census every ten years is a normal event, but the numbering of a nation as a result of conditions brought about by the war will impress the present occasion as none before.

Industries generally have been in a continued state of apprehension since the demand for men became insistent and the frequent dislocations suffered as a result have borne hardly in several individual cases.

Just how the results of registration will be utilized by the Government have not been made clear. One object, donbtless, is to map out a comprehensive scheme of victualling and fuel supply.

Probabilities of famine on a large scale in Europe during the coming winter are great enough to justify any degree of preparation, and it will be a case, not of how little we can use in Canada, but of how much we can send abroad.

Saturday week's registration is somewhat parallel to the late postal census of manufacturers, and the Government should receive every support in making it as well as in applying the data at a later date to the direction of the country's activities.

## PRACTICAL METHODS OF FUEL CONSERVATION

FACTORY owners in the United States are being actively assisted by the Federal Fuel Administration in the matter of effecting fuel saving.

The question of how much coal a factory can get is not any more important than knowing how to get the most heat from the coal after it is receivel.

The mode of operations is on somewhat similar lines to the "greater production" propaganda recently carried out. A board of competent engineers is recommended to be attached to a conservation committee in each State, while a corps of lecturers will be employed to arouse public interest and disseminate engineering information.

A fifty-minute film of moving pictures will demonstrate good and bad methods of operating steam plants while methods of testing boilers, fuels, etc., will be similarly dealt with.

The prospect of possibly harder times regarding fuel will make all factory owners and power users approve of such missionary work. Despite the prevalence of electric power in most Canadian provinces, the consumption of coal is plenty high enough to make imperative every possible economy of fuel. Where the fuel is used for heating a few degrees less in temperature mean a large difference in the coal consumption.

Many factories are over-heated in winter, necessitating the discard of some clothing by employees. Such conditions are criminal and their continued existence is a betrayal of the country's welfare. Such propaganda as outlined above should bring all parties to a sterner realization of conditions as they will actually be in the coming winter.

Preparedness and Efficiency are indeed the watchwords of the hour.

# HELPING WOUNDED MEN TO EARN THEIR LIVING

**Russell Motor Company, in Co-operation With Government, Have Vocational School in Operation at Present**

MUCH has been said and much has been written about the problem of dealing with the men returning from the front—men who will not be able, by reason of their wounds, to return to their former walks in life. Any person who has had occasion to see the number of returned men already in the country, and who will take the time to think of the numbers who will be coming after them, can easily see that there is a big problem here. The big thing is to avoid training these men in occupations that afford only fitful occupation, or in taking up their time in a line of vocational work for which they have no liking or aptitude.

The Russell Motor Co., acting in conjunction with the Military Hospitals Commission, is doing a very creditable piece of vocational training at one of their branches on Adelaide St. west, where at present some twenty-five machines, commonly used in the ordinary run of shops, are in operation, the idea being to teach returned men under actual working conditions.

### Making Munitions Parts

Arthur Kirky, of the Russell Motor Co., is the instructor in charge of the establishment. Mr. Kirky has had a wide experience as an expert mechanic, and the men coming under his supervision are fortunate. The production of the shop is not the main consideration here, the basic idea being the training of the men, although the work turned out is accurate enough to be used in the filling of munition contracts. Hand screw machines, engine lathes and universal grinders are in operation, and it is on these at present that the efforts of the men are chiefly directed. They are not simply taught the operation of the machine, but the making and setting of their own tools, and the general upkeep of the machine.

### Many Trades There

None of the men at the Russell vocational shop have had previous machine shop training. They have come from other walks in life, and from the nature of their injuries find that they cannot return to them. For instance, among the number at present in the shop are two roofers, plumbers, bricklayer, laborers, etc. The men have all been overseas and through the hospitals. They are now granted vocational training by the government, through the Military Hospitals Commission, as the first step toward fitting them for a return to private life, so that they will not have to depend on any person for charity. Just now the men are turning out base plates for six-inch shells and nose plugs for shrapnel. The pay given to the men is arranged in the first place according to the schedule of the government, regulated by the family, etc., depending on the man. The Russell Co. maintain the shop, pay for power, light and instruction, and when the men have attained a reasonable degree of efficiency in their work they are paid a bonus by the company.

### How it Works Out

It is perhaps too soon to speak definitely of the degree of success that is likely to attend the efforts of the company and the hospital commission. Already three or four men have left the establishment, and two of them are doing general machine shop work now at the Russell plant. The course granted in the first place is from four to six months, and if a man shows any marked aptitude for the work, the instructor applies for an extension to his time, and it is almost invariably granted. In this case he puts the man on to more particular work, and teaches him the rudiments of the tool-making business.

### Using One Arm

Difficulty has been found in securing employment for men with only one arm. In the past the tendency has been to look for clerical or similar work for such a person, but there are a large number of them not fitted for these positions. In one department of the Russell plant an instructor is teaching the one-armed men the making and trueing of bicycle wheels, and the way these men are getting along with this class of work is surprising. Of course once they have mastered the job they do not need to depend on the making of bicycle wheels entirely, as they can turn their hand to making wheels for airplanes and automobiles, in both of which the same principles are applied. The rims, spokes and hubs are applied, and it is up to the students, under the instructor, to assemble and adjust them all properly. One of the returned men was making particularly good use of a mechanical arm, which was doing service for the one he had lost at the front. Of course the movements he was able to make with it were crude as compared to the other member, but he was using it, and with use he will become more expert in its manipulation. Already some of the men who have learned the wheel building are holding positions in the city, and although their speed is less than that of a man with two arms, very favorable reports are being returned to the instructor from the places where they are now employed.

## Recognizing Canada's Position

THE feeling of some of the large American companies toward Canada is well conveyed in actions that come to our notice from time to time. Just last week the Vanadium-Alloys Steel Co. forwarded to the manager of CANADIAN MACHINERY a cheque for $2,500, with the request that it be placed to the credit of the Canadian Red Cross or Patriotic Association. CANADIAN MACHINERY has had the pleasure of forwarding the cheque to the Red Cross. This is not the first time that the Vanadium-Alloys Steel Co. have shown their sympathetic interest in Canada's war efforts, other cheques for similar purposes having been forwarded to this paper and turned over to the proper authorities.

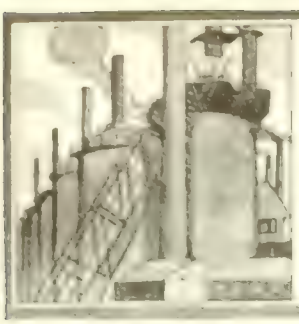
Although the connection of the Vanadium-Alloys Steel Co. with Canada is largely a commercial one through their distribution here of their familiar "Red Cut" high speed steel, there is a deeper feeling than one of business dealings and transactions. This Pittsburgh firm realize and say so openly that Canada was fighting the United States' battle for two years or more before the Republic entered the struggle. It is in plain recognition of this fact that the firm wishes to make a contribution that will strengthen the hands and more freely equip those whose errand of mercy calls them to minister to the hurt and wounded men of the Canadian armies.

The Vanadium-Alloys Steel Co. do not desire to have any publicity attached to the matter. That was their expressed wish, but CANADIAN MACHINERY, realizing the sincerity of their motives, and knowing that they would not be misconstrued by the Canadian public, has taken the privilege of giving this measure of publicity and appreciation to the gift.

The idea that there was always big money made on shell contracts probably got its start from the fact that the men who lost heavily did not care to say very much about it.

* * *

There's not much use trying to get anything in the line of steel without an order, a permit, a license and a certificate. If you go into the market without the full regalia you get poor treatment and poorer service. And the end is not yet by any means. Probably in a month or so from now it will be necessary for the domesticated husband who wants to buy a package of tacks to lay the carpet on the front stairs to show that this is going to aid in the winning of the war.



# MARKET DEVELOPMENTS

# U.S. Will Not Take Over The Steel Plants

## Apparently Satisfied With the Output From the Mills—Canadian Business For War Purposes Will be Protected Under the Latest Ruling—Sheet Prices Tighten This Week as Stock Runs Low

THE hope that has been held out in some quarters that after a month or so of intensive effort on war work at the United States rolling mills there would be steel for commercial purposes is simply vanishing into thin air. Every day sees the war appetite grow, and as the war demand has the undisputed preference, the prospects for commercial interests getting a chance are very poor.

Canadian orders being placed in United States now are feeling the application of the embargo. More than that items that are not on the embargo are being made to feel the ruling, the evident intention being to keep the spirit as well as the letter of the regulations.

Production of basic materials at United States points is proceeding satisfactorily. Of course there are local features that work against the maximum, but in the aggregate it can be said that right now the plants are consistent performers and are registering a full 95 per cent. of their possible capacity. More can not be expected, especially with the warmer weather coming on.

Prices tightened up a little more in the steel trade this week, sheets being the item to feel the tendency. Billets are not being supplied freely to the sheet rollers now, as the great drive is from the open hearth direct to the plate mills. In fact the rolling of ship plate is the great national business of commercial United States at the present moment. The United States Government is apparently satisfied with the manner in which the steel mills are acting, as it is announced now that there will be no further effort to take over the mills, as long as the entire output is handed to them for disposal. Canadian business for war orders will still be protected, according to the last announcements handed out from the conferences which have just concluded.

Makers of machine tools in Canada are finding it difficult to keep up with their orders. They have promised the delivery of equipment for new munitions shops on certain dates, basing their promises on the calculated capacity of the shops to which they had farmed out their work. In many cases there is a decided discrepancy between promised dates and the dates on which actual delivery will be made. There are bound to be delays in consequence in the delivery of shells on new orders.

The supply departments are busy. They have all the business they can handle. Deliveries are coming along in good shape, although some lines on which there is a continued run are rather short in stock.

## MONTREAL DEALERS FINDING IT A HARD MATTER TO FILL THE ORDERS

Special to CANADIAN MACHINERY.

MONTREAL, Que., June 11.—Industrial activity continues at a steady pace with developments enlarging in connection with shell contracts. Good progress is being made on several new shell plants and others are increasing their facilities for greater production relative to American contracts. Considerable difficulty has been experienced and is becoming more emphasized in obtaining machine tools as dealers report a marked scarcity of equipment suitable for shell making. Several local firms are actively engaged in constructing special tools for various sizes of American shells. The steel situation is still acute and promises to be more so in the near future. Metals are much firmer as a result of the better demand. Business generally is very steady with the greater volume confined to essential war requirements.

### Steel

Little relief has been given to the Canadian steel situation by the recent negotiations between the American producers and the War Industries Board. It is assumed that the restrictions upon the consumption of iron and steel will be further regulated, with the result that domestic requirements will only receive consideration after all essential demands are taken care of.

Ship construction is absorbing practically every ton of heavy plates, and although Canada has arranged for present and future requirements there are frequently times when delays are occasioned through the non-delivery of material. Some shell makers are also complaining of lack of steel which is being obtained from the States for American shell contracts. In the case of recent orders, however, it will be a few months before operations will develop to the point of production and manufacturers are hopeful of an improved situation.

One of the points that is not clearly defined in relation to essential needs is that of materials necessary to maintain plant equipment in the proper state of efficiency. Dealers here anticipate some anxiety over the higher cost in transportation on United States roads effective next month, and this circumstance may create a situation necessitating stronger Canadian prices.

### Metals

The situation is generally resuming a firmer tendency and the market is more stable since the announcement from Washington that copper prices would continue unchanged. This has helped to steady the other metals and the market has taken on a less nervous tone. Copper is unchanged on steady demand for government requirements. Tin is declining abroad but is stronger here. Spelter and lead are in better demand, and together with antimony are advancing.

**Copper.**—Opinion is becoming more general that the reaffirmed price of 23½ cents on copper is one that will tend to

stabilize this market to such an extent that at the expiration of the present term a further renewal will be effected. Little but government business is being accepted. Local dealers continue to ask 29 and 30 cents on a steady market.

**Tin.**—The Canadian situation is still acute but the easier market abroad has given a more optimistic tone and dealers are hopeful of relief in the early future, reporting better supplies in sight. Absence of immediate stocks however has forced the price up and dealers here are quoting $1.35 for spot metal.

### Machine Tools and Supplies

Machine tool activity continues to develop in considerable volume as a result of the steady placing of shell orders with Canadian firms, the supply of the necessary equipment is inadequate to the manufacturers' requirements, and dealers are experiencing considerable difficulty in acquiring the tools for their customers. As one dealer says, "we will soon have to advertise for machinery instead of machinery for sale." Steady progress is being made by those firms securing American shell contracts and machinery is being secured as rapidly as possible; several months must necessarily elapse, however, before production can be realized. Delivery of material and tools is frequently so uncertain that no definite prediction is possible as to actual time of starting on new contracts. No dealer and few producers will guarantee a specified date for receipt of materials, whether machine tools or supplies.

### Scrap

Activity in old materials is not pronounced and the interest of the trade does not appear to be of a character where developments may be anticipated. Dealers are not anxious to stock material that cannot be disposed of at an early date. Local transfers are good but heavy buying is receiving little attention. Dealers report a quiet week with business steady at unchanged prices. Old materials with lead as a basic metal are a little stronger.

## TONNAGE GROWING IN BRITISH YARDS

**Increase Noted of 85,741 Tons Over the Output Registered in April**

LONDON.—Merchant tonnage completed in United Kingdom yards and entered for service during May, 1918, was 197,274 gross tons, the highest figure for any month during the past year.

Official figures published to-day show that the completions for May marked an increase in tonnage over April, 1918, of 85,741 tons.

The next highest figures for any month in the past year were 161,674 gross tons in March, 1918.

The total completions for the twelve months ending May 31, 1918, were 1,406,838 gross tons. The corresponding figures for the year ending April 30th, 1918, were 1,270,337.

Commenting upon these figures, the controller-general of merchant shipbuilding says the satisfactory output for May reflects great credit on the whole industry, particularly on the firms engaged in fitting out vessels. The average time for fitting out has been reduced considerably. In one instance during May, a 5,000-ton steamer was completed for service within nineteen days of its launching.

## POINTS IN WEEK'S MARKETING NOTES

**U. S. iron and steel industry is running at only about 5 per cent. below the best it could do if all conditions were favorable.**

**Transportation facilities from Pittsburg are now referred to as being "adequate."**

**U. S. Government will not take over the steel mills of the republic, being satisfied to take the entire output.**

**New regulations will not interfere with the shipment of steel supplies to Canada for war purposes.**

**The hope that there would soon be a supply of steel for commercial purposes is vanishing into thin air as the war orders increase.**

**Canadian users cannot get coal orders filled in U. S. beyond former demands.**

**Machine tool dealers are behind in deliveries in many cases to firms having war business. They find trouble securing machine shop capacity to handle their orders.**

**The scrap metal market is just now at a standstill. Little trade is moving, as the material offering is not of a class called for in war work.**

**Orders for materials against which there has been no embargo are having to furnish minute details now before they are considered by the U. S. firms.**

**There has been an advance in the prices of sheets this week. Stocks are low and the demand for them is very keen.**

**Chain prices are up. Canadian mills are booked past capacity, and American mills are not getting any too great a supply of bars from the furnaces.**

## KEEPING THE SPIRIT OF EMBARGO LISTS

**Articles Not Listed Are Subjected to the Same Scrutiny as Others**

TORONTO.—Every day now sees the tightening up of business against the non-essential lines. There has been quite a time determining what is really means by "non-essential" lines. No man who has an organization around him and a factory behind him wants to come along and admit right off that his line is a non-essential. A customer came into a Toronto establishment this morning to fill out blanks for an order he had telephoned in previously. He was told not to lose any time in getting the forms returned, as every day means that it was that much harder to get his business through the War Board at Ottawa. Shipping has preference absolutely just now, and the turning of ingot production over almost entirely to the plate rollers is having a very marked effect in numerous ways.

Sheets show an advance again this week, and it may be that still higher figures will obtain for these.

Dealers in scrap metals are not doing a very great volume of business. The embargo against shipping to U. S. points still remains in force, and dealers claim they could do good business in lines that are not being seriously called for here at the present moment.

Machine tool dealers who have not the machine shop capacity to handle their own work are having a hard time securing the completion of war purpose machine tools. They have to "farm out" their stuff wherever the capacity can be found to handle it, and the result is that in not a few cases the dealers are behind on their promised deliveries to the firms who have taken on war business. These firms, in order, are behind in starting or the making of deliveries.

The demand is good for supplies of all kinds. Prices remain firm, and carbon and high steel goods are at the levels of last week.

### The War Grip

One feature has stood out in the steel market for some weeks now, and that was the manner in which the appetite of the war industries was increasing. The war business has elbowed its way up to the steel table and has practically crowded out the rest of the group. And chiefest in the war group is shipbuilding. That has the preference over all else, apparently, in the placing of orders. Munitions is also a favored line, and goods required for the production of electrical energy are also looked upon with favor. Outside of that it is a hard matter to classify. Only a week or so past a Canadian railroad placed an order for goods in the United States market. The order was of a nature that it could classify for the upkeep of the transportation system. But there has been all sorts of delay in the matter, and it is doubtful if it will be looked after for some time. The tendency in this narrowing of business is clearly apparent every day now. Dealers locally have been quite

[illegible] orders passed [illegible] Dept. This went out as far as [illegible] anything that is [illegible] war, and in very few instances do they have business returned to them that has been forwarded to headquarters.

[illegible] has been a rule that the embargo list was the guide by which to work, but the manner in which things are shaping now makes it certain that [illegible] the embargo list are being subjected to the same treatment. One Toronto firm placed an order in Boston for material against which there was no embargo, and they promptly received a request from the Boston firm asking for a Government order, and a description of the exact purpose to which the material was to be put.

### Prices Are Firmer

Prices of sheets are up slightly this week. There is a rush of orders and the stock on hand is small. When this condition comes to pass it is an easy guess that higher values are not far off. There is also the added fact that ingot production is going almost exclusively to the plate rollers and in consequence the sheet production is going to be smaller.

Higher prices are also given on chains, for either electric or fire weld. It is a hard matter to get shipments of American chain in here at present, as the United States Government has complete control of the plants, and the supply of bars going for the manufacture of chains is very limited. The Canadian [illegible] are also booked to and beyond capacity, so there does not appear to be very much relief in sight for some time to come.

### Scrap Market Quiet

There is very little business moving in the old metal market this week. There is a feeling almost of stagnation in the entire business. Supplies are not sought after by the buyers, as there are few buyers who want the class of material coming in. The American embargo is still on practically against all lines, although there are cases where shipments can be released under permit. Prices are not showing any changes, and the whole situation is dull at present.

### Delays in Delivery

Dealers in machine tools are in danger in some cases of being well behind in delivery dates that have been mentioned to firms putting in war plants. They have based their dates on promises made to them by machine shops scattered all over the country, and they are finding out now that the work is not going on at the rate they had expected, and as a result the whole delivery estimate is out of kilter. The dealer is the man in this case who has to stand the process of making continual explanations to his customer, although he can in turn hand it along to the man who is holding his sub-contract.

The supply business remains brisk locally. Houses have all the business they can conveniently handle.

# URGING FULL CO-OPERATION IN GIVING WAR ORDERS PREFERENCE

CANADIAN dealers who have reason to pass on business to firms in the U. S. are receiving daily circulars urging that there should be the fullest co-operation with the Government in its effort to turn the entire steel output of the country over to the War Board. The following is a sample, being sent by Joseph T. Ryerson & Son of Chicago:

Important Letter Refer to Buyer.

To All Customers:

Supplementing our general letter of December 8, 1917, there have been certain developments in the steel situation, during the past few days, which would be of vital importance to you. The shortage of steel in all lines has become much more acute than generally anticipated, due to the constantly increasing demands of the Government.

A representative of the Government has most emphatically stated to the steel manufacturers that the entire steel output of this country must from now on be devoted to the needs of the United States Government and its Allies in the prosecution of the war. This means that all business not intended for direct or indirect Government work must be subordinated to Government orders. We have joined with the steel industries in an agreement to carry out this policy as long as it may be necessary to assist in furthering the Government's war programme.

We will do our utmost to handle the legitimate requirements of our customers, as in the past. Orders for material required for war work and public necessities will have prompt and immediate consideration, but all others must be subordinated to them. In order to avoid delay we ask that you send with all orders and inquiries all the information possible as to ultimate use of the material. If needed for Government use, please advise Government order number and state, also, under which of the following classifications the work comes: Ships, Aircraft, Munitions, Military and Naval Supplies and Operations. If material is not for Government use, give us accurate and detailed information as to its ultimate use, as there are many most essential industries, necessary to the welfare of the country to-day, whose requirements should be given every consideration after the needs of the Government.

We earnestly ask your full co-operation in this matter, as it is an obligation resting on all of us to join in any movement which may help in winning the war. Yours very truly,

JOSEPH T. RYERSON & SON.

# U.S. WILL NOT TAKE OVER STEEL PLANTS

### But Entire Output Must Go Directly for the War Work of Government

Special to CANADIAN MACHINERY.

WASHINGTON, June 11.—Absolute Government control of the steel output of the United States has been accomplished this week through a voluntary agreement reached between the American Steel and Iron Institute and Bernard Baruch, chairman of the War Industries Board. The agreement is understood to have been an alternative to the taking over of the steel plants of the nation by the Government. Under the plan now arranged the steel plants will still remain private plants, privately operated, but the entire output will be at the direction of the Government.

Under the formal agreement drawn up all steel products must be devoted to those industries for which priority certificates have been issued. The War Industries Board will issue priority certificates with steel orders placed with the plants and each plant will be required to turn its entire production over to filling those orders accompanied with priority certificates. With these priority certificates filled the agreement then calls upon the steel manufacturer to devote his efforts to what is known as "preference" work. This includes all businesses which may be classed as war work and a list has been issued setting forth the relative importance of each industry to the conduct of the war. With "preference" orders filled the steel plants will then devote the remainder of their production to business which may be classified as non-essential. All non-essential shipments of steel must be subject to the approval of the War Industries Board and the Steel Director, however. The purpose of the agreement, as stated by Mr. Baruch, is to insure the steel needs of the United States and its Allies and then to equalize the distribution of the remainder of the steel product among those businesses which are not directly connected with the winning of the war.

### Regarding Canada

Shipment of steel to Canada will not be interfered with except in those cases where the steel is being used for non-essential purposes. Canadian manufacturers will receive the same consideration as manufacturers in the United States. The Canadian War Mission in the United States will work in conjunction with the War Industries Board and will advise on the issuing of priority certificates to those Canadian manufacturers doing war work and will also advise the War Industries Board as to the shipment of steel to preference industries and non-essentials.

For some weeks it has been planned to gain more complete control of the steel industry for the Government. It has been known that the proposition of the Government taking over the steel industry has been seriously considered by Chairman Baruch of the War Industries

Board. The present proposition, however, is understood to be that of the steel plant owners who desire to keep their plants under private control.

### Little Left Over

In conjunction with the issuance of the statement as to the agreement reached between the War Industries Board and the American Steel and Iron Institute there has arisen some difference of opinion among experts as to the available supply. The official view is, however, that the supply of steel is such that the demands of the United States and the Allies will not leave a very large supply of steel for use in non-essential industries.

In order that there may be a checking up each manufacturer of steel will be required to file a weekly statement of his shipments with the War Industries Board.

### Coal Orders

The coal problem is again cropping out in the United States. The past week has been designated as "coal week" and efforts have been made to secure orders for all coal necessary during the coming winter. The success of the week is still doubtful, however. The Fuel Administration during the week has issued a statement as to the estimated demands for bituminous coal during the coming season and this estimate shows that there will be an increased demand for 79,866,000 tons. This will mean that there must be an increase in production of 14.4 per cent. Thus far this season the increase in production has not consistently approached this figure. The Fuel Administration has issued orders for the restriction and conservation of bituminous coal and it has decreed that there shall be no increased exports of bituminous coal. This will mean that Canadian manufacturers who have received their bituminous coal from the United States will be forced to keep to the same amount which they have used in previous years. A general reduction of bituminous coal rates to North-west and Great Lakes points has been ordered by the Fuel Administration, however, which will work to the advantage of Canadian purchasers of American coal. This reduction of price is estimated to offset the increased freight rates and to maintain the stable price on bituminous coal. Because of the possibility of a shortage in anthracite coal, Canadian users have been ordered to cut their demands. The shipments of anthracite coal to Canada last year have been ordered reduced 6.59 per cent. this year.

The month of May was the record month for shipbuilding in the United States. During that month 44 steel and wooden vessels were delivered to the United States Shipping Board. This meant an aggregate tonnage of 263,571 tons. The best previous record was for the month of March of the present year, when 21 steel and wooden vessels, with an aggregate tonnage of 172,611, were delivered. The Shipping Board has announced that more than a million tons of steel vessels have now been delivered that body. So well pleased with the production of ships now is Charles Schwab, director of shipbuilding, that he has proposed a competition in ship production between the Hog Island yard at Philadelphia and any three of the English yards.

The Bureau of Mines has just issued a statement showing that the production of smelter copper in the United States during the past year has decreased 2.18 per cent.

## FIGURES THAT MAKE THE READERS DIZZY

### Enormous Amounts Still Being Spent on War Equipment by U. S. Government

Special to CANADIAN MACHINERY.

NEW YORK, June 11.—All of the steel produced in the United States is now under complete control of the United States Government, in accordance with an agreement entered into between a committee of the Iron and Steel Institute and a committee representing the War Industries Board. Although the Government does not assume direct control of the manufacturing plants, it does direct the distribution of all products, and even has a voice in the management of production, as the Director of Steel Supply, in conjunction with a committee of the Iron & Steel Institute, is now making a study of war requirements with a view to stimulating production to the utmost. If any surplus of rolled steel exists after full requirements of the United States and its Allies have been met it will be distributed in accordance with a preferential list of industries engaged indirectly in the manufacture of war munitions, but no shipments can be made until approved in writing by the Director of Steel Supply.

Expansion of shipbuilding facilities continues to make a heavy draft upon the resources of all manufacturers of machinery. A new plant is to be built adjoining the present yards of the New York Shipbuilding Corporation, to cost $10,000,000. The funds will be furnished by the United States Government. McClintic Marshall Construction Co. will furnish the 20,000 tons of fabricated steel required for the various buildings. Several million dollars will be spent for cranes, conveying machinery and shop equipment.

Other shipbuilders are also in the market for machine tools. The Carolina Shipbuilding Co. has closed several important contracts for its Wilmington, N. Carolina, yards, but has not yet let the contract for the fabrication of 30,000 tons of steel plates and shapes for the twelve boats it will build for the Emergency Fleet Corporation. The officers of this company will be transferred from New York to Wilmington July 1st. The Newport News Shipbuilding & Drydock Co., in addition to improvements to its shipbuilding plant at Newport News, Va., will construct a plant at Richmond, Va., for the manufacture of marine boilers, turbines and auxiliary ship propelling equipment. A large list of cranes and tools for equipment of these shops has already been sent out. The General Electric Co., as well as the Westinghouse Electric & Manufacturing Co., is preparing to increase the output of marine turbines, for which additional machinery is needed. The Lester, Pa., plant of the Westinghouse Co. will be increased 40 per cent. The American Steel & Forge Corporation, Philadelphia, is expected to build a new plant for making crank shafts and other large ship forgings.

Several large shipbuilders on the Pacific coast are in the market for machinery and tools of various kinds, which will cost approximately $5,000,000. The Skinner & Eddy Corporation, Seattle, Wash., is building a dry dock and ship repair plant, to cost about $2,000,000. The Hewitt Drydock & Shipbuilding Co., Tacoma, Wash., will construct 20 shipways for the building of steel ships, and the North-west Steel Co., Portland, Ore., is expanding its plant on the Willamette River, where four additional ways will be built.

Several large contracts for guns and shells recently placed by the Ordnance Bureau of the War Department are revealed in the demand for machine tools. The New Home Sewing Machine Co. has a contract for small shells, and a manufacturer in New York State, who has received an order for 6-inch guns and 6-inch shells, will build a new plant requiring large tools. The Peninsular Shell Co., Saginaw, Mich., has been given an order for 1,000,000 trench mortar shells. American mills have received heavy specifications for shell steel to be shipped to Canada. A gunmaker on the lakes is calling for 30,000 tons of steel ingots, and a Cleveland manufacturer of munitions is seeking 10,500 tons of electric steel blooms.

## MAY REOPEN THE ROSS RIFLE PLANT

### Negotiations Are On Now Looking to That End—Splendid Works There

Special to CANADIAN MACHINERY

MONTREAL, June 11.—It is reported that negotiations are under way for the reopening of the factory of the Ross Rifle Co., at Quebec. Interested parties are in touch with the Canadian government for the utilization of this plant.

On a recent visit to the City of Quebec the Minister of Marine inspected the works and was surprised that such a splendid plant with its modern equipment should be practically idle at this time, and he intimated that the near future would see the place in active operation again.

**May Raise Rates.** The Railway Board has granted the application of the Brantford & Hamilton Electric Railway Company [illegible] the same increases in freight rates as have been authorized in the case of steam railways [illegible] the railway had no agreements with municipalities so holding down the limits of freight rates as in any way to conflict with the application.

# WITHIN FIVE PER CENT. OF CAPACITY

## Good Showing of American Factories is Still Being Well Maintained

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., June 11.—A per[illegible] for the distribution of [illegible] was [illegible] to [illegible] the [illegible] of the War Industries Board of June 6. The arrangement differs in form, but not materially [illegible] that has been in vogue since the producers took their pledge of 100 per cent. efficiency for war work as a result of the meeting [illegible] Director of Steel Supplies and representatives of the industry.

There are three classes of pig iron and steel products. Material for war, material for more essential industries, and material for less essential industries. The last named term is a euphemism, used in place of "nonessential," because it is admitted that in the last analysis there is no material that would not in some slight degree help in winning the war, at least according to the arguments of those who desire the material.

The first class has been regulated for months past by the issuance of priority certificates by the priorities division of the War Industries Board. The second class has all along been given more or less special recognition by the manufacturers, of their own volition, and lately some industries using material of this class have been given special recognition by the mills as a result of the direct instructions by the War Industries Board.

The decision reached June 6 followed the temporary arrangement that existed under the 100 per cent. pledge (which of course remains in effect as to its general tenor) whereby the producers were distributing material to the more essential industries according to their own judgment, but it greatly amplifies the list of more essential industries. The decision also settles the somewhat vexed question as to the machinery by which material should be distributed to the more essential industries. There was a possibility at one time that the War Industries Board would distribute this material by a system of priority certificates. These, as in the case of war material, would refer to specific lots of material. If it did this it would be regulating the distribution of all pig iron and steel products, ton by ton, except such material as might be left over and could be shipped to anyone irrespective of the use to which it would be put. This possibility is now removed.

The arrangement now adopted is this, that all war material is to be controlled by priority certificates as formerly, and that material for the more essential industries is to be distributed by the producers themselves, but in accordance with precise regulations of the Board, decreeing the "purposes" which are to be given preferential treatment. If there is any material left over, it can go where the producers prefer to ship it.

While the resolution, which is quite lengthy, is entirely explicit in general form, it leaves one thing with respect to which there may be much divergence in practice from time to time. That one point is this, that "priority certificates" are dismissed with a few words, while the "schedule of purposes entitled to preference treatment" is quite lengthy. Thus there is no pronouncement as to the items for which priority certificates will be issued. Railroad requirements are named in the "schedule of purposes" and yet priority certificates can of course be issued for specific lots of material—for instance, for a given lot of locomotive cars, or a given lot of rails. In general, however, the priority certificates cover war material ordered directly or indirectly by the United States Government for itself and its Allies.

The "schedule of purposes," which take preference after priority certificates are filled, includes shipbuilding, aircraft, fuel, food and collateral industries, clothing, transportation and public utilities.

### Exports

It is, perhaps, not altogether clear whether the "schedule of purposes" contemplates the supplying of material for export as well as for use in the United States. This will probably be referred to in more detail in subsequent regulations. Steel for Canadian shell factories of course, would be the subject of a priority certificate. Steel for an agricultural implement is included in the "schedule of purposes," and as the agricultural implement makers have been put under license, the specific regulations laid down for them will doubtless cover the matter of what products they may export, and in the case of that industry the steel mills may have nothing to decide. Containers of food are included in the schedule, but the exportation of tin plate for making food containers may be controlled simply as formerly by export permits issued by the War Trade Board.

### How Industries Will Fare

In the past few weeks there has been a distribution of pig iron and steel products much the same as that now provided by the new regulations, which are, however, more explicit and comprehensive. There has been opportunity therefore to observe in a measure how the system will work. Many consumers are of course incommoded because they have been denied steel entirely, but the total tonnage involved is not large by any means. If the present system had been imposed in 1913, or even in 1916, it would have created the most profound changes, but since the United States entered the war there has been a great diminution in the steel used for certain purposes, as, for instance, in building, while the great majority of manufacturing consumers have changed their products so that they are making war material instead of "less essential" things, and thus the dislocation is not so great after all. When building disappears and the railroads are given preferential treatment, it can be seen that would-be buyers who are denied material do not represent any very large percentage of the total output.

### Production

Production of pig iron in May was at the rate of about 40,900,000 gross tons a year, or somewhat less than was estimated in many quarters, estimates of the average rate running up to 42,000,000 tons. However, the May rate was the greatest on record, barring October, 1916. On the basis of pig iron, it may be estimated that the output of steel ingots was at the rate of at least 43,000,000 tons a year. Under the new order of things, brought about by the 100 per cent. pledge for war efficiency, the production of ingots is stimulated while the production of finished rolled products is curtailed, relative to ingots. This comes about by the mills melting up as scrap such material as shell discard steel and sheet bar crop ends, whereby this material is weighed over again in ingot form whereas under former practice the material was rolled into merchantable form, shell discard steel making light rails, concrete reinforcing bars, bedstead angles, etc., while sheet bar crops were piled and rolled into sheets suitable for certain purposes, not particularly exacting.

Manufacturing conditions in the iron and steel industry as a whole are fairly satisfactory, and somewhat better than was expected last winter could be the case at this time. Transportation facilities are practically adequate. Coke supplies to blast furnaces are a trifle scant, but the large amount of new by-product coking capacity about to come in should entirely right that situation. Labor supply is not altogether adequate and is probably restricting production by a very few per cent. The iron and steel industry, however, is running at only about 5 per cent. below the best it could do were all conditions altogether favorable.

---

**Anodes are Scarce.**—Trades using Cobalt anodes are finding them a little scarce at present, and the price on a higher level than for some time past. Cobalt metal is quoted now at around $2.50 to $3.50 per pound. This means, of course, that on fairly large orders manufacturers would be prepared to quote a price of $2.50 ,while a deall where a smaller amount was involved would be based on the $3.50 scale. Cobalt anodes are now worth from 25c to 50c per pound in excess of these prices, according to the shape in which they may be required by the customer. The difference between the cost of the metal and the cost of the anodes would be absorbed in the process of manufacture.

---

PLATINUM deposits have been discovered in Germany, according to a report from Hamburg which states that numerous veins of blue quartzite containing platinum in quantities to repay exploitation have been located in a stone quarry at Ober-Rosbach (Taunus).

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

### TENDERS FOR POWER PLANT

[illegible] Sydney, New South Wales, has in operation an electricity supply system. By means of this system electricity is supplied to more than 25,000 separate premises where it is used for lighting and for the driving of machinery in factories of all kinds, heating, cooking, etc. Among other establishments supplied with electricity are the Royal Naval Repair Dockyard, the board dealing with the water and sewerage of the metropolitan area, many factories principally employed at present in making material to the order of the Defence Department of the Commonwealth of Australia for the use of the naval and military forces. In addition to the above uses the council's supply of electricity provides artificial lighting for some hundreds of miles of streets and roads.

"It has been suggested that the Canadian manufacturers are just now in a much better position to undertake contracts for the supply of heavy engineering plant than British manufacturers.

"Following is a rough description of the principal items of power-house plant which the city council would require if it is decided to proceed immediately with the extension of the power-house:

"1. Boiler-house plant, consisting of water tube boilers of the Stirling or Babcock and Wilcox type, complete with economizer super-heaters and automatic stokers, forced and induced draft fans, etc., each boiler to evaporate up to about 50,000 pounds (actual) of water per hour at a steam pressure of, say, 225 pounds to the square inch; the number of boilers to be dependent on the size of turbo alternator, about one boiler for each 2,000 kilowatts in output of turbo alternator (see below).

"2. Electric generating plant. One steam turbo alternator, three-phase preferably, of about 12,000 kilowatt capacity but not less than 6,000; the turbines to be suitable for a steam pressure of about 200 pounds per square inch and a steam temperature of 600° Fahr., the alternator periodicity to be 50 complete cycles per second, and voltage to be 5,000 to 5,300. The set to be complete with condenser, circulating pump, air pump, etc.

"3. Cranes. One electric overhead travelling crane for a working load of 80 tons with a span of about 45 feet.

"4. Steam turbine-driven feed pumps, say, two, each sufficient to feed the boilers referred to above.

"5. Steel pipe work to couple up the boilers referred to above to the turbine referred to above.

"6. Switchgear. One remote electrically controlled switch to control the current from the alternator described above.

"7. Copper boiler feed pipes with brass flanges."

The city council of Sydney would be prepared to order this plant from Canada if assured that the work could be proceeded with immediately and quickly completed.

Firms in a position to tender should communicate with the Commercial Intelligence Branch, Department of Trade and Commerce, Ottawa, referring to file No. 17986.

### BRITISH STEEL FOR SHELLS

THE British investigation of an acid open-hearth heat for making high explosive shells, reviewed in a recent issue of the "Iron Age," presents some interesting facts. It demonstrates the high degree of uniformity obtainable from the practice of casting the ingot large end up with a hot top. Not only is the percentage of discard largely reduced, but defects from segregation and pipe are at a minimum. It would be interesting to know to what extent this is the practice in England. Without doubt some such procedure is desirable to meet the rigid specifications. It is admitted that in the United States early in the war some steel-makers had great difficulty in satisfying foreign inspectors with steel cast in ingots with the small end up with no hot top or even with one. To what extent this American practice has been altered to meet new war conditions is not generally known, but in some cases decided changes are believed to have been necessary. It is certain, however, that the British method referred to is superior.

It is also interesting to note that in the heat under discussion additions of manganese and silicon were made in the bath and not in the ladle, and also that no ore was added after the percentage of carbon reached 0.70 per cent. Both of these points are vitally important in the production of the best steel, but their value is not always recognized or lived up to in tonnage production.

The manganese content of the slag for the heat reported is illustrative not only of the loss of manganese, but also of the importance of the slag as a by-product. It is hoped that steel making will some day reach the stage where so large a loss can be eliminated. It is claimed that this has been done in the electric furnace. It is also not at all impossible that a way may yet be worked out for reclaiming the manganese, silicon and iron content in acid slags in the shape of a silico-manganese alloy. Important work on this is now being done in this country.

### GROWTH OF STEEL AND IRON INDUSTRY IN NEW SOUTH WALES

B. MILLIN, Canadian commercial agent for New South Wales, writes from Sydney as follows in regard to the growth of the steel and iron industry in that State:

"A second blast furnace is now in operation at the Broken Hill Proprietary Co.'s works at Newcastle, New South Wales, and the equipment for producing plates for shipbuilding has just been completed. The rolling of these plates will supply a long-felt want in Australia, as at present they are almost unobtainable. A rod mill has also been erected, and this plant will roll wire rods, from which fencing wires and other wires are to be drawn. The total number of employees now employed at the works is 3,000, and this number will be shortly increased.

"As the steel works progresses it is becoming more and more apparent that subsidiary industries will be attracted to the district, because of an assured steel and iron supply, as well as cheap coal and adequate railway and shipping facilities.

"It has been decided to establish extensive works for the purpose of manufacturing galvanized iron at an initial expenditure of about £150,000.

"Another industry that is likely to be established as soon as the necessary machinery comes to hand is a steel products works, and a large nail manufacturing company also contemplates establishing works in the near future."

### Production of Platinum in New South Wales

The New South Wales Mines Department reports the discovery of an important deposit of platinum in this State, and it is stated to be the most important alluvial find for some years.

Platinum in small quantities occurs in several districts, but platinum mining, in comparison with other branches of mining, is unimportant. The productive deposits are, however, only of comparatively recent discovery. The quantity of platinum produced to the end of last year was 13,676 ounces, valued at £34,274.

In the recent discovery the metal has been found associated with gold in washdirt and occurs in coarse, shotty grains.

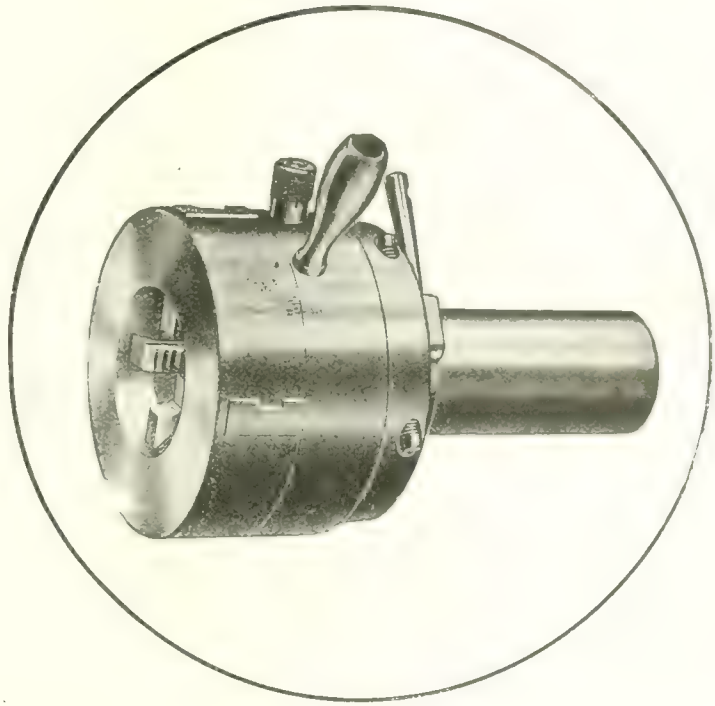
## NO END TO WAY OF RIVET DRIVERS

### Over 12,000 Rivets Were Driven in a Nine-Hour Day

To drive in 12,209 ⅞-in. rivets in nine hours into a standard ship was the feat accomplished at the yards of Workman & Clark at Belfast by John Omir, who last week beat the hour record for the United Kingdom. In his work Omir drove in more than a thousand rivets every hour, and on two occasions passed the 1,400 mark. In his best minute he drove 26 rivets. Omir used about two and one-half tons of metal.

**New Incorporations.** — Incorporation has been granted to the following joint stock companies: Carter, Wood Shipping Company, Limited, Montreal, capital $40,000; Midland Iron and Steel Company, Limited, Midland, Ont., capital $1,000,000; Canadian Northern Rolling Stock, Limited, Toronto, capital $100,000; British Columbia Coal & Land Company, Limited, Hamilton, Ont., capital $750,000; Bird & Son, Limited, Hamilton, Ont., capital $750,000; Halifax Shipyards, Limited, Montreal, capital $6,000,000; Clyde Engineering Company, Limited, Montreal, capital $100,000.

# GEOMETRIC



**"Around the Geometric Die Head we draw a circle and claim that no other can touch it for quality and quantity production."**

*That is the claim of the Manufacturer.*

*This is the claim of the User:*

> "We purchased four sets 9 16 -18 chasers from you four months ago, and are pleased to state that the first set is still in use and doing perfect work, although it has been used almost daily since purchased, and threading better than a thousand pieces per day."

From 1,000 to 4,000 threaded pieces, according to work conditions, is the reputation of Geometric Die Heads. Unless you know what GEOMETRIC experience is, you have yet to learn what can be accomplished in the production of screw threads.

*We are ready to help you. Ask us about it.*

## THE GEOMETRIC TOOL COMPANY

### ALUMINUM GOODS FOR BRAZIL

There is in Brazil a market for as much aluminum as can be supplied, which material has been scarce for some months past having been completely exhausted. This dearth of supplies is entirely due to the cessation of shipments of German consignments through neutral ports, which continued for some time after the outbreak of war. Although some small shipments of aluminum manufactures were sent to South America from the United Kingdom, three-fifths of the imports of articles of this class came formerly from Germany and Austria-Hungary. The demand among the Brazilians—and, incidentally, in all other South and Central American countries—for cheap cooking utensils. German goods, when obtainable, have been invoiced at very low figures, against which it has been difficult for either British or American manufacturers to compete. Small saucepans and frying pans sold at 3½d. to 7½d. each, and a larger size at 1s. 1½d. Eggcups and strainers are retailed at between 1½d. and 2½d. each, spirit-lamps at 7½d., timbales, cups, and stoppers at prices from 4d. to 9½d. each. It should be worth while for British manufacturers of such aluminum articles to send out a full range of samples, making the wholesale prices as low as possible, and affording a reasonable amount of credit to the larger and safer importers. These, in making distribution for up-country sales, have to allow credit between six and twelve months. Even the retailers seldom sell for actual cash, credit being the rule in all parts of the country. The value of the German trade in these goods with Brazil amounted in normal times to over £16,500; Argentina took shipments worth £6,400, Chile £8,100, and Mexico £3,100. The trade of the United Kingdom was almost negligible excepting with Brazil. It is worthy of attention that the United Kingdom itself took goods from Germany—including those of aluminum crude, wrought and spun, and aluminum wire—worth over £25,800, while the United States, where there are manufactures of such a nature, purchased from Germany to the value of £53,000. Manufacturers may be interested to know the principal reason that the Germans can sell their aluminum hardware. The German articles are "spun" instead of being, as is the case with British goods, "cast." It would therefore be advisable to attempt some method which would allow of their supplying "spun" articles at a low price. It is apparently possible, as the Germans have succeeded in doing it. In addition, South American purchasers prefer the dull, silvery appearance of the German-made aluminum articles to the polished, tin-like appearance of the British-made goods. Finally, the Teutons have been in the habit of allowing their South American customers a discount of 45 per cent. upon all aluminum ware, and 2½ per cent. discount on aluminum wire. The more saleable of the aluminum hardware articles exported to Brazil include meat-dishes, pudding-bowls, colanders, pie-dishes, forks, spoons, stewpans, milk-boilers, kettles, saucepans (the latter in all sizes and with or without lids), spirit stoves, etc.

### TRADE INQUIRIES

THE following trade inquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained from the inquiries branch of the department.

242. **Automobiles and mining Supplies.**—A firm in Bulawayo, Rhodesia, South Africa, which has mail, transport and cartage contracts with the Government of Rhodesia and with a number of mines, wishes to correspond with Canadian manufacturers in various lines, especially automobiles and mining supplies, with a view to representing them in Rhodesia either immediately or after the war.

243. **Electric lamps, parts and acessories.**—A firm of London importers wish to get in touch with Canadian wholesale houses who can export electric lamps, parts and accessories.

249. **Hoop-iron, etc.**—A manufacturer of barrels engaged also in the fish-packing trade in Newfoundland asks for the names of Canadian exporters of hoop-iron, 1¾ inch to 2 inches wide, 16 gauge, flanged and cut in lengths of 62 inches. Also coopers' rivets.

259. **Electric and pneumatic machine tools.**—Agent at Naples seeks agencies for electric and pneumatic machine tools and instruments, bolting, etc.

267. **Engineering articles, leather belting, etc.**—Turin commission agent would handle engineering articles, leather belting, files, mineral oils, etc.

268. **Mild steel for shipbuilding, emery cloth and wheels.**—Commission agent at Genoa wishes to represent British firms: Mild steel for shipbuilding, emery cloths and wheels, engineering sundries, cutlery, tools, belting, glass paper. (N.B., fluent English.)

275. **Electric apparatus.**—Turin merchant is interested in electric apparatus.

280. **Beaten metalware.**—Turin agent would handle beaten metalware, engineering articles, machinery for metal-working.

281. **Industrial sundries.**—Merchant at Turin would import on own account or commission industrial sundries, iron tubing, articles for boilers.

297. **Mining supplies.**—A Johannesburg commission house with a long-established connection in mining territories is prepared to take up the Canadian representation of mining supplies of all kinds.

425. **Machinery and engineering specialties.**—A Durban firm specializing in machinery and engineering specialties requests catalogues and latest information from Canadian exporters of general machinery, mining machinery, pumps, concrete silo pattern, agricultural machinery, shovels, wheelbarrows, and other lines suitable for this trade.

426. **Rubber goods.**—A Durban firm of merchants desires samples when possible, catalogues and price lists on all classes of rubber goods. They are prepared to purchase for Natal or act as agents for the Union of South Africa.

427. **Iron and steel products, tools, chemicals, leather, paper, agricultural implements, etc.**—A Durban firm of merchants and commission agents requests correspondence from Canadian manufacturers of coal mining material, rails, wheelbarrows, steel plates, shovels, coal mining tools, chemicals (caustic soda, bicarbonate of soda, phosphoric acid, arsenite of soda), glucose, lubricating oils, leather belting, agricultural machinery and implements. Will purchase outright in many of these lines or prepared to act as agents.

430. **Catalogues.**—A Port Elizabeth wholesale firm requests catalogues and price lists from Canadian manufacturers of hardware of all kinds, tools of all kinds, lanterns, spades and shovels, picaxes, enamelware, household utensils, paints and varnishes, brushware, fencing and baling wire, wire netting handles.

## BOOK REVIEWS

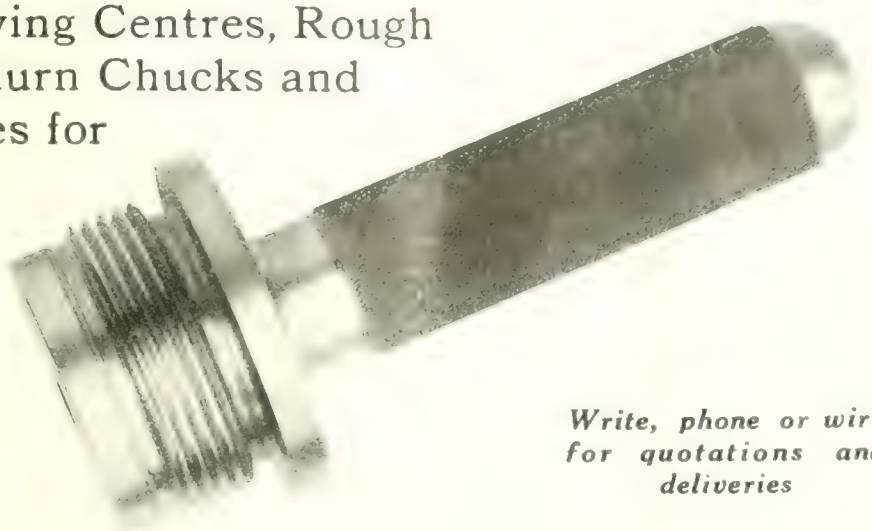
**Craft of the Hammersmith** is the title of an illustrated booklet issued by the Canada Foundries & Forgings, Ltd., of Welland, Ont. The booklet illustrates by means of excellent photographic reproductions the various phases of the operations performed in the production of marine forgings at the Canada Forge plant and also views of a few typical forgings made by the company. The booklet is gotten up in an artistic manner and shows the marked development which the company has made, in this particular line, during recent years.

**Drilling Machines.**—The Henry & Wright Mfg. Co., Hartford, Conn., have issued an attractive catalogue illustrating and describing an interesting line of single and multispindle drilling machines. A list of improvements made in the design of these machines is given, followed by a very useful chart of speeds and feeds for drilling, covering both carbon and high speed drills. The various types of drilling machines are illustrated according to their classification and are accompanied by specifications giving the principal dimensions, weights, etc.

**The Collapse of Short Thin Tubes.**—Professor A. P. Carman of the Department of Physics, University of Illinois, has completed a series of experiments on the Collapse of Short Thin Tubes. The purpose of these tests was to find an equation by the application of which the pressure required to collapse a tube can be calculated when the dimensions of the tube and the elastic properties of the material are known. The results of tests of longer tubes were published by the Engineering Experiment Station in 1905 and the present report contains a brief summary of these earlier tests. Seamless steel, seamless brass, aluminum, glass, and rubber tubes mere used in the new tests. Bulletin 99 of the Engineering Experiment Station contains the results of these tests. Copies may be obtained gratis by addressing the Engineering Experiment Station, Urbana, Ill.

# Screw Gauges for 155 mm. U.S. Shell

Also make Revolving Centres, Rough turn Chucks, Re-turn Chucks and Recessing Fixtures for this size shell.



WE have equipped two plants in the United States with these tools.

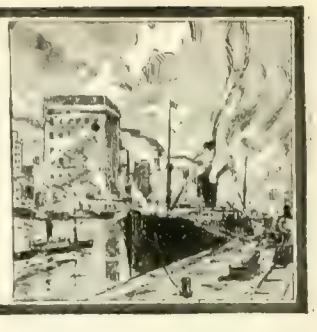
# INDUSTRIAL NEWS

## NEW SHOPS, TENDERS AND CONTRACTS' PERSONAL AND TRADE NOTES



## CONTRACTS

**Sudbury.**—Fraser & Chalmers of Canada, Limited, Montreal, Que., have been awarded a contract by the Corporation of the Town of Sudbury, Ontario, for the supply of a 1,200 gallon per minute Lea-Courtenay turbine pump for direct connection to a 175 h.p. Canadian Westinghouse motor.

## ENGINEERING

**Detroit.**—Henry Ford has this to say of the much-discussed Liberty motor; "It is a wonderful creation. It is undeniably the finest mechanism of the kind the world has ever seen. It represents about the maximum of power possibilities in aeroplane motors, inasmuch as it develops about two horsepower for each pound of weight. The men who have worked out this extraordinary motor deserve the thanks and heartfelt appreciation of the nation."

**Chicago.**—A portable track welding outfit weighing less than 200 pounds which takes its power from trolley wires has been invented for small street railways that do not require elaborate equipment.

## MARINE

**Belfast.**—To drive 12,209 seven-eighth inch rivets in nine hours into a standard ship was the feat accomplished at the yards of Workman & Clark here by John Omir, who used about two and one-half tons of metal.

**Sarnia.**—The ferry, James Beard, was raised by the lighter Manistique after Diver John Mara had completed the preliminary work. This afternoon the boat was towed across the St. Clair by the ferry Grace Dormer into the Black River, and will be repaired as quickly as possible.

**Montreal.**—The 7,000-ton cargo ship War Earl was launched from the yard of the Canadian Vickers, Limited, on Saturday morning. The vessel has a length of 380 feet and a breadth of 49 feet. Five minutes after the War Earl was launched another keel was laid down, and this ship will be completed about the first of October.

**Niagara Falls.**—It is interesting to note that in the colossal enterprise in the building of the Chippawa-Queenston Hydro-Electric Power Canal, involving the expenditure of millions of dollars, the employment of a thousand men and the most modern and efficient machinery in the world, during the twelve months the great public work has been in operation, only two men have been killed.

**Quebec.**—The new Canadian Northern car ferry Canora, which has been built here by the Davie Shipbuilding & Repairs Co., was launched at the company's dry-dock at Lauzon. The new steamer, which will ply between Victoria, B.C., Patricia Bay and Port Mann, is 308 feet long, 52 feet beam, has a capacity of 20 loaded cars and a speed of 14 knots an hour. The Canora is a coal burner and cost between $400,000 and $500,000.

**Sarnia.** — The passenger steamer Noronic was moved from her winter quarters in Sarnia Bay to the Northern Navigation dock, where preparations for the opening of the passenger season will be completed. The other two boats, Hamonic and Huronic, have been in service since the opening of the season of navigation, and have done much to move the freight of the country both ways. The steamer Waubic, which operates through Georgian Bay, is now being fitted out for the season.

**St. Catharines.**—A mistake in signals between the captain and engineer of the steamer Linden, owned by the Ontario Paper Company, carried out three gates of lock 4, Welland Canal, on Thursday, and tied up traffic for a couple of days. As she was entering lock 4 the captain attempted to signal for a check down, but instead the steamer crashed into the two head gates and tore them from their fastenings, letting loose the waters of the level above into the empty lock. The steamer was thrown into the level below and one of the lower gates was torn away.

**Collingwood.** — Between seventy-five and one hundred employees of the Collingwood Shipbuilding Company who went down to work on Tuesday morning were informed that as they had taken the King's birthday as a holiday they could take Tuesday without pay. At the plant it was stated that a written agreement had been drawn up between the company and the men in which it was agreed that Victoria Day was to be observed as a holiday, while work was to be done on the Kin's birthday. Instead of this many of the men took both days as holidays, and as a result much inconvenience resulted to the company.

**Halifax.**—A cable received by M. O. Crowell of Crowell Bros., Limited, vice-president of the Larder Bros. Wrecking Company, Halifax, announces that the Larder Bros. Company have been awarded the sum of $86,480 by the arbitration court in England as their remuneration for salvage services performed to the steamer Arachne in 1916. The steamer Arachne went ashore on the Island of Langlade or Little Miquelon in June, 1916. Larder Bros. were employed to salve her and were successful in floating the ship and having temporary repairs made in St. Pierre and afterwards taking her to Quebec, where she was repaired in dry dock.

**Sault Ste. Marie, Ont.**—Freight traffic carried through American and Canadian canals in May amounted to 11,404,045 short tons, the total having been exceeded for the month of May only in 1916, when freight traffic was 12,293,476 short tons, including much heavier shipments of wheat and grain than were handled last month. The movement of iron ore, 8,792,162 tons, was greater than in May, 1916. Soft coal shipments exceeded May, 1917, but fell short of those in 1916, while the movement of anthracite was lighter than in May of either of the two previous years. A feature of the statistical report is the small amount of manufactured iron and steel and of general merchandise included in westbound shipments, this curtailment being traceable to the war.

**Port Stanley.**—A fall of two feet in the level of Lake Erie has been reported by residents of Port Stanley. The fall is sufficient to cause much trouble in the unloading of boats, as it brings the decks a considerable distance below the docks. This makes a steep grade up which the merchandise must be taken. The Bessemer experienced this difficulty at Port Stanley and great care had to be exercised in unloading the coal cars. There is a variation in the height of the water level in Lake Erie every year, but the water line this season is reported to be much lower than it has been for years. No satisfactory explanation of the cause has been advanced. There is a periodic rise and fall in all the Great Lakes, but according to past experiences the water should be still rising and should not commence to recede until next year. If the phenomenon was temporary, a strong wind might have been the cause, but in this event it is not likely that the water would remain at the low level for more than a day. Rainfall in the north coun-

try affects the lakes to a great extent, and if the fall there has been much less than normal it may account for the lower level in Lake Erie.

## MUNICIPAL

**Halifax.**—A meeting of the city council passed a resolution granting tax exemption to the Norcross Syndicate for the construction of steel shipyards at Halifax. The initial expenditure, it was explained, will be between three and four million dollars, and the industry, when running to full capacity, should give employment to between three and four thousand persons.

**Renfrew.**—The town council, through the waterworks' committee, has decided to purchase a twin horizontal enclosed turbine waterwheel, and a 12-inch two-stage pump. It is practically a duplicate of the present outfit. Some idea of the way prices are increasing can be gained from the fact that the present price quoted is $1,244 over the quotation of October 23, 1917, and $1,640 over that of July, 1917.

**London.**—As a result of a secret joint session of the Board of Control and the Locomotive Railway Commission, of which Sir Adam Beck is chairman, a recommendation that London purchase the section of the London and Lake Erie Traction Co., between this city and St. Thomas, at a price of $250,000, providing the other municipalities concerned grant a bonus of $50,000 to make up a total of $300,000, will be considered by the City Council.

**Winnipeg.**—One result of the decision to make the West dependent on Alberta for a coal supply this winter has been a move for an investigation into the price that is to be paid. One of the Winnipeg papers has gone into the matter at some length, pointing out that the price of the coal at the mines is from four to four and a half dollars. The same article delivered to the consumer is paid for at the rate of $12.50 per ton, and it is held that the spread is too great. The Winnipeg Board of Control are also taking action in regard to the same matter.

**Montreal.**—Sir Herbert S. Holt, presiding at the annual meeting of Montreal Light, Heat and Power Company, Consolidated, stated that while the new La Salle gas plant had been considered sufficient for five years' growth, enlargement would be necessary to meet the growing demand. The directors were not inclined to go ahead with extensions just now, because of the high cost of machinery, etc., but an extension in this case was virtually forced on the company by conditions. Sir Herbert referred to the rates for gas and electricity in Montreal being the lowest in America, and reaffirmed the company's intention to make no change unless further increases in cost of operation, taxes, etc., compelled such action.

**Dundas.**—Tenders were opened on May 14 for a mechanical filter plant. The

# Manager Wanted $50,000 Salary

A STRONG man—a tactful man—a man who will create sympathy and respect and support for the greatest factor in the upbuilding of Canada. A man who will curb the few selfish, the grafters, and the offensive combines which exact exorbitant profits, and bring the 95 per cent. decent Canadian manufacturers into disrepute, subjecting them to unfair and confiscatory legislation. A man who will work in unity with the press of the country, with the farmers, trade unions, and various journals, and finally and most important of all—a man who will organize Canadian industry for the greatest possible output of the best quality goods. Such a man can do more than any other to make Canada permanently prosperous. Such a man, says THE FINANCIAL POST of June 1st, should be secured as Manager of the Canadian Manufacturers' Association. You will find the article containing this and other powerfully constructive thoughts on page 1 of THE POST now on sale.

**Know Canadian Affairs**

News of Canadian Securities forms an important feature of THE FINANCIAL POST every week. In addition to the fifteen columns of the June 1st issue devoted to this department the following up-to-the-minute business articles appear:

## Hawkridge Brothers Company

303 Congress St., BOSTON, MASS. U. S. A.

THE IRON WORKS LIMITED

Successors to
Owen Sound Iron Works
Owen Sound, Ont.

Engineers
Boiler-makers
Founders
Machinists

Tank Work
Smoke Stacks,
Grey Iron and Brass Castings,
Special Machinery Made to Order

tenders for the equipment were: Pittsburgh Filter Mfg. Co., $8,850; Interstate Filter Co., $9,100; New York Continental Jewel Filtration Co., $9,350; Roberts Filter Mfg. Co., Inc., $12,000. Tenders for the building were: Canadian Engineering and Construction Co., $13,350; McAllister & Taylor, $13,500; Pigott & Healy, $14,490; Dick Construction Co., $16,350; Secord & Sons, $16,826. The total cost of the plant will be about $27,000. The plans have been approved by the Provincial Board of Health, but the contract has not yet been let, awaiting final action of the council, which will probably be taken this week. E. H. Darling, Hamilton, Ont., is the consulting engineer.

## PERSONAL

**Mr. Bramble**, formerly advertising manager of the Goodyear Tire and Rubber Co., has left to become general sales manager for the Canadian Chicle Co.

**J. W. Coleman**, manager of the Boss Tool Nut Company and also associated with the Consolidated Equipment Company, is making a business trip to Winnipeg and other points in the West.

**J. L. Hynes**, for some time Toronto representative for the Armstrong, Whitworth Co., of Canada, has been transferred to the head office at Montreal, being appointed sales manager for that district.

**E. T. Malone**, who has has been representing Armstrong, Whitworth Co., of Canada, Limited, in the Hamilton district, has been appointed district representative for Ontario and has been transferred to Toronto, his headquarters in the future.

**James A. Stairs**, of New Glasgow, N.S., has gone to Detroit, where he is to take charge of the shell department of the Harmon Motors Co., now devoting their plant to the production of munitions on a wholesale scale. He has had considerable experience in the line of industrial activity developed out of the war, and will, in his new position, have approximately twelve hundred men to direct.

Word was received by Henry J. Waddie, 51 Markland street, Hamilton, manager of the Canadian Drawn Steel Company, that his nephew, Norman Waddie, M.M., had been killed in action. Pte. Waddie enlisted in the Imperial army in Edinboro', Scotland, and was awarded the medal on March 21 for distinguished gallantry. Only a few days after, about the first week of April, he was killed. He is the seventh connection of Mr. Waddie to give his life for his country.

**W. H. Farrell**, terminal superintendent of the Grand Trunk Railway in Toronto, has been offered and accepted the position of general manager of the Algoma Eastern Railway Co., with headquarters in Sudbury. Mr. Farrell will have charge of the line from Sudbury to Little Current, and will assume the duties of his new position on July 1st, Mr. Farrell has been in the Grand Trunk service thirty-four years, for twelve of which he has been superintendent of the Toronto terminals. The new general manager, like almost all successful railwaymen, started at the bottom, and by his untiring devotion to duty worked his way up to his present position.

## TENDERS

The Department of Public Works, Ottawa, will receive tenders endorsed "Tender for Repairs to Pier at Cobourg, Ont.," until 4 p.m. on Monday, June 17, 1918, for the construction of repairs to the Langevin pier at Cobourg, County of Northumberland, Province of Ontario.

**Petrolia.**—Tenders will be received up to Monday, June 17, 1918, for construction of three bridges for county of Lambton. Plans may be seen after June 8, at the residence of John McCallum, County Highway Commissioner, Alvinston, Ont., and at the offices of A. S. Code, Alvinston, Ont., County Clerk's office, Sarnia, and Town Clerk's office, Petrolia, Ont.

## TRADE GOSSIP

**Changing Offices.** — The British-America Nickel Corporation, Ltd., have sent out notices to the trade that they are removing their offices from Toronto to the Citizen Building, Sparks Street, Ottawa.

**Galt.**—Repair work will shortly be undertaken on the bridges over the Grand River. Seven steel spans were damaged by the ice during the spring floods. E. H. Darling of Hamilton will have the work in hand, although the work is already under way in charge of W. C. Greenfield, structural steel erector.

**Winnipeg.**—The Canadian Northern Railway will spend in the neighborhood of $2,000,000 in improvements and the construction of new branch lines this year, according to an announcement made here. Almost all of this work will be done on lines west of Port Arthur and a great deal of it in Saskatchewan and Alberta.

**A Question of Cars.**—Speaking of the coal supply, one authority writes: That coal cannot be satisfactorily stored, as it is so bulky that the investment in space would run into a prohibitive cost. Besides, bituminous coal is liable to spontaneous combustion or deterioration, therefore the mine operators require a steady stream of cars to remove the coal as it is mined. When these cars are not at the mines when the men arrive for work they see it is no use and go home. Thus the day's work is lost. If the men lose several days in a week they demand higher wages. The situation is, therefore, put up to the railways, and their management of it this year will be a severe test of the new government control. If it wins out the cause will have achieved a great triumph.

**Hydro Electric Power For Sale**

THE Pembroke Electric Light Company has a surplus of 1,200 to 1,500 H.P. Rates approximate $18.00 per H.P. per annum for twenty-four hour service.

Good labor conditions. Liberal inducements to manufacturers. C.P.R., G.T.R., and C.N.R. connections.

Industries requiring female labor especially desired.

E. PULLAN WIPERS & WASTE CO. LIMITED TORONTO

KINDLY MENTION THIS PAPER WHEN WRITING ADVERTISERS

**Conciliation Boards.**—The Minister of Labor has established boards of conciliation to deal with the dispute between the British Columbia Electric Railway Company and its employees and with the dispute between the Canadian Northern Railway Company and its freight clerks, etc., members of the Brotherhood of Railway Employees.

**Order Causes Alarm.**—Dealers in high priced automobiles are face to face with the prospect of closing up shop. This will be the result, if the order-in-council prohibiting the importation of cars valued at over $1,200 goes into effect. Jewelers, fruit dealers and imported rug dealers are also vitally interested in the order that will stop these commodities coming into Canada. All admit that the proposal has come as a "bolt from the blue." The fruit dealers, who declare that the measure will have a tremendous effect on their business will hold a meeting as soon as the terms of the order are made public.

**Increased Output.**—Efforts are already under way to relieve the coal situation in the Canadian West. In Alberta a large increase is noted in the amount of coal mined and exported. A report just issued states that the total amount of domestic coal mined in 1918 during January, February and March amounted to 810,972 tons, as compared with 744,700 tons mined last year during the same period. In the bituminous field the amounts were 712,313, as compared with 650,319 tons mined last year. Anthracite was 39,409 tons in 1918, as compared with 37,817 last year.

**Will Rebuild Enderton Block.**—C. E. Enderton announced that the Enderton block, corner of Portage avenue and Hargrave street, Winnipeg, which was partially destroyed by fire last winter, will be rebuilt this summer. The restored building will be practically a replica of the original. The restoration wil cost about $200,000, it is estimated. Owing to the high cost of material and the difficulty of securing it, the work will be done by day labor, and W. A. Irish, contractor, has been placed in charge of the work. The block will be ready for tenants by the autumn.

**Patents Issued.**—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained. H. E. Angold and Wm. Duddell, distance operated mechanisms and signals connected to electric supply systems; Wm. T. Bell, Leonard W. Jones and Wm. H. Watson, motor plow; Wm. J. P. Cloakey, dust collector; Wm. Hooker, atmospheric gas burner; H. and A. Saunders, safety catches for brooches and the like; Henry P. Baird, air moistening and filtering attachment for radiators; Shurly-Dietrich Co., Limited, saw blade; G. & J. Weir, Limited, control device for rotary pumps; Gutta Percha & Rubber, Limited, the manufacture of sheet rubber; the Williams, Greene & Rome Co., Limited, reversible cuffs.

Scandinavia Belting
Is a Good Belt for Dusty Places

In cement plants, saw mills, grain elevators, and lots of dust-trap belts, Scandinavia belts are very satisfactory for the mill operators.

You know how wearing grit is to a belt, and you want a belt that will not come apart when only partly worn through.

"Stand-laval" belts are of such a kind that there are no plies to come apart it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one, please. It will be a pleasure to us both.

Federal Engineering Co., Limited
172 John Street, Toronto

Note—Do not use "bar" or "stick" belt dressing on textile belts.

METAL STAMPINGS

We are manufacturers of stamped parts for other manufacturers.
We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.
We can finish steel stamping in Nickel, Brass or Copper
Send us a sample order.

W. H. BANFIELD & SONS
372 Pape Avenue, Toronto, Can.

## HELP WANTED

WANTED—MECHANICAL AND ELECTRICAL [illegible] Write [illegible] Canadian (c24m)

WANTED—EXPERIENCED DRAUGHTSMEN [illegible] Canadian Machinery. (c24m)

WANTED—DRAUGHTSMAN JUNIORS, ON [illegible] state age, experience, [illegible] Apply Box 403, Canadian Machinery. (c3m)

FOREMAN WANTED, ENERGETIC, ACTIVE [illegible] particulars as to age, experience, nationality and [illegible] Box [illegible] Canadian Machinery. (c24m)

WANTED PRACTICAL WORKS FOREMAN, [illegible] well experienced in the manufacture of gasoline [illegible] to handle men to get production in machinery manufacture. State age, experience and wages expected. Box 429, Canadian Machinery. (c25m)

PRACTICAL WORKS SUPERINTENDENT with high mechanical and executive ability; competent to handle men to get production in machinery manufacture. State age, give references and wages expected. Steady employment for right man. Apply Box 434, Canadian Machinery. (c27m)

FOUNDRY FOREMAN WANTED FOR IRON foundry, making engine castings and intricate cored work, a first class foreman. Must be thoroughly up-to-date in modern labor-saving methods, and capable of producing high grade [illegible] Shop and appliances unexcelled, best of position furnished. Apply to Box 433, Canadian Machinery. (c27m)

WANTED—CHIEF ENGINEER FOR MANUfacturing plant; a master mechanic, capable of [illegible] charge of boiler room and [illegible] repair department, must be able to handle men. Apply Box 440, Canadian Machinery. (c26m)

MECHANICAL ENGINEER TO TAKE CHARGE of production in small plant manufacturing machine tools, must be technical man, with drafting room and shop experience, excellent opportunity for advancement with progressive firm. State full particulars and salary expected in first letter; quick engagement essential; replies confidential. Box 437, Canadian Machinery. (c26m)

FIRST-CLASS FOREMAN FOR TOOL DEpartment must be capable of making detail drawings and practical experience on punch and dies. Apply Box 438, Canadian Machinery. (c25m)

WANTED A FOREMAN FOR TIN AND sheet metal shop; one who also understands roofing and accustomed to the handling of men. Apply Box 439 Canadian Machinery (c26m)

## FOR SALE

FOR SALE—FOUR USED 24" DAVIS CHUCKing Turret Lathes, in good repair. William Hamilton Company, Ltd., Peterboro, Ont. (c26m)

FOR SALE TWO 18 x 8 HEAVY ENGINE lathes in good condition, taper attachments. Box 432, Canadian Machinery. (c27m)

FOR IMMEDIATE SALE, 150 NO. 1, 10 NO. 7 Racine Saws, excellent condition. The Peck Rolling Mills, Limited, Montreal, Que.

AUTOMATIC SCREW MACHINES—TWO ⅞-inch Cleveland automatic screw machines for sale. Kawneer Manufacturing Co., Limited, Guelph. (c24m)

FOR SALE—RETURN TUBULAR BOILER 16 ft. long x 65 inches diameter, seventy-six 3½ inch tubes. Passed for 85 pounds steam. Full iron front, shaking grates and fittings. For price apply Canadian Hart Wheels, Limited, Hamilton (c25m)

FOR SALE SUBJECT TO PRIOR SALE — 1 Bertram two-spindle thread Miller for 18 pdr. shells. Good conditon. $400. Also one single-spindle Bertram thread Miller, $275; also one 2 x 24 J. & L. turret lathe, now fitted with chuck for 18 pdr. shells. $400. Steel Furnishing Co., Ltd., New Glasgow, N.S. (c24m)

ONE FITCHBURG ENGINE LATHE 24" x 10'; one 10" x 6 McKenzie Lathe with 10" 4-jaw Skinner self-centering Chuck, one 15" Shaper with graduated head and table; two Crosby No. 30 Presses; one McGregor-Gourlay No. 19 Press; one 3/16" Rivetting Machine; one Combined Hand and Foot Hammer; one No. 1 Champion Blower; one set 52" bending rolls for light sheets. Dillon Mfg. Co., Oshawa, Ont. (c25m)

FOR SALE CHEAP—ONE 30 K.W. GENERAtor set 220 volts D.C. Ideal Engine—Westinghouse Generators on sub-base—switchboard. One 20 K.W. generator set on sub-base, same as above. These two sets are in perfect condition and we offer decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland & Gladstone Sts., Winnipeg. (c26m)

## POSITIONS WANTED

FORGE SUPERINTENDENT HAVING WIDE experience on shells, all sizes; also miscellaneous heavy forging, desires change. Box 435, Canadian Machinery. (c27m)

EXECUTIVE POSITION WANTED BY MAN who has held position as Secretary of a company for a number of years. Experienced on credits, purchasing, and office management, but would prefer purchasing end of business for foundry, machine, or ordnance shop. Best of reasons for change. Apply to Box 431, Canadian Machinery. (c24m)

GRADUATE IN MECHANICAL ENGINEERing, seven years' experience, married, will be open for engagement about June 1st. Address Box 426, Canadian Machinery. (c24m)

POSITION AS TOOLROOM OR MACHINE shop foreman; 20 years' tool and general machine shop; 14 years foreman; British, American and Canadian experience in manufacturing small and medium interchangeable parts; familiar with latest up-to-date methods; good organizer, energetic, tactful. Open for position after June 15th. Box 436, Canadian Machinery. (c26m)

USE OF CUTTING FLUID ON WELLS SELF-OPENING DIE.

# CUTTING FLUIDS AND THEIR APPLICATION

By J. W. Morrison

SINCE the introduction and use of high speed steel great improvements have been made in machining processes and many alterations in machine design have occurred for the purpose of increasing production. Changes and standardization of tool shapes and arrangements have been made, and indeed practically no department of this important subject has failed to make considerable advancement.

In the case of cutting fluids, as used in machining operations, however, though notable progress has been made it has not kept pace with other phases of metal cutting, many shops still clinging to ideas of tool lubrication that were in vogue many years ago and long since abandoned by the more progressive factories. Indeed, many shops still do much metal cutting dry, no lubricant of any kind being used, except perhaps for finishing or threading.

### Advantages Not Recognized

It is well known, of course, that if a first class job of threading or forming is to be done, cutting lubricant, in most cases oil, must be used, but that great gains may be secured by the use of a cutting fluid in all steel turning and cast iron is not so generally understood. As a rule, too, it is recognized that a cutting lubricant should be used on turret lathe and screw machine work, but it is not so extensively appreciated that equally as great, or even greater, advantages may be realized in the same way on all turning and other similar operations.

Interesting proof that such conditions exist is found in the report of a canvass made for the purpose of securing data on the use of cutting fluids. The answers to the questions sent out show that of thirty-eight answering the inquiry as to the best lubricant for cutting steel, brass and cast iron, only, twelve made mention of brass and eleven of cast iron. The answers to the question as to whether a cutting fluid reduced the power required and if the action was simply that of a coolant were, in the main, answered vaguely, or not at all. As a matter of fact some declared that power consumption was reduced and others were equally positive that it was not.

Eleven years ago F. W. Taylor, in a paper entitled "On the Art of Cutting Metals," read before the American Society of Mechanical Engineers, declared that "the copious use of a cutting fluid properly applied makes possible an increase in cutting speed of 40 per cent. when turning steel, and 16 per cent. when turning cast iron," and it is surprising, in view of this very explicit statement, made so long ago, that the use of cutting fluid is not more general and its economies more widely recognized. As Mr. Taylor pointed out, experiments to discover the best tool shapes and other similar matters, such as tool pressure, difficult of determination, have not served to effect a gain of more than 2 to 5 per cent., whereas the determination of the value of cutting lubricant is a simple matter and makes for far larger economies. It is also interesting to note that while the gain of 40 per cent. cutting speed in the case of cutting steel was with high-speed steel tools, yet there was a gain of 33 per cent. when self-hardening steel was used and 25 per cent. gain when carbon steel tools were used.

### Stream Lubrication

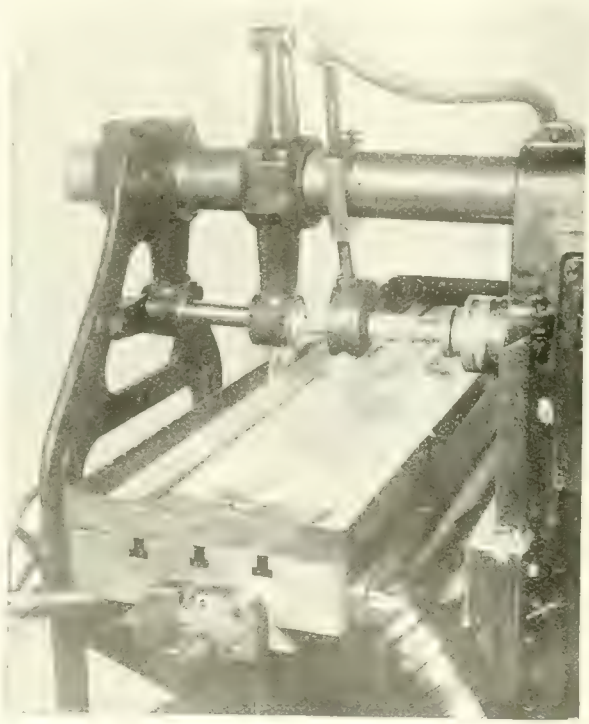
Undoubtedly the most conspicuous demonstration of the efficacy of cutting fluids in increasing cutting speed is that resulting from stream lubrication as practised by the Cincinnati Milling Machine Co. This system of tool lubrication consists of flooding the cutter with a cutting lubricant applied at the rate of about twelve gallons per minute and at a much higher pressure than is customary. This system effectually prevents any appreciable heating of the cutter and thus permits much higher cutting speeds than previously obtained in milling practice, the increase in cutting speed being from eight to twelve times greater. The advantage of lubricant in this case is suf-

as to when and where to use cutting [illegible] to the choice of the kind to be used we find an even greater diversity of opinion and practice. For example, some factories use a high grade cutting oil for all cutting requirements, others mix the oil with kerosene or a mineral oil, and still others use a cutting compound. Factory conditions such as kind or type of machinery, material cut, etc., differ, and of course call for differing treatments, but these will not entirely reconcile the divergent practice. The canvass, already mentioned, brings out this difference of opinion in a very instructive manner. Out of thirty-eight answers to the question of the best lubricant to use on steel, cast iron and brass, there were seven different recommendations for steel and eight for cast iron; some advocating lard oil, others a mixture of oils, and some favored a water mixture. This disagreement still further indicates the lack of unity in practice and is evidence enough that the subject has not as yet received the thorough study and investigation which it merits and is absolutely necessary if it is to be as well understood as other phases of metal cutting. For example, the uses and limitations of high speed steel are very well known, but cutting fluids have never received a general investigation that in any way approaches that accorded high speed steel.

The recommendations of different manufacturers of cutting fluids do little to unify or clear the subject since they very frequently overlap and often are not substantiated by sufficient data. Undoubtedly some of this difference is due to excessive enthusiasm, but the greater part are based on a partial knowledge and statement of the case. For example: the advocate of a water mixture may state that his material works successfully for threading, and while this is undoubtedly true for some kinds of work yet such mixtures are not universally satisfactory for this work when the thread is large and must be made to close limits with a good finish. The claims of the advocates of "mineral lard" oils as well as cutting compounds and soluble oils are often identical, and in many respects serve no other purpose than to confuse the user.

### Investigate Relative Value

An investigation of this subject in a shop should definitely determine the relative value of the different kinds of [illegible] fluids for the work being done and the best manner of applying and using the fluid. Such an investigation should be made of all the cutting operations which are carried on to any considerable extent. For example, if turned and threaded bolts are made in considerable quantities they will merit a special investigation. Similarly forming work will also require special attention, for the most economical cutting fluid in the case of bolts obviously will not be at all satisfactory for difficult forming. Similarly, even on the same kind of work it may not be advisable to use the same cutting fluid on a high speed automatic machine as a hand machine, for the lubricant will enter the bearings of the automatic, and unless it possesses considerable lubricating properties, will cause excessive wear and must be rejected on this account, even though it may be very satisfactory as far as the work to be machined is concerned. Thus the investigation must not only take into account matters pertaining to the actual metal cutting but also various other local conditions. For this reason a general investigation can never serve to cover completely every possible condition even on the same material, but the principal value of such investigations lie in the fact that they furnish an advanced starting point for more detailed studies and save much preliminary work.



STREAM LUBRICATION DEVELOPED BY THE CINCINNATI MILLING MACHINE CO.

### Properties to Consider

In making a comparative study of cutting fluids, there are numerous properties that must receive attention, and these are:—thermal lubrication, cleanliness, acidity, evaporation, tendency to cling to chips and work, and if a water mixture is used, such as a soluble oil or cutting compound, consideration must then be given to the stability and ease of making up the solution.

Considering these items in some detail it is found that the thermal properties are among the most important, for the tool must be kept cool if it is to do maximum work, and in many cases it is also important that the work be kept cool as well. The fluids containing a large proportion of water are naturally the most effective coolants, while oils are much less effective distributers of heat. An oil will absorb only about half as much heat for the same temperature rise as a water mixture.

Good lubricating properties are also essential since this plays an important part in some kinds of cutting, as already pointed out. In many instances the lubricating property is essential to securing a good finish of the work. Additional to this it is important because of its effect upon the machine for the cutting fluid will tend to wash the lubricating oil away, especially if it is strongly alkaline, and thus cause rapid deterioration of the machinery.

Cleanliness of the cutting fluid has much to do with the general appearance of the shop, but possesses particular importance because [illegible] of the workman. Some fluids tend to retain dirt, dust, fine cuttings, etc., in suspension, while others quickly throw it down when they become quiet. Oil is particularly inclined this way, and some plants have found it advisable to instal purifying apparatus. This sterilizes and filters the oil and restores it to nearly the original condition and value. From the standpoint of its value in cutting properties the cleaning process is valuable, for it is scarcely necessary to say that oil is more efficacious when clean than when laden with impurities.

A cutting fluid having a strong acid reaction is injurious to the machinery, and is likely to be so to the operator.

The rate of evaporation has a direct effect upon the consumption of cutting fluid and therefore upon its cost. The thermal properties of the liquid have a bearing here, for unless the fluid has large heat-absorption capacity its temperature will rise and rapid evaporation take place. In the case of water solutions the evaporation loss is easily replaced by adding more water, but when oil is used more material must be added to make up for this loss. When the cutting is quite heavy and oil is used the evaporation loss is often considerable, and in all cases should be thoroughly investigated.

### Loss via Chips

Then tendency of a cutting fluid to cling to the chips is of importance, for in this way much of it may be lost from being carried away on the chips and work. By the use of a centrifugal oil extractor practically all of the fluid

clinging to the chips may be saved provided the chips are in such shape that they can be placed in the extractor. This cannot always be done in the case of the work, on account of its size, etc., and much of the fluid may thus be carried away. This tendency is much more pronounced in the case of oil than a water mixture, and as a matter of fact it will probably not pay to attempt the extraction of the latter. The extractor cannot fully recover the oil in the chips and this loss must be figured into the cost of using any fluid. It will be sufficient to cite but one instance to demonstrate that the loss from this source may not only be appreciable but a very large factor in the cost of using a cutting fluid. When using kerosene as a cutting fluid it has been found that 140 pounds of chips from a lathe will contain as much as a gallon of oil, and since a lathe can make at least 2,000 pounds of chips per day the loss of fluid from this source may easily amount to as much as $1.50 per day per machine, which is certainly well worth considering. A fluid such as lard oil will cling to the work and chips in much greater quantities than kerosene, and this, in addition to the fact that oil is far more expensive, simply serves to emphasize the importance of this item in a cost analysis.

When a water solution such as soluble oil, cutting compound, or soda water is used, the ease with which the solution is prepared is also a matter of importance, for there is often considerable difficulty, particularly in cold weather. Some of these materials readily enter into solution with water, while others require considerable stirring. If the water is cold, as in the winter, this trouble is often accentuated, and in some cases hot water must be provided. Most soluble oils are readily mixed with water and very much more so than the cutting compounds, and both of these are much more readily prepared than soda water mixture. Oils, of course possess a great advantage in this respect since no mixing is required, and this characteristic should always be given consideration in all cases. The writer has seen some soluble oils that in winter would go into solution only after very prolonged stirring.

### Water Solutions

The stability of water solutions is a matter of no small moment for these cutting fluids differ widely in this particular, some being so unstable as to make them almost useless. Undoubtedly every one familiar with shop practice has noticed how difficult it is to keep soda water solutions in proper condition, due to the tendency of the oil to separate; the oil coming to the surface gathers dirt, dust, etc., and takes the form of a scum on the surface of the settling tanks. This of course weakens the solution, may make it unequal to the demands of the work, or, if the solution is still satisfactory, the excess oil is wasted.

Cutting compounds sometimes act in somewhat the same way, while soluble oils occasionally separate and form a jelly-like mass, the solution becoming nothing more than a slightly colored water, useless for cutting purposes. This failure may occur very soon after mixing has been completed or it may not be for several days. Such failures add to the expense of using the fluid in many ways, such as delays and frequent renewals, all of which is unnecessary expense. The writer does not wish to be understood as being opposed to the use of such cutting fluids as a class, for he has often found their use both economical and decidedly advantageous from an operating standpoint.

### Lard Oil Versus Others

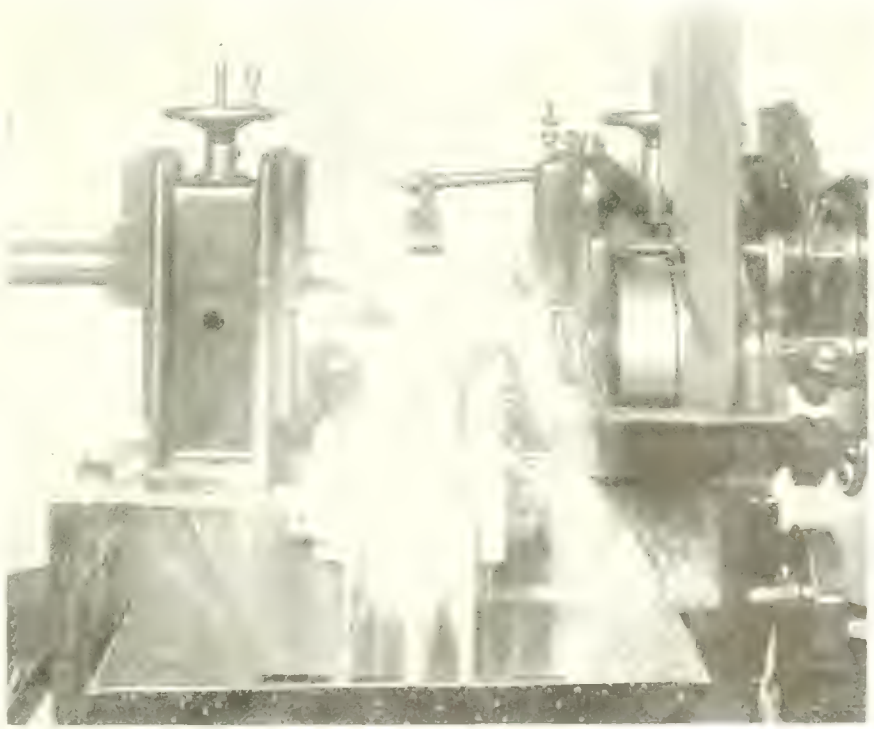
These properties of cutting fluids are those which determine their value and should be thoroughly investigated in each and every case where selection is to be made for a particular purpose and the relative value of various kinds and brands established. In a degree, selection is always made on this basis, but as a rule many of these characteristics are not distinctly recognized and so are seldom given proper weight. However, the need of a more careful selection is daily becoming more apparent and this demands accurate knowledge of the different cutting fluids that their value be placed upon a more definite and comparable basis. There is a well established tendency in many shops to use a first-class lard oil for all cutting purposes on the basis that it is safe and will be certain to prove satisfactory. It is true that this policy now proves satisfactory, but would it if the users had exact knowledge of its relative value? It is perfectly safe to say that in many instances it would not be found altogether acceptable. Already in this paper it has been pointed out that a cutting compound will sometimes replace oil and make a considerable increase in the output of the machine. This is simply an example of the advantages always secured from complete information as compared to partial knowledge. Any investigation of this subject should be as complete as circumstances will permit, and every effort made to reduce the performance to a definite and concrete basis as possible, thus furnishing opportunity for an intelligent choice.

The different kinds of cutting fluids are legion, but the great majority are little used. In general there are four classes of cutting fluids in use yet, while they have some features in common, each forms rather a distinct class. These four classes are—oils, cutting compounds, soluble oils, and so-called soda water. All four are very widely used in machine shops.

### Oils

Beginning with oils, those in more common use are lard oils of various grades, so called mineral lard oils, and mixtures of these with various other oils such as parafine, engine or kerosene oils. These latter being much less expensive than the base oils in the mixture are used on this account and serve to dilute and decrease the cost per gallon of the mixture.

The best lard oils are very expensive and are most frequently used on highly automatic machines, etc., and for difficult threading and forming. In these uses its good lubricating properties play an important part. The manufacturers of the mineral lard oils claim equal merits for their product, but the choice should always hinge upon definite knowledge rather than habit or guess or upon



STREAM LUBRICATION DEVELOPED BY THE CINCINNATI MILLING MACHINE CO.

the recommendation of some one not entirely familiar with the prevailing conditions. In general oils heat up readily and so are not the best of coolants, but in lubricating properties they are usually very fine and are not injurious to the machines. All oils do, however, have a very considerable tendency to keep impurities in suspension, thus deteriorating their quality and endangering the health of the workmen. Oils are sometimes unduly acid which is injurious in every way to the machines and workmen alike, but this defect seldom occurs with good grades. Steel, when finished with oil as a cutting fluid usually has a dull lustre.

### Cutting Compounds

Cutting compounds are usually white, or brownish white, in color, and of a somewhat greasy nature. An analysis shows they consist almost entirely of water, soft soap, mineral and animal oils. The water content of a good quality will run from 30 to 35 per cent., soft soap 20 to 25 per cent., mineral oil 18 to 20 per cent., and animal oil 15 to 20 per cent. The writer has known of some compounds running as high as 60 per cent. water, but this occurs only in the very poorest grades. From this it is obvious that much of the purchase price goes for water, and when using this material care should be taken to see that the percentage of water does not run over that agreed upon in the beginning and at the same time the tests were made. It is also very desirable to check the other constituents as well.

### Purchase to Specification

Such material should always be purchased to definite specifications. This material, mixed with water in varying proportions, to meet differing needs, ic widely used for many different machine shop operations. Containing as it does a large percentage of water it is a good coolant and very inexpensive as compared with oils, but its lubricating properties are much less.

The ease of mixing and stability of the solution varies with the different brands, and in some cases with the temperature of the mixing water, some kinds having a tendency to separate in cold water. The evaporation on heavy work is rather rapid ,but this of course is not serious since more water can be added. In some cases the compounds become rancid, acquire a very disagreeable odor, and, being a menace to the health of the workmen, require frequent renewal. There are, however, many compounds on the market which are not affected in this way even in the hottest weather. The effect of the solution on the machine is of major importance, for it must not be such as to cause an absence of lubricant on the bearing surfaces as this will result in undue and unnecessary wear and other depreciation. While a cutting compound necessarily does not possess the lubricating properties of oil, yet in very many instances and on many kinds of work it does possess sufficient lubrication to keep machine wear at a proper minimum. Generally speaking, the solution is clean, about the only disagreeable features being its tendency to foam. Some manufacturers have what they call a non-foaming compound, but its qualities are usually not quite equal to those of the regular mixture.

To use cutting compound to the best advantage it is desirable to vary the percentage of water, depending upon the kind of work to be done, but while this somewhat complicates the use of the material, at the same time it is usually necessary in order to meet the requirements of the work and likewise to secure maximum economy. The determination of the proper mixture in every case is a matter for trial. The writer has found that compound can frequently replace oil on many kinds of work done on hand screw machines, and when this is possible a great saving is thereby effected. In one instance a saving of 85 per cent. in the cost of the cutting fluid was made in this way on a very few machines, the actual saving per year being over $430.00. The work produced consisted of very carefully made bolts, rings and other similar screw machine products, the work done when using compound being fully equal to that done with oil, the deterioration of the machines not being hastened and tool wear not noticeably increased. The feasibility of such a change is dependent upon the local conditions, and every case must be carefully investigated. As a rule the finish on steel is bright.

SIMPLE CUTTING FLUID SYSTEM FOR SMALL SCREW MACHINES

### Soluble Oils

Soluble oils are a widely used cutting fluid and are very successful in many instances. They consist of an oil, or a combination of oils, so treated as to make them soluble in water, the resulting mixture being white and closely resembling a cutting compound solution. As a rule they dissolve in water very readily and for this reason are very convenient for use. The oil itself is very expensive and therefore the mixture is often considerably more expensive than a cutting compound mixture. The thermal properties are much the same as those for cutting compounds, though there have been some brands on the market of very little cooling capacity. The lubricating properties of the mixture are, of course, dependent upon the proportion of oil present and varies with the differing formulae. The solution is clean, very rarely, if ever sufficiently acid to cause trouble, while the loss due to evaporation is of but little moment since it can easily be made up by adding more water.

The ease of mixing is usually such as to cause but little trouble, though there have been brands marketed which were almost impossible to dissolve, especially in cold water. The stability of the solution is usually all that could be desired, though the writer has known of soluble oils which would not stay in solution more than a very few days. After this they required renewal. This is a very serious matter from every standpoint, for the quality of the solution varies constantly and interferes with the machine operations and the frequent renewal makes the costs excessive. The mixtures must be varied with differing conditions and selection can be intelligently made only after a trial. The finish of the steel where such a solution is used is bright.

### Soda Water

The so-called soda water mixtures are very widely known and have been used for a long time, but on account of the various disadvantages connected with

this mixture are being replaced to a very considerable extent by other cutting fluids. Such a solution consists of water, an alkali such as soda ash, or sal soda, and a saponifiable oil such as a lard oil for example. The alkali reacts with the fatty acids of the oil, causing chemical action, the result being a white cutting solution similar in appearance to the other water solutions already described. The solution is used for screw machine work, drilling, milling, etc. The cooling properties are excellent, but its lubricating properties are practically nothing, and because of the presence of mu- alkali the machine wear is excessive. The free alkali becomes deposited upon the bearing surfaces, and because of its nature drives away the lubricating oil, causing rapid wear. This is a very serious matter and usually results in rejection when this is realized. A decrease in the quantity of alkali can of course be made, but the writer has yet to know of a case where the action described above did not occur in some degree.

The cleanliness of this solution does not compare favorably with that of other water solutions for it soon becomes rancid and has a dirty scum on the surface of the tank at all times. On account of the free alkali this solution is never acid, while the evaporation and consumption are about the same as for other water solutions. It is difficult to prepare on account of the trouble of dissolving the alkali and the necessity of very carefully proportioning the ingredients.

The stability of the solution is sometimes far from what might be desired for some of the oil has a tendency to separate, though when properly mixed this is negligible. The solution is used for the same class of work as the other water mixtures and the bright finish noted with their use also obtains here.

CUTTING FLUID ON THE NUTTER & BARNES AUTOMATIC [illegible] OIL MACHINE

### Greater Use Possible

As already noted the use of cutting fluids is yet in its infancy as far as general practice is concerned, for many make no use whatever of them, and but few to anything like the extent they might advantageously. The great need is a thorough investigation of the subjects that will cover different kinds of cutting fluids and the manner of using them, both as to quantity and kind of material and work to which they are adapted. Some users have undoubtedly made such an investigation to the extent their operations require, but such knowledge is not generally available and has therefore but a limited use as yet. The present critical times demand the utmost possible use be made of existing machinery and all such facilities, and this, together with economies certain to result, should be a sufficient incentive to cause all machine shops to investigate and give this subject their serious and studied attention.

## NEW FOUNDRY FOR DARLING BROS.

THE construction of the new grey iron foundry now being built for the engineering firm of Darling Bros. of Montreal, marks the third extension to their plant during the past two years. While the additional expansion has resulted from considerable activity in connection with government contracts the greater volume of business has come from the increased demands upon their ordinary lines of engineering specialities. Their present activities are treble that of three years back and it is anticipated that with the completion of the new iron foundry the pre-war business will be quadrupled. The foundry, which will be a modern reinforced concrete and brick building with a frontage of 96½ feet on Ottawa street, and a depth of 112 feet, is expected to be in operation in about two months, and will be, when completed, one of the most modern and up-to-date for its size in the country. The plant will be equipped with a 6-ton cupola and every modern facility for economic and rapid production, including a five ton Sprague electric crane and the latest types of molding machines. In addition to supply the castings for their own requirements the firm contemplate catering to the general trade.

## RECOVERING METAL FROM FURNACE FUMES

By M. L.

There has just been erected at Sheffield a plant for the recovery of metallic particles and other by-products from furnace fumes. It was discovered about 1906 that by passing gases containing dust of solid and liquid principle to various forms and types of industrial electrodes, charged with the high voltage of 50,000 to 100,000, dust and liquid particles could be carried over to one or other of the electrodes. Since that time the inventors of the process, which is of American origin, have not only successfully recovered valuable properties from waste fumes, but have also got rid of smoke and the smoke nuisance. Metals, such as zinc, silver, copper, lead and aluminum, have been recovered, besides coal-tar and other by-products of commercial value. The experiments made at Sheffield are yielding satisfactory results, and other firms in Britain are now beginning to instal the plant in an encouraging fashion. The British Government have made one installation. The installation appears to provide a thoroughly efficient remedy for the smoke nuisance, but the treatment of ordinary carbon fumes is unlikely to prove a profitable proposition, and for that reason the installation of the plant purely as a [illegible] within the realms of probability.

**The Trade Balance.** — Sir Thomas White, Minister of Finance, will again visit Washington for the purpose of discussing the exchange situation. He will confer with Lord Reading, British Ambassador in Washington, and with the United States Treasury Board. The Minister will leave almost imediately. Since the last conference was held on the question in Washington the Government here has taken certain steps toward curtailing imports. The amount involved in the embargo, however, is but infinitesimal as compared with the unfavorable balance of trade as between Canada and the United States, which is computed at about $400,000,000.

# Time Study Data: Methods of Analysis and Use

## Accurate Data Well Arranged and Classified Essential to Any Efficient Cost System —All Complex Operations and Processes Are Commendable to Analysis, Resolving Into a Small Number of Machine Operations

By M. H. Potter

There are two methods of making time studies. The old-style method, i.e., each job that goes through the shop has the watch held on it and the over-all time of the job noted. In the course of a year there will accumulate a number of records and the time required for each. This is in advance of the earlier method of guess work. Such a method of fixing the cost is slow and expensive.

The second method, which enables accurate data to be secured, is the method of analyzing all machine and work handling operations into the most elementary details, separating each particular part of an operation into its smallest elements and tabulating these together. The elements are then grouped into classes and filed in such a manner that any element of any particular class can readily be found when desired. It is then a comparatively easy matter to fix a time for a job which has never before been done in the shop, and the time so set will be accurate and fair alike to employer and employee. The method of consistent machine analysis will enable the manufacturer to accumulate in a comparatively short time an amount of time-study data which will be applicable to a large portion of the work in his shop. Every addition to these data will widen the scope of his time-study and rate-setting department.

### Method

This method of elementary analysis is practical, although at first sight it may not appear to be easy. The natural tendency is for a manufacturer to obtain first a study of the time required for the most important job or the job that recurs the oftenest in his shop. He is by this method making the biggest step forward in shop efficiency.

The building of a certain machine is a rather complex proposition, at least we will assume that it is, requiring the machining and assembling of a great variety of different pieces. Nevertheless every one of these many parts can be resolved into a comparatively small number of machine operations. Machine work can be divided into the following divisions: The turning or grinding of cylindrical surfaces, the planing or milling or grinding of flat surfaces, and the boring or drilling of holes. This gives us our first sub-division of our time-study element. We have a means of ascertaining with accuracy just how long it will take to produce the piece in the shop if we know the time required to turn a certain cylinder to a given diameter, to plane or mill its ends and to drill a hole through it. It is necessary to add the time required to put it in the lathe, planer or milling machine, and drill press, and also to remove it. We, therefore, first sub-divide our time studies by the machines on which they are made.

### Machine Study

Each machine should be studied in detail, in order that the various operations which can be performed upon it may be combined with one another to represent the sequence which is to be followed in producing any certain piece. The number of individual operations that a lathe will perform is comparatively limited. We may engage or disengage the back gears; we may shift the belt from one cone to another; we may change the feed gears; we may move the carriage along the ways; we may operate the cross-slide; we may set the compound rest; we may throw in or out the cross-feed; we may move the tailstock from one position on the way to another; we may set the tailstock over one way or the other for the purpose of turning tapers or make use of the taper turning attachment should the lathe have one; we may connect the cross-slide to it or disconnect it; we may put on or remove a steady rest; we may remove the face plate and put on a chuck; we may remove or replace head and tail centres; we may put in the tool post or remove from it one or another type of tool; we may start or stop the machine; we may engage or disengage the nut or screw cutting; we may advance or withdraw the tail centre. These operations represent practically everything that can be done with an engine lathe, yet the combination of these elements in varying sequences and numbers will enable us to perform pretty nearly any job which may come to that machine.

It is obvious, therefore, that the method of analyzing a machine and its handling time will be productive of real results in the shape of accumulated data more quickly than will any other method of time study. It is true that the machine operations must be analyzed and studied completely before the data can be used. A partial study will be of little value in setting a general run of tasks, for in all probability the particular machine item which may be needed in setting the task on a given job will be the one on which no time study has been made. The complete study of a large number of machines does not require such a great amount of time as might be imagined.

### Time Studies in Connection With Inserting and Removing Cutting Tool

We have seen how time-study data should first be sub-divided according to machines, and then according to machine operations. We will go into this detail a little more closely to illustrate how finely the different machine operations should be sub-divided before they are tabulated for recombination into elements forming complete jobs. One of the commonest operations which occurs in lathe work is the placing of the cutting tool in the tool post prior to cutting metal, and the removal of it from the post upon the completion of the machine operation. This is made up as follows:

Get tool from tray at end of lathe.
Measure height of tool.
Put packing in tool post.
Put tool in tool post.
Set tool in position.
Tighten tool-post set screw.

Removing the tool from the post is tabulated as follows:

Loosen tool-post set screw.
Remove tool to tray at end of lathe.

While the operation of tool handling is analyzed in the detail explained above, it is in practice put on the instructions issued to the men in the form shown. The value of the detailed analysis is this, that if the total time is questioned as being too long or too short we have available the elements which enter into its making up, and can easily ascertain in which particular part of the study the workman was at fault.

The principle remains the same, whatever the operation may be. There are many jobs the individual operations of which occupy many minutes, and if these operations are questioned the detailed analysis is always available to show what the workman is expected to do and how long each element should require. If a workman is unable to complete his job in the time fixed a comparison of his work with the detailed analysis—the watch being held while the comparison is made—will frequently show that he is exceeding the analysis time in one particular element only, and a correction of his work as regards this element will often bring his performance well within the time called for by the time study.

### The Combination of Individual Elements

Let us now return to the consideration of the combination of individual elements for the making up of a unit time for a job. In the first table which we cited, those giving the time for putting an ordinary turning tool in the tool-post, we have a list of elements common to any tool. In establishing unit times for handling different types of tools than the ordinary round-nose turning tool we have only to add to the elements for that tool these items which are different from the tool under consideration. We have already seen what change is made in the analysis for a square-nose tool. For a chamfering tool or a facing tool we have only to add to the analysis for the turn-

ing tool the item of setting the tool to a bearing. For a thread tool we have to add the additional item, "Set tool to thread gauge." Thus in determining unit times for handling any type of tool in the lathe we can simplify both the time study and the tabulation by first studying the handling of that tool which contains all the elements which the other tools require, and then studying those particular elements which are different in the remaining tools.

After having determined a series of elements of various characters, such as the putting of the tool in the tool-post, these can be combined with others similarly determined to form complete fundamental operations which enter into the completion of a definite job. Such a fundamental operation is the setting and starting of the cut. In the compilation of the time-study data with which I have been working the setting and starting of cuts on a great many different sizes of lathes and with a variety of cutting tools are tabulated as follows:

Put tool in post and tighten.
Start machine.
Set calipers.
Set cut by calipers.
Put in feed.

This tabulation is for the setting and starting of a cut with a round-nose rough-turning tool. In writing the instruction card, this item should be listed. "Set and start cut."

After the cut has been completed, if the tool is to be removed, the following items are taken together from the analysis to give the time for stopping the cut and removing the tool:

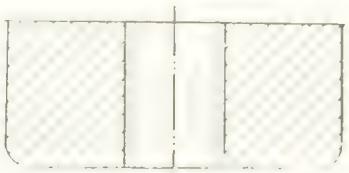
Throw out feed.
Run tool half-way back.
Run back carriage.
Stop machine.
Loosen and remove tool.

On the instruction card this item would appear "Stop machine, remove tool." If, however, the tool was to be run back to the beginning of the cut and an additional cut taken, we would use another set of items appearing in the same tabulation, as follows:

Set cut by calipers.
Put in feed.
Throw out feed.
Run tool half-way back.
Run carriage back.

It will be observed that in the last tabulation the same items appear as in the former ones, except that they are grouped slightly differently. The items of removing the tool and stopping the machine are omitted, as these operations are not performed when repeating a cut without removing the tool from the tool-post. These tables are a good example of how elementary time-study enables one to build up unit times for different operations. Having the data necessary to fix a time for setting and starting a cut, analyzed in the detail exhibited in the first two tables above, it is necessary to make a study of the time required for an additional cut. The man familiar with machine work can list without any trouble just what motions the lathe hand goes through in running his tool back and restarting the cut. These are as given in the table above. Having the time for these various items exhibited in the earlier tables, it is only necessary for him to set them opposite the items in the new table and total them; he then has the proper unit time for [illegible] additional cut with the same tool.

## SPECIMEN INSTRUCTION CARD



| | Prep-aration | Hand-ling work | Hand-ling tools | Ma-chine | Re-ing |
|---|---|---|---|---|---|
| 1. Removing face plate from arbor | X | | | | |
| 2. Put chuck on lathe | X | | | | |
| 3. Move tailstock back | | | | | |
| 4. Grip piece in chuck | | | | | |
| 5. True piece in chuck | | | | | |
| 6. Put rough-turning tool in post | | | | | |
| 7. Change feed and speed | | | | | |
| 8. Set calipers | X | | | | |
| 9. Set and start cut | | | | | |
| 10. Rough-turn dia. close to jaws as convenient | | | | | |
| 11. Stop machine, run tool post back | | | | | |
| 12. Change to rough facing tool | | | | | |
| 13. Move carriage to end of piece | | | | | |
| 14. Set and start cut | | | | | |
| 15. Rough face base | | | | | |
| 16. Stop machine, run tool post back | | | | | |
| 17. Change to finish-turning tool | | | | | |
| 18. Set and start cut | | | | | |
| 19. Finish-turn dia., close to jaws as convenient | | | | | |
| 20. Stop machine, run tool post back | | | | | |
| 21. Change to finish-facing tool | | | | | |
| 22. Set and start cut | | | | | |
| 23. Finish face base | | | | | |
| 24. Stop machine, move carriage back | | | | | |
| 25. Change to rough-boring tool | | | | | |
| 26. Set and start cut | | | | | |
| 27. Rough bore hole | | | | | |
| 28. Run carriage back, change to finish tool | | | | | |
| 29. Set and start cut | | | | | |
| 30. Finish bore | | | | | |
| 31. Run carriage back, stop machine, remove tool. | | | | | |
| 32. Turn piece end-for-end in chuck | | | | | |
| 33. True piece in chuck | | | | | |
| 34. Run carriage up | | | | | |
| 35. Put rough-turning tool in post | | | | | |
| 36. Set and start cut | | | | | |
| 37. Rough turn dia. | | | | | |
| 38. Run carriage back | | | | | |
| 39. Change to finish-turning tool | | | | | |
| 40. Set and start cut | | | | | |
| 41. Finish turn dia. | | | | | |
| 42. Stop machine, change to rough-facing tool | | | | | |
| 43. Set and start cut | | | | | |
| 44. Rough face end | | | | | |
| 45. Stop machine, run tool post back | | | | | |
| 46. Change to finish-facing tool | | | | | |
| 47. Set and start cut | | | | | |
| 48. Finish-face end | | | | | |

| 50. Remove piece from chuck to floor | | | | | |
| 51. Remove chuck | | | | | |
| 52. Replace face plate | | | | | |
| 53. Clean machine | | | | | |
| Preparation time | | | | | |
| Handling work | | | | | |
| Handling tools | | | | | |
| Handling machine | | | | | |
| Removing metal | | | | | |
| Total time for job | | | | | |

### Preparation of an Instruction Card

The application of the principles of elementary time study to the preparation of an instruction card for a job of lathe work will now be taken up. The instruction card shown in this connection is modified in form [illegible] pare the machine for receiving the work and restoring it to its standard condition after the job is done; handling time of the work itself—that is, the time required to place the work in the machine, remove it, and perform any manipulating which are necessary [illegible]

different classes of elementary times may be separated for purposes of illustration.

In all time study the work is divided [illegible]

truing, leveling, squaring, and similar operations; tool-handling time, or the manipulation of the cutting tools, putting them in the tool-posts, removing them, etc.; machine-handling time, which includes all machine manipulation, such as moving the carriage, changing speeds, setting and starting cuts and similar operations; machine time, which represents the time actually employed by the machine in removing metal. The first four sets of times are determined by elementary time study.

Referring now to the instruction card, we see that it calls for the machining of a cast iron piece, which is to be finished all over and have the hole in the centre bored. It is assumed that a roughing and finishing cut is to be taken for every operation, and that different tools are to be used for turning and facing. An inspection of the card will show that the first operation is the removal of the face plate, which normally remains on the machine and the replacement of it by a four-jawed independent chuck. The sequence of operations followed in machining the work is clearly shown by the instruction card, including the turning of the work end for end.

It will be noted that, although there are 553 different items listed, the actual number of operations performed is considerably less. A study of the card will show that most of the operations recur from time to time.

### Time Totals

Turning now to the totals, it will be observed from the time involved that considerable time is required to prepare the machine for the work and to clean it up after the job is finished. The interesting feature, in most cases, is that the machine is working only a little over 50 per cent. of the time. The importance of studying closely the manipulation both of the machine and of the work; second, the value of time study in increasing the relative producing time of the machine, is obvious.

The mere fact that there is a standard by which the performance of the workman can be measured will in itself tend to increase the effort of the man to do his best. The standard being present, any failures can be investigated, and that particular point wherein the man failed can be pointed out to him and corrected.

## ITALIAN CHEMIST PROPHESIES "DAY OF LIGHT"

WHEN the rays of the sun strike the green leaves of a plant, carbonic acid gas and water vapor or moisture are gathered in from the air and these within the remarkable laboratory of every green leaf are turned into sugar. At the same time oxygen is set free, back into the air. The reaction requires heat, and the sun's rays provide it.

The plant operates other chemical factories and these transform sugar into starch, which is stored in the seeds to feed each sprouting plant until it gets big enough to grow green leaves and make sugar and starch for itself. Starch is also transformed within the plant into gums and cellulose, and the structural basis of wood is cellulose. Please observe also that the sun provides the heat for all of these reactions.

### Fuel Combustion

When we burn wood or coal we reverse the process; we drawn upon the oxygen that has been set free into the air when this or some other tree grew and we combine or burn it with the carbon acid gas and water again. That is the great cycle of vegetable life, beginning with carbonic acid gas and water and ending in carbonic acid gas and water. The reversed reaction gives off heat instead of requiring it, and that is why we burn wood or coal: to get the heat back that the sun provided long ago. White smoke is mostly steam and carbonic acid gas. Black smoke is mostly carbon that got frozen out in the fire or couldn't find oxygen enough to combine to carbonic acid gas again.

Professor Giacomo Ciamician, of Bologna, in an address before the Eighth International Congress of Applied Chemistry, asked why we use only the fossil energy of the sun—which is what we do when we burn coal. Why not get the power direct? If plants do this thing, he insisted there must be a way. There is plenty of water, it is easy to make carbon dioxide, and there is the sun. The point is, of course, to make available the radiant energy of the sun's rays and put it to use, which the plants can do and we cannot—as yet—for lack of adequate research. The professor felt sure, however, that this riddle will be solved some day, and then he made computations as to what we may do after the way has been discovered.

Using the sun for only six hours of every twenty-four on desert lands, and making generous allowances for good measure and waste, he concluded that the sun would deliver in energy taken direct from its rays, instead of by our roundabout method of recovering it by burning coal, the daily power value of 2,500 tons of coal per square mile. We mine in the United States about 600 million tons of coal a year. The desert of Sahara alone receives every day in solar energy the equivalent of six billion tons of coal.

### Looking Forward

Then he showed a long list of photochemical processes which indicate progress in research towards "The Day of Light,"—towards sun power. He prophesied that in time tropical countries will be thickly populated, that on their arid lands there will spring up industrial colonies without smoke or smokestacks but with forests of glass extending over their plains and glass buildings everywhere. Inside of these will take place those processes that are still the guarded secrets of trees and grass. But when these are mastered human industry will make them bear far more than nature does. Nature is not in a hurry and mankind is.

So some day it may not even be necessary to use fuel any more or to worry about the supply or the price. With this enlightenment, when it comes, we shall not need coal, so long as the sun shines. And when the sun ceases to shine we shall not want anything at all. Maybe the man who would shortly have made this discovery has been killed in the war!—*The Little Journal.*

## CARBONIZING COMPOUND IS IMPROVED BY ENGLISH CHEMIST

Charcoal with barium carbonate as "actifier" is well known as a case-hardening compound, but in its ordinary form has many disadvantages. On the other hand it gives a high carbon content to the surface of the work, which is a very desirable feature.

The objections to the old form of the compound were chiefly that the barium carbonate and the charcoal were mixed by various mechanical means. Barium carbonate being much heavier than charcoal, the two always separated in the pot whilst in use, and to a certain extent before use, owing to the handling of the bags. The result of this was that the barium carbonate collected in the bottom of the pot making a large amount of dust, and at the same time ceased to be an actifier to the charcoal on top, thereby causing patching work, i.e., one part of the article was sometimes harder than another.

The importance of this is obvious, and has frequently been the cause of trouble in various types of machinery, and efforts to overcome the difficulties of mechanical mixture, whereby the carbon is impregnated with a soluble salt of barium or calcium and is converted into the carbonate by a later process, have resulted in the preparation of a compound named "Munsite" after its inventor, Leonard C. Munsite, an English chemist and metallurgist.

By this process the barium is held in the charcoal so that it is impossible to separate them, dust is reduced to a minimum, and tarnish is avoided. As barium carbonate is infusible, it does not separate after heating and the much-wanted uniform hardening is obtained.

THE latest claimant to economic fame is the Australian cactus plant. Prominent British investigators are of the opinion that the luxuriant growth and capacity for starch production possessed by this plant may ultimately result in its becoming a world source of alcohol when conditions render the universal use of this fuel inevitable for internal combustion engines of all kinds.

**J. R. Baxter and Co.** have acquired the sole selling rights in Canada and the United States for the "Desy" line of special shell machinery.

# Producing Sound Steel With Special Ingot Molds

## The Inventor of the Gathmann Ingot Mold Advocates the Elimination of Blow-holes by Allowing the Formation of Piping at the Upper End—Many Molds of the Type Described Have Been in Use With Satisfactory Results

By Frank C. Perkins

THE accompanying illustrations, Figs. 1 and 2, show a train of Gathmann 20 x 24 x 80-inch ingot molds and a one-ton ingot made on the big-end-up mold, while in drawings Figs. 3 and 4 may be noted the details of construction of the Gathmann molds. The photograph Fig. 5 shows two ingots cast in a standard mold and in a differential mold, the former having a piping discard of 27.3 per cent. and a blow hole discard of 41.2 per cent., while the ingot cast in the differential mold shows a piping discard of only 5.17 per cent. and no blow hole discard whatever. In the photograph Fig. 6 may be seen split ingots made in Gathmann mold and also in a regular type of mold. In considering the commercial production of sound, homogeneous steel ingots and blooms, Engineer Emil Gathmann has found that there is a decided difference of opinion among the producers of steel as to what constitutes commercially sound steel.

He says: "Some metallurgists insist upon having, for certain grades of steel, a so-called "open steel," i.e., one which contains numerous blowholes of varying sizes, and consequently but little volume of true pipe, although a central intermittent shrinkage cavity often extends well down into the ingot. Such blowholes and pipe are expected to weld up during rolling or forging, because their surfaces are not oxidized. Even if this be admitted, included slag particles and a high degree of segregation are bound to be present in the product of such ingots. Blowholes are the result of an oxidized heat, and all heats, unless made or finished in the electric furnace, are oxidized more or less. Subsequent deoxidation, or rather degasification, either in the ladle or in the mold, or in both, is necessary to reduce or prevent blowholes. As is well known, a greater yield of billets or sheets is secured from the ingot by allowing the formation of blowholes, but this is undoubtedly obtained at the expense of the quality of the product. Decided segregation of carbon, phosphorus, and sulphur, as well as small included slag particles, undoubtedly exists throughout the greater portion of all so-called open steel and cannot be removed by cropping."

FIG. 1- TRAIN OF GATHMANN 20 x [illegible] INGOT MOLDS.

Engineer Gathmann further maintains that "the first requisite for sound, homogeneous steel ingots and blooms is, therefore, in my opinion, so to treat the steel in the furnace, ladle and mold that "piping" steel is produced. The line of demarcation between harmful and so-called "harmless" blowholes is practically impossible to define. Is it not, therefore, the better and safer practice to use means for the elimination of blowholes and correspondingly reduce the segregation and allow the formation of a well-defined shrinkage cavity or pipe at the upper end of the ingot? With the relatively cheap deoxidizers available at the present time, e.g., ferro-silicon, aluminum and titanium, there is no commercial reason why all steel should not be thoroughly degasified."

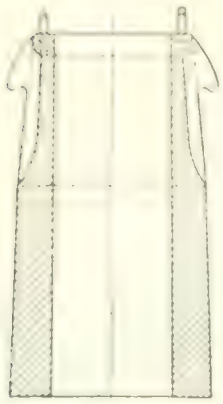
### Theory of Mold

The inventor of these special molds claims that a degasified steel being provided, the method of freezing or solidifying the liquid steel into an ingot, and the subsequent working into blooms and thence into various products, is of great importance in reducing the crop or scrap portion of the steel, due to segregation and pipe. How to accomplish this reduction at a minimum expense and without upsetting the administrative mill practice of present plants is the problem. It has been my experience that the solidifying of an ingot made from steel which has been practically deoxidized or "killed" in the ladle or in the mold depends upon the shape of the horizontal cross-section of the ingot at its various planes from top to bottom, and also upon the thickness and consequent heat-absorptive power of the various parts of the mold walls. An ingot with its larger horizontal cross-sectional area at the top is without question the best shape for obtaining the important "lag" in solidification of the steel, and whenever such large-end-up ingot can be conveniently used, it is the best practice to do so. Nearly all of the large mills are, however, so equipped for handling and stripping the ingots that it is practically impossible to do this without extensive changes in equipment.

FIG. 2. GATHMANN INGOT SHOWING ABSENCE OF PIPE IN MAIN INGOT.

It is declared that it is necessary to employ means in ordinary big-end-down ingots to greatly accelerate the freezing and solidifying of the lower and middle portion of the ingot, and thus provide liquid metal to compensate for the decrease in volume caused by the contraction during solidification of the ingot. This has been accomplished by giving the lower 70 to 80 per cent. of the metallic mold in which the ingot is cast a much greater degree of heat-absorptive capacity than the upper 30 or 20 per cent. thereof.

It was attempted to accomplish this by ribbing the lower exterior surface of the mold in order to provide increased



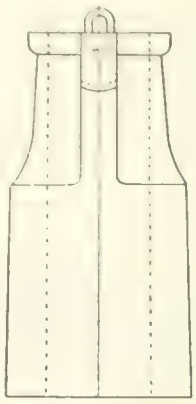


FIG. 3—GATHMANN INGOT MOLDS

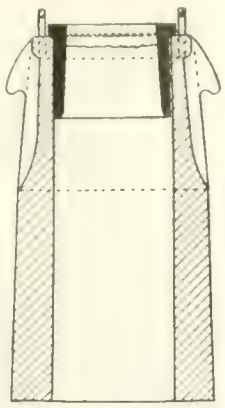

FIG. 4 GATHMANN INGOT MOULD SHOWING SINK HEAD APPLIED.

capacity, and making the upper mold wall thinner and less heat-absorptive.

Many hundreds of molds of the kind shown in Fig. 5 have been in daily use under usual furnace and mill conditions during the past year, and designs of molds have been made and established in actual practice for from 1 to 10-ton ingots. In order to insure an ample supply of liquid steel to compensate for the shrinkage in the upper portion of the ingot in very dense, quick-setting steel it was found advisable to use walls of a material of poor heat conductivity in the uppermost portion of the mold to supplement the differential effect obtained by the combination of the heavy and thin mold walls; in other words, to provide a sink-head.

It is stated that the usual type of sink-head resting on top of the mold, or rigidly secured in the upper part of the mold cavity, was found not to fulfill all the conditions necessary in a commercial sense, primarily because of the high cost of such sink-heads when efficient. Sink-heads of this kind must be of sufficient thickness and strength to hold the liquid steel without cracking or breaking. Even a slight crack or break in the sink-head is sufficient to form a fin of steel and hang the ingot during its vertical shrinkage, thus causing surface cracks and defects in the body thereof.

### Type of Sink-Head

The drawing Figs. 3 and 4 shows a method of freely suspending within the mold cavity a sink-head made of poor-heat-conducting material. This type of sink-head, in conjunction with the heavy-wall mold, has given most excellent results, and is in regular use by several of the largest high-quality steel works in this country, in conjunction with the mold walls with a heavy body and thin top. Such a mold, if properly designed, will produce a sound, homogeneous ingot with about a 20 per cent. top crop, which is about 15 per cent. less than is usually necessary in ingots of like grade of steel made in the old-type mold.

The photograph Fig. 6 indicates split ingots of vanadium-nickel-chrome steel, one cast in a mold of the standard type and the other cast in a Gathmann-type mold. With a sink-head in combination with the type of mold described the crop necessary to eliminate the pipe and segregation is approximately 10 to 12 per cent. of the cold ingot. When the ingots are allowed to solidify in the mold the pipe will be formed to its maximum depth.

A fairly early stripping and rolling of the ingot is advocated, the actual time of stripping being governed by the cross-section of the ingot and no expensive change in administrative practice is required in the production of ingots by this method, which is in use by many steel plants.

It is claimed that it may be readily incorporated in the practice of any of the large steel works without upsetting in any manner the casting or mill practice. The physically homogeneous condition of the ingot of primary importance in producing sound blooms and finished products. The method of blooming such ingots is, however, also of importance. It has been my experience that in some heating and rolling practice there is danger at times of actually forming a false pipe, or rather fissure, in the ingot. This is especially the case where the ingot has been allowed to solidify and become cold in the mold. Many mills have found it good practice to strip the mold from the ingot before its central portions have entirely solidified and place it in the soaking pit or furnace in a vertical position, allowing the temperature to become equalized and the final feeding, due to shrinkage, to occur while in the soaking pit. The ingot is then rolled while the interior is hotter and more plastic than the exterior. Great care must, however, be exercised that the ingots be allowed to remain in the soaking pit until the steel is entirely set, because rolling with any green steel in the ingot will produce spongy centres. It is therefore necessary to determine the proper heating period before pulling specific sizes of ingots for blooming.

Regarding the best method of reducing ingots to blooms, it is best to effect most of the reduction in butt-to-head passes, and a marked improvement in crop reduction is obtained by this method of rolling, especially when the piped section is confined to the upper 20 per cent. of the ingot. Irrespective of any heating and mill practice which it may be desired to use at any specified mill, the physical condition of cold ingots split open for inspection is undoubtedly the true index to the value of any method for producing sound, homogeneous steel.

### Ideal Considerations

It is maintained that the theoretically ideal method of making sound, homogeneous steel is undoubtedly with the big-end-up mold, because the increasingly large area of the ingot towards the top compensates automatically for any irregularities in the temperature of the steel or in the teeming practice.

The photograph Fig. 2 shows a split ingot produced by the Gathmann method under normal conditions with the big-end-up practice, the crop for piped

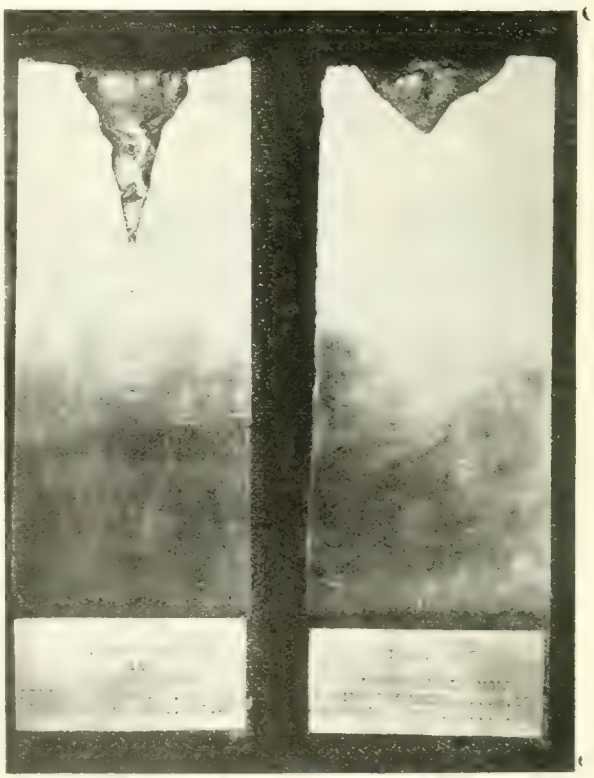

FIG. 5

FIG. 6.

section being approximately 5 per cent. The inventor recommends in the usual mill practice where cars or bogies are used for carrying the molds, the heavy-walled body, light-walled top, big-end-down mold, as shown in Figs. 3 and 4 and also the use of a suspended sink-head of non-conducting material to fully compensate for the contraction in the upper portion of the ingot.

It is pointed out that these molds and methods are applicable for the production of any grade of steel cast in ingots, and will invariably improve the quality and lessen the top crop, and thousands of tons of these molds have been made of both direct and cupola Bessemer iron, giving excellent service as to number of heats per mold, while reports from mills using these methods and molds show that an important saving has been effected thereby in reduction of crop ends, and in making good, sound, homogeneous steel for every purpose.

## U.S. EXPORTS OF MANUFACTURES

The United States has suddenly becomes the world's largest exporter of manufactures. Prior to the war, according to a compilation by the National City Bank of New York, that country held third place among the nations of the world as an exporter of manufactures, being clearly outranked in this line by Great Britain and Germany. With the opening of the war, however, and the suspension of Germany's export trade the United States took rank next to Great Britain as an exporter of manufactures, and with the enormous foreign demand upon its factories it has now passed Great Britain in the race, and stands at the head of the list of nations exporting manufactures.

The world's exportation of manufactures in 1913, the latest normal year in international trade, were, according to the bank's compilation, stated in very round figures—Great Britain $2,000,000,000 of [illegible] tures exported, Germany $1,675,000,000, United [illegible] gium approximately $400,000,000, Austria-Hungary $375,000,000, Italy $275,000,000, [illegible] $250,000,000, Japan $225,000,000, Switzerland $200,000,000, India $125,000,000, Sweden $100,000,000, Canada $77,000,000, Russia $70,000,000, and Spain $50,000,000, all of these figures being in very round terms. Thus the grand total of manufactures entering international trade in the year before the war was about $8,000,000,000, of which the United States supplied about one-eighth, or in round terms $1,000,000,000.

About ninety per cent. of the manufactures entering international trade in 1913 was the product of countries now at war. In certain of the countries, notably Germany, Austria-Hungary, Belgium and Russia, exportation of manufactures was suspended, and in others, notably France, Italy and Netherlands, the exportation was greatly reduced. In still others, however, notably the United States, Canada and Japan, the production and exportation of manufactures greatly increased following the war. In the case of the neutral countries of Europe there was little change, and the official figures of Great Britain show comparatively little change, though presumably they do not include all of the war material sent out of that country by the Government, especially that going to France.

The chief countries which show a marked increase in exportation of manufactures during the war are the United States, Canada and Japan.

## A WORTH WHILE BOOK FOR INDUSTRIAL LEADERS

Facts are facts, and in recognizing their existence and endeavoring to bring them before their fellowmen in a convincing yet withal not discouraging manner, Dr. H. B. Gray and S. Turner state that their main object in this, as in other directions, is to create the consciousness of a need rather than to dogmatize on the methods to be applied. "Eclipse or Empire" is the title of a recent book by these authors, and while the title savors of Teutonic ambition, the work itself is in direct contrast, being more a recognition of facts which a blind prosperity has induced the Anglo-Saxon nations to ignore than a statement of national greed.

The following extracts are a few of the many distinctive passages which characterize the book and give it a lasting charm for every man who lives by or is influenced by organized industry.

### The Message

"There is a soul in industry."

"A perfect machine is not the mere metal out of which it is welded. It is rather the embodiment of human sweat and tears of human sacrifice. Viewed thus broadly it is an embodied tribute to the invincibility of the human spirit."

### Ideals of Business

"The wealth accumulated by the man who makes business his life work, and thereby becomes a creator, is a mere fraction of what that work has saved for the community."

"A business—that is, a scientifically organized system of creation succeeds only when it is cheaper to buy its products than not to buy them."

"The business man of to-day....visualizes that in the process of creating and providing he must be efficient."

"In the future "the rewards of industry will be for those only who render great services to the community at large.'

### The Human Factor in Business

"The rewards for those who do great things, whether masters or men, must be ample and generous."

"The reward for increased speed and increased product should consist in the concession of fewer hours and higher pay."

"It is indeed an economic law....that the greatest possible production is always in the interests of the community at large."

"....the discovery and application to business of the laws of efficiency, thus eliminating waste, which arises from the blind use of antiquated methods. Mathematically put, the equation stands thus: Low profits + low wages = high profits + high wages = waste. What is waste? It is the sprawling of the human factor aimlessly over its environment."

"The first and hardest thing to be done is to kill the microbe of prejudice which eats away the vitals of trade. That microbe must be put in a brain furnace; for it breeds myriads of offspring, but all bear one common surname—waste."

"Man is infinitely the most wonderful and complex instrument, as well as the most essential factor, which the commander-in-chief of a business has to handle....In man there is dynamic force—he must either develop or he must shrink."

"It matters but little what a man is to-day—the great matter is what he desires and intends to be in one, or two, or three years' time. He is not a mere machine with two hands and two feet—but a living, pulsating energy. He has a trinity of powers—spirit, mind, and hand, and the least of these three is hand. For it is only the spirit to do, and the mind to create, that can make the hand move at all."

### Science and the State

"We venture to say that nothing in any department of industrial life is being done in 1916 as effectively as it will be done in 1926."

"The progress of our nation will depend on the rate at which we turn the principles and theories of science into terms of ascertained facts."

## TOOLS FOR CUTTING-OUT, BORING, AND FACING A BLIND HOLE

By F. Seriber.

A BORING bar of irregular design that was used for cutting out a blind hole and boring the same is illustrated by the accompanying drawing, Fig. 1 showing the bar for boring, counterboring and facing a large surface is shown.

The object in making a bar for cutting out a blind hole in place of drilling was to eliminate as much as possible the strains which would have been otherwise set up in an aluminum casting of thin section.

First, to be specific, it was necessary to cast the work with the hole in it as otherwise the sections around the hole would be so thin they would draw in the casting and cause a poor structure. Second. on account of the thinness of the casting wall it would not support the strain of cutting out by means of a large drill without distortion, consequently recourse was made to the tool shown in Fig. 1 which is provided with a cutting-out tool in its end.

Having described the object of this tool by referring to the illustration, its construction will be obvious from the reference letters. The boring bar proper A is made with a taper shank which fits into the spindle of the machine. At the opposite end a cutting out tool B is shown; this tool is clamped in place by the wedge C which has two screws D in it and is dovetailed in place. This tool is provided with radial clearances so it will cut free and is tapered back slightly for clearance; this tool is also backed up with an adjusting screw E. At right angles to this cutting out tool a flat boring cutter F of the usual type clamped in place by means of the screw G is placed and in operation; the cutting out tool goes completely through the thin wall of the work and cuts it out, thereby incidentally making a thin disc out of the centre of the hole; following the cutting out tool the flat cutter bores the hole to size for reaming.

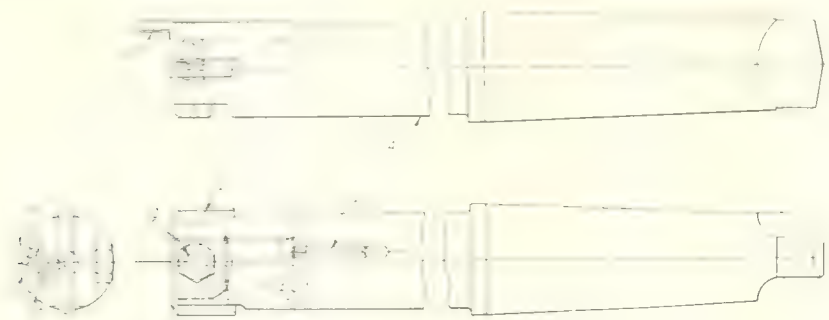

FIG. 1.—BAR FOR CUTTING OUT AND BORING BLIND HOLE.

To accomplish this the bar which is designated as F has a flat cutter G in it of the usual type held in place by a wedge H; this cutter enters the work at the right hand end and as the hole C is the same size as the counterbored hole B, the short hole at C is the first part bored, passing through the hole a pin cutter J which has an adjusting screw in back of it which is not shown and is held in place by the screw K, bores the hole A, while of course at the same time the cutter G counterbores the hole B.

For toughness this boring bar is made of a machine steel forging and at L a cutter M is placed for facing; this is

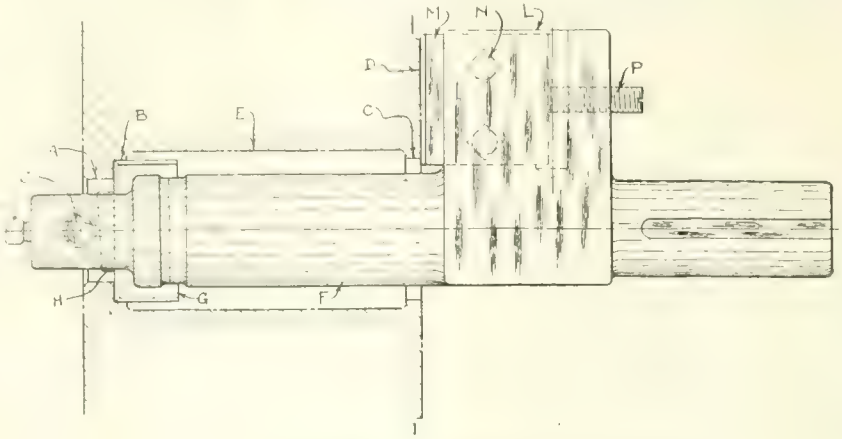

FIG. 2.—BAR FOR BORING, COUNTER-BORING AND FACING.

Referring to Fig. 2 the work operated upon is shown in section and the hole therein is cast out. The finish on this part consists of boring the hole A, counterboring the hole at B, boring the hole C and facing the surface D, while the hole E is a recess which is cast in place and requires no finishing.

securely held by the two screws N and is backed up with an adjusting screw P, while the entire boring bar is held in the turret of a hand-chucking machine upon which the work is done.

On these boring bars both cutting rake and clearances were provided in the usual manner for the material being operated upon, in the first instance, aluminum, and in the last mentioned cast iron.

## SIMPLE CLAMP CHUCK FOR SHELL BORING OPERATION

By M. H. Potter

Considerable trouble as been experienced in securing an efficient and easily operated chuck for holding the larger sized shells (6 inch or over) during the boring operation. In order not to have too much stock to remove in the finish turning operation the shell must be held on centre, not only that but due to the heavy boring cut and the heavy pressure at the end of the shell the chuck must have a positive grip.

The chuck herewith illustrated is simple but positive, inexpensive to make and easily operated; it has been used with marked success by female operators in the boring of many thousands of shells.

Fig. 1 shows the shell in position in

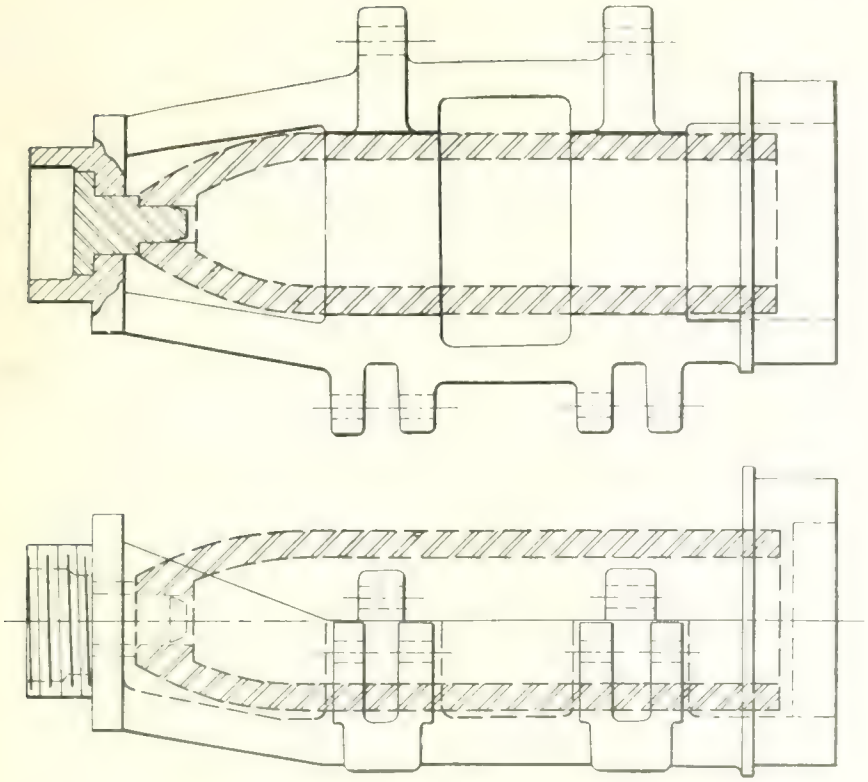

FIG. 1.

the chuck, and Fig. 2 the end view showing the hinged clamp. The babbited steady rest shown in Fig. 3 is of the ordinary type, being split through the centre to take up the wear. The chucks were bored out to size on the machine on which they were used to insure good alignment.

Fig. 4 shows the canvas sling which was used, in connection with an air hoist, to place the shell in and out of the chuck. It will be noticed, Fig. 4, that one ring (at the end) is larger than the other, the smaller one being passed inside the larger one when the sling is placed around the shell. During the operation the sling remains around the shell, the loose end being forced inside the chuck. To place the shell in the chuck or to remove it, the shell is slid slightly forward; it can then be raised upwards.

Fig. 5 illustrates the same type of chuck adapted to a closed-in shell.

## RESEARCH COUNCIL IN U. S. BECOMES PERMANENT

At the request of the President of the United States the National Academy of Sciences is to perpetuate the National Research Council which latter body was organized in 1916 by the Academy at the request of the President.

The work accomplished by the council [illegible] co-operation of military and civilian agencies in the solution of military problems, demonstrates its capacity for larger service and under the aegis of the academy its duties will be as follows:

1. In general, to stimulate research in the mathematical, physical, and bioligical sciences, and in the application of these sciences to engineering, agriculture, medicine, and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare.

2. To survey the larger possibilities of science, to formulate comprehensive projects of research, and to develop effective means of utilizing the scientific and [illegible] dealing with these projects.

3. To promote co-operation in research, at home and abroad, in order to secure concentration of effort, minimize duplication, and stimulate progress; but in all co-operative undertakings to give encouragement to individual initiative as fundamentally important to the advancement of science.

4. To serve as a means of bringing American and foreign investigators into active co-operation with the scientific and technical services of the War and Navy Departments and with those of the civil branches of the Government.

5. To direct the attention of scientific

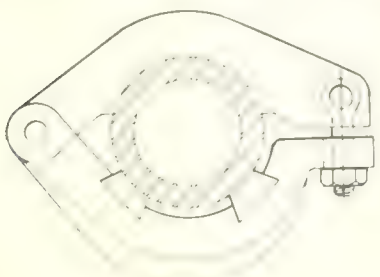

FIG. 2.

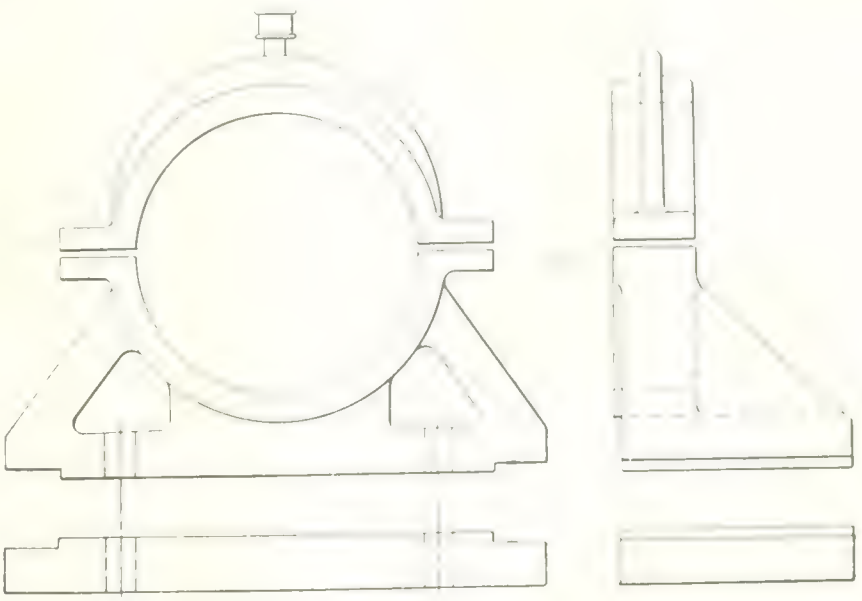

FIG. 3.

to the present ... industrial ... with the war, and to aid in the solution of these problems by ...

... and collate scientific and technical information, at home and abroad, in co-operation with governmental and other agencies, and to render such information available to duly accredited persons.

Effective prosecution of the council's work requires the cordial collaboration of the scientific and technical branches of the Government, both military and civil. To this end representatives of the Government, upon the nomination of the National Academy of Sciences, will be ... as members of the council, as heretofore, and the heads of the departments immediately concerned will continue to co-operate in every way that may be required.

## BRASS FOUNDRY OF THE ST. LAWRENCE WELDING COMPANY

EXPANSION of the brass foundry business has been a natural consequence to the abnormal and rapid development of the shipbuilding industry. The production of brass castings for engine parts and interior fittings is one of the necessary requirements incidental to marine activity, this being due to the imperative need of installations that will give satisfactory service under atmospheric and weather conditions; in addition to this artistic appearance has much to do with brass fittings for ship equipment. The heavy demand for brass and bronze castings has resulted in the development of many foundries for this purpose, some of these having shown remarkable expansion during their brief period of operation.

From a small beginning about the first of November, 1917, when two initial pit furnaces were installed with a capacity of 500 lbs. each per day, the brass foundry of the St. Lawrence Welding Company has shown a capacity increase of approximately 800 per cent. in less than six months, the total daily production at the present time being about 4½ tons. The output is obtained from a battery of eight 500 lbs. pit furnaces and one oil fired tilting furnace, with a daily capacity of 1,000 lbs. A feature of the pit installation is the utilization of hard coal as fuel, with natural draft, the furnaces being arranged in sets of four. The method of firing has shown a great saving over the use of coke, as the hard coal is less destructive on the crucibles.

One portion of the shop is decked over to from a small but serviceable pattern room. The firm at present are principally engaged in the production of brass castings for ships' telegraphs and other general marine work; also considerable business in bronze bearings for heavy duty engine and rolling mill work. A. M. Barry is the managing director of the company.

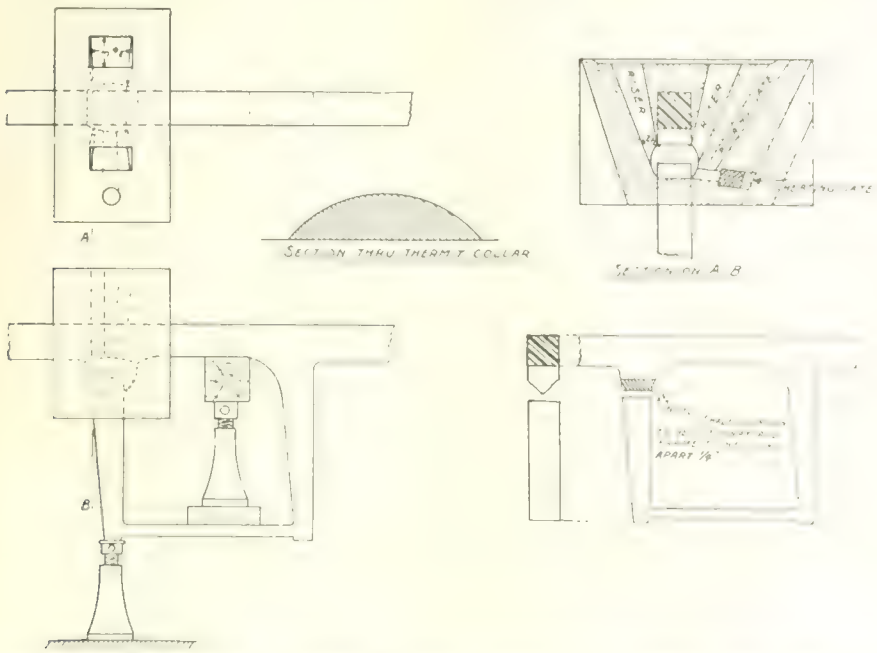
## WELDING LOCOMOTIVE FRAMES

THE welding of a fracture in a vertical frame member of a locomotive sometimes presents difficulties, but this operation is simple if care is taken in preparing the fracture for welding and in placing the risers so that no gases, slag or molding material can be trapped in the weld. It is considered that the best practice is to cut out the fracture as shown in the accompanying drawing, Fig. 1, and to set the pouring gates and risers as indicated. This permits of a good washing action for the Thermit steel so that no molding material or slag that might be loose in the mold will be carried into one riser or the other. Fig. 2 shows a weld on an eight-wheel passenger engine made in this way and illustrates very clearly the arrangement of the pouring gate, heating gate and the two risers. Sometimes a third riser is advisable and as this often has to be placed in a position where it would be difficult to withdraw a wooden pattern, it can be provided for very easily by burying a sheet iron elbow in the mold. The Thermit steel will flow into this elbow, melting the pipe up to the level of the steel.

In the case of guide yoke repairs, it very often happens that the fracture runs in a horizontal direction and a Thermit weld is, therefore, made under very similar circumstances to a weld on

a vertical frame member. A simple way to obtain adequate washing action for the Thermit steel is to cut out the fracture so that the space cut out inclines to the vertical instead of running horizontally. This can almost always be done and the resulting weld will be as shown in Fig. 3.



SHOWING HOW BREAKS IN VERTICAL FRAMES SHOULD BE PREPARED FOR WELDING

In the case of welding light sections, such as an angle iron or light "T" section, care must be taken not to have the Thermit steel collar or reinforcement too heavy and also to see that the collar conforms to the shape of the piece being welded. Too often the collar is made so heavy that it concentrates too much Thermit steel around the part to be welded with the result that the metal on the edge of the weld is apt to slough away. Welds on such sections can easily be made with collars not more than 3 ins. wide by ½ in. thick, tapering to the edges. This, of course, depends on the thickness of the metal, and the above would apply to a metal from ¾ to 1 in. thick.

This question often comes up in the welding of such sections as guide yokes, driving wheel spokes, cross heads, and valve gear parts, because the welder more often than not has gained his experience in the welding of locomotive frames which are comparatively heavy, and is apt to have a tendency to follow that practice when called upon to weld parts that are not so heavy.

While cutting down on the collar is all right in the case of light and thin sections, it must be remembered that in the case of heavy sections such practice will not do, and it has often been noticed that Thermit welders, in an effort to reduce the amount of machining on a weld, will make the collar altogether too thin for safety. Sometimes they only do this on one side, which is worse still.

The Thermit steel collar should always be of uniform width and thickness on all sides in order to obtain uniform heating and therefore uniform results. It should always be borne in mind that the weld is the main object and the weld will not be perfect if the dimensions of the collar are varied on different sides.

## ENGLISH RESTRICTIONS ON ELECTRICAL PURCHASES

Applications to the British Ministry of Munitions for priority certificates to permit the purchase of motors and other electrical apparatus now have to be accompanied by a certificate from the chief engineer or manager of the public service undertaking concerned. This certificate is to state:

1. That adequate generating plant capacity is or is not available.

2. That no additional cost or material is involved in connecting the premises to the mains (including substation equipment, if any), or

3. Where expense is involved the material and apparatus to be provided and the cost thereof, and whether lead-covered cable is necessary or not. Where lead-covered cable is deemed necessary, the voltage of the current transmitted should be stated.

Applicants should, whenever possible, also obtain the written support of the Government department interested in their manufactures, and forward a copy of same.

The purpose is to reduce the demand for energy—other than that used for urgent war purposes—supplied by the public service undertakings and the time occupied in making inquiries.

New restrictions relating to electric converter plant have also been issued by the British Ministry of Munitions. Applications under this order are to be made to the director of electric power supply in the Ministry of Munitions.

## PAPER FROM SAWDUST NOW

At the Donside Paper Mills, Aberdeen, the success of the experiment in making paper from sawdust has now been practically demonstrated. The Aberdeen Evening Express has been in part printed on paper which contained a large percentage of sawdust. The experimental reels were in every respect satisfactory, and the Express is the first newspaper in the United Kingdom to have proved the practical utility of sawdust paper, the output of which promises to have a far-reaching effect on the paper scarcity problem. A hundred years ago experiments in paper-making from sawdust were made at a small mill in Bermondsey.

## CHATHAM GOING AHEAD

Despite the high cost of all kinds of building material, a great deal of construction work is going on in the city, as reflected in the statement governing building permits for May, just out, by Chief Pritchard. The total for May was $39,190, almost double the same period last year.

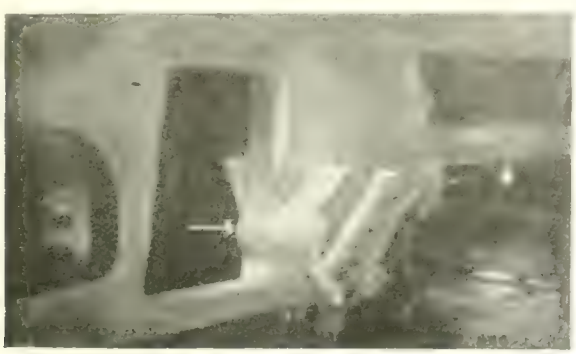


FIG. 2—WELD ON EIGHT-WHEEL PASSENGER ENGINE BROKEN IN VERTICAL FRAME MEMBER.

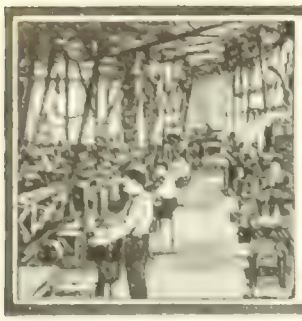
FIG. 3—THERMIT REPAIR OF A BROKEN GUIDE YOKE



# DEVELOPMENTS IN SHOP EQUIPMENT

*Manufacturers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

## MECHANICS' TOOL CASES

A wide assortment of tool cases for mechanics is manufactured by the Mechanics' Tool Case Mfg. Co., 271 Euclid Avenue, Toronto. The tool cases are of strong construction in [illegible] to which they are often subjected. The cases are made from well-seasoned lumber and have dovetailed joints, except in one style, which has lock corners.

The cases are made in a number of styles, closed or open top, and in mahogany, quarter-cut oak and selected bass wood covered with fabrikoid. Any style can be supplied in oak or covered. The highest grade case is made of mahogany, highly polished, with a removable front, which, when not in use, is slid under the bottom drawer. This case has an open top with seven drawers, and has a cylinder lock with plated trimmings. This case is made in three lengths, 16 in., 18 in., and 20 in. by 12¾ in. high and 9½ in. wide.

Another style is made of selected bass wood and covered with imitation leather. This case has a closed top and eight drawers, which have maple sides and mahogany fronts. The small drawers have sheet metal bottoms, while the larger ones are made of 3-ply veneer. This case is also made in three sizes, 16 in., 18 in., and 20 in. by 11½ in. high and 8½ in. wide. This case has plated trimmings and a removable front.

The quarter-cut oak case is made with open or closed top, and is nicely finished. The open style case has seven drawers and the closed style eight. The drawers are of the same construction as in the mahogany and imitation leather cases, except that they have oak fronts. The open top style has four trunk latches in addition to the lock, while both styles have removable fronts. The oak case is made in three sizes, 16 in., 18 in., and 20 in. long by 11½ in. high and 8½ in. wide. All the cases are nicely finished, and their general appearance considerably improved by the diamond [illegible] plates under each drawer knob.

These cases are intended primarily for tool makers and for anybody using fine tools, such as micrometers, verniers, gauges, etc. The drawers are made in various sizes, so that any particular tool can be kept separate. The open top style cases have a deep box on the top for larger tools. All the cases have a good lock and duplicate keys. The company manufactures these cases for the trade, but also sells direct to private consumers in towns where no dealers are located. These cases were originally made in Hamilton by Ira Embree, who formed the new company and moved the business to Toronto.

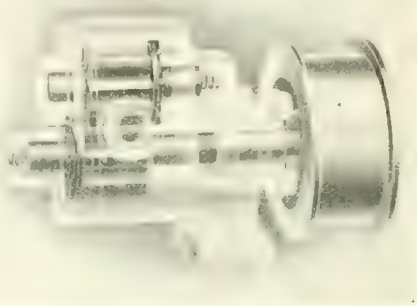
MECHANIC'S TOOL CASE.

## GEAR PUMP FOR CUTTING FLUIDS

According to tests made by the manufacturers, C. F. Roper and Co., Hopedale, Mass., the efficiency of a gear pump is far more dependent upon the endwise fit of the gears than upon the fit of the outside diameter. It was found that a looseness of .004 inch in the endwise fit of the gear would make the pump unable to start up under a suction head of three feet without priming, while .01 inch could be taken off the outside diameter of the gears without making this impossible. Furthermore, it is evident that as the outside diameter of the gear must be smaller than the pump housing in order that the gears may run at all, there can be but very little wear on the outside diameter in any event.

On the ends of the gears, however, which are made to fit as nearly as possible the housing, wear is certain to occur, because the space is so small that grit or chip entering the pump and getting into this space is ground around and cuts down the length of the gear until finally it is loose.

The Roco pump overcomes these difficulties by means of offset gears and spring compressed pistons on the gear ends. This construction makes any end



SKELTON VIEW OF CIRCULATING PUMP SHOWING END PISTONS ON GEAR MEMBERS.

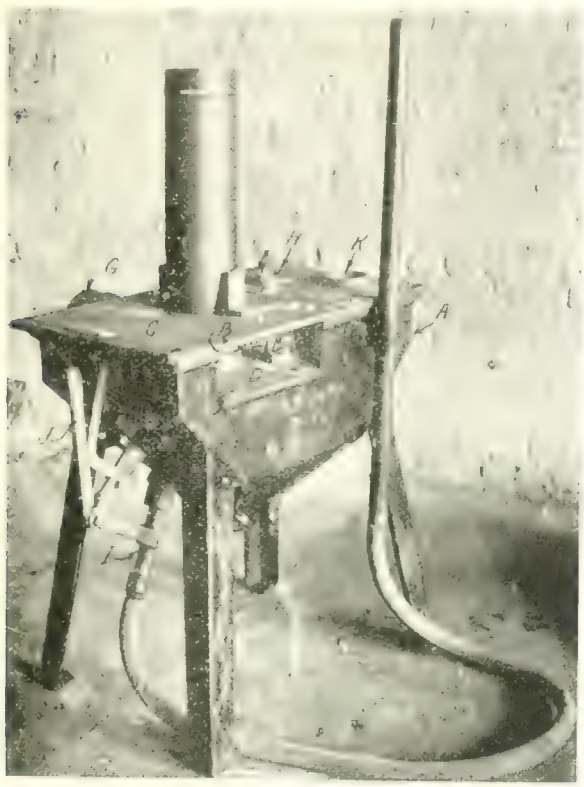
looseness impossible as any wear is immediately taken up.

This pump requires no by-pass or relief valve, either in the pump or in the piping, as the pistons operate to by-pass any fluid when the pressure in the delivery line is greater than that exerted by the spring controlling the piston.

## NEW SANDBLASTING MACHINE

FACILITIES for cleaning the interior of high explosive shells are essential in meeting the requirements of government specifications, and to insure a surface free from grease and other foreign matter that would prevent the adhesion of the protective coat of varnish. The accompanying illustration shows a machine designated by D. W. Richards for sandblasting the bore of the various sizes of shells. The box frame A is supported by means of the four legs so that the top of the machine is about 30 inches from the floor. The center of the top plate is bored out to receive the hub of the large bevel gear B, located directly below the plate C. The plate D, that is secured to the gap in the box frame, carries three brackets E, which in turn support three small bevel rollers F; these rollers are located 120 degrees apart and bear upon a turned surface just inside of the teeth on the large

bevel gear. The small roller shaft at the rear of the machine also carries a small bevel pinion for driving the large gear. This gear and likewise the shell, is revolved by the small pulley G secured to the small pinion shaft. The sand is placed in the box through the opening H and the air is delivered through the pipe and hose shown. The nozzle I can be moved in and out by the action of the bell-crank lever J. The exhaust air is allowed free egress through a pipe attached to the opening K. These machines are being made by the Montreal General Tool Company.



SAND BLASTING MACHINE

## HEAT TREATING PROCESS FOR SPADE CUTTERS

The loss in money, material and output due to breakage of shell-boring cutters of the double-edged or spade type has been a constant and hitherto unavoidable handicap to many munition makers. The use of high speed steel has been a necessity in order to get the output, but the very virtue of this steel which gave it its superiority as a cutting material reacted against it in the shape of cracks through the clamping holes induced and facilitated by the methods of hardening hitherto in use.

By a special process controlled by the Canadian B. K. Morton, Ltd., Montreal, it is now possible to provide a cutting edge of ample hardness to meet severest demands while retaining the central portion of the cutter in a tough condition so that breakages are completely overcome. The process is applicable to the full spade or double-edged cutter, and also to the single or half spade type.

## A SUBSTITUTE FOR BRASS

By Mark Meredith.

The very high price of copper, brass, zinc and tin resulting from the war has taxed the ingenuity of both men and nations to find substitutes. Many combinations of these have been made with steel, iron and other metals to bring down the cost, and there has been a considerable increase in the use of cast iron for bearings. This metal makes an excellent bearing if it is well fitted and has sufficient area, but once it begins to grip at any ill-fitted part, much mischief may be caused in a very short time.

Metal is far from being the only material for bearings. Various hard woods have been successfully used for the purpose, notably in the case of screw propeller shafts that have for many years been made of lignum vitae, which grows principally in the West Indian Islands, but increasing demands have rendered it so scarce that substitutes had to be sought for.

The Philippine Islands Islands are famous for the quality and variety of their hard woods, and of these the mancono is reported to be the best and most durable. The following is a comparison between lignum vitae and mancono:

Lignum vitae (guajacum officianale) is greenish brown and the sapwood is a bright yellowish color. Its specific gravity varies from 1.17 to 1.39. The grain is fine and the wood fibres small and exceedingly twisted, thus making it a very difficult wood to split.

Mancono (xanthostemon verdugonianus) has a brownish heartwood that turns purple when exposed to the air; the sapwood is narrow and of a pale reddish color. The wood weighs from 77 to 90 pounds per cubic foot or 44 per cent. heavier than water. Compared with teak it is just double the weight. Tests have been made of this timber that show it impervious to decay, being proof equally against the white ant and the teredo, or sea worm. An official test was made with it in the stern tube of a steam launch in constant use, and after seven months it was withdrawn and the commander of the naval station reported it to be quite equal to lignum vitae when used for the same purpose.

There seems to be an opening for mancono amongst ginning factories both as bearings for the shafting and for the connecting rods of gins. They might be [illegible] of a small circular saw and a revolving cutter. A comparison may be made of the friction of hardwood bearings with those of brass from the table published by Trautwine representing the co-efficients of moving friction of a smooth surface when kept perfectly lubricated: Wrought iron on brass lubricated with olive oil 0.078; wrought iron on elm 0.078. It is probable that mancono would have about the same friction co-efficient but would be more durable on account of its resemblance to lignum vitae.

The durability of wooden bearings depends to a great extent upon the smoothness of the metal in contact with them, and thus the metal should be carefully smoothed. In shafting an extra allowance of length might be made in view of the inferior hardness of the wood as compared with brass. With brass castings at such high prices it would be well worth the trouble to factory owners to experiment with wooden bearings, and begin with the hardwoods of the country that is nearest to them. India supplies a number of hardwoods, including babul and the various iron woods found in the jungles. It must not be forgotten that until the development of wheel-cutting in steel and iron, which is of comparatively recent date, power was transmitted through wheels with wooden teeth that rendered very good service, and even to-day there are millions of carts in the world with wooden axles carrying merchandise a long distance. Even the Japanese, who are already making and exporting electrical plant and instruments of precision, are still using machinery of wood to manufacture goods for export.

## YOUTH

YOUTH is not a time of life; it is a state of mine. It is not a matter of ripe cheeks, red lips and supple knees; it is a temper of the will, a quality of the imagination, a vigor of the emotions. It is the freshness of the deep springs of life. Youth means a temperamental predominence of courage over timidity, of the appetite for adventure over the love of ease. This often exists in a man of fifty more than a boy of twenty. Nobody grows old by merely living a number of years. People grow old by deserting their ideals. Years wrinkle the skin, but to give up enthusiasm wrinkles the soul. Worry, doubt, self-distrust, fear and despair—these are the long, long years that bow the heart and turn the greening spirit back to dust.

Whether sixty or sixteen, there is in every human being's heart the lure of wonder, the sweet amazement of the stars and at star-like things and thoughts, the undaunted challenge of events, the unfailing childlike appetite for what next, and the joy of the game of living.—"American Iron and Steel Institute Bulletin."

**Arthur Balfour and Co.** are now issuing a monthly stock list covering their various lines of carbon and high speed steels.

## BARRING OF NON-ESSENTIALS BEGINS

THE first step has been taken by the Federal Government in its effort to correct the trade balance by means of import prohibitions. Luxury imports, as war-time non-essentials are termed, have reached an annual total of $70,000,000.

The classes of good which are affected are either perishable, pertain to personal pleasure and sport, or are non-conducive to production, the latter category including such items as paintings, jewelery and marble.

The entire situation is based on the necessity of keeping out that which we can do without, and producing as much as possible of that which we need, with a view to reducing the amount of trade at present in favor of the United States.

At least 75 per cent of the goods banned are obtained from across the line, and the measure is accepted by the United States Government in the spirit in which it has been enacted.

The stimulation of several home made lines should result forthwith, provided raw material is available, and while it may devolve on the War Trade Board at Ottawa to exert influence in this respect, the difference between raw materials and finished product should be great enough to insure some considerable initial influence on the adverse trade balance.

## HUMAN NATURE AND PRODUCTION

MAKING a study of the individual characteristics of different workmen has often been a valuable factor in developing and maintaining greater plant efficiency. Among the many duties of the factory superintendent or foreman—and one that might be considered as of small consequence by the unobservant—is that of cultivating the personal touch with those of his workmen or associates whose co-operation is essential for effective production. One of the very important features in connection with shell making is that of inspection, particularly that involving the Government examinations. In many instances these men perform their duties under certain fixed rules and instructions from higher officials, so that tactful judgment on the part of the under-inspectors is frequently an absent quality. However, experience has been a remarkable teacher in the education of those now engaged in this work, and differences between plant officials and Government inspectors—that in the early days were often greatly magnified—have almost been eliminated, so that in the place of antagonism and spasmodic disorganization, the best co-ordination now manifest

The superintendent of one plant was successful in overcoming the prejudices of different inspectors by the adoption of the following plan: His experience in various shops and with different inspectors led him to believe that nearly every one paid more than ordinary attention to the inspection of some particular portion of the shell; one man would be very strict on the wave and groove, another on the bore and inside profile, and still another on the outside profile, base plate, etc. After finding the inspector's special "bug," as he termed it, the superintendent set to work to humor the former's vanity, giving instructions to the foreman in charge of the particular operation that extra precaution be exercised by the men on these machines in producing work that would meet the personal requirements of the inspector.

In commenting on this particular feature the superintendent said: "While it is highly desirable that every detail in connection with shell making should receive the closest supervision, it is no doubt true that the study of the traits of those responsible for the acceptance of the work is a factor not to be overlooked by the different plant executives."

## LEGITIMATE MANUFACTURE SHOULD BE MAINTAINED IF POSSIBLE

THOMAS A. Edison is of the opinion that the way to meet the present situation is not by curtailing the manufacture of what are termed non-essential commodities but by increasing production. In a recent signed statement to a convention of phonograph dealers in New York he said:

"No legitimate industry is non-essential except as it interferes with the conduct of the war, and then only to the extent to which it interferes. No statistician can prepare figures that can be accepted safely as a guide to the curtailment that should occur in the manufacture of the so-called non-essentials

"What we need to do is to speed up. It is not a question of what we must not do, but a question of what we must do. We must win the war. We must provide all the arms, ammunitions, ordnance, airplanes, and equipment that can be transferred to Europe, and we must build ships as rapidly as possible.

"We must make all the other goods that we can possibly make. We must keep on creating new wealth. We must keep our manufacturing organization in good running order. We must continue to go after foreign trade, and we must prepare ourselves for the intense competition for foreign markets that will come after the war."

Mr. Edison's idea seems to be that in this time of stress it is not fitting that industries should be torn up root and branch. He recognizes the need for production of war materials. But he does not think that the manufacturing organization should be crippled in certain lines.

The great inventor would make two blades of grass grow where formerly one grew. Production of certain commodities can be kept up even when the working staffs are reduced to provide for the necessary war work. Production of war materials on the other hand should be speeded up. This is sound business sense.

In connection with the work being carried on by the Council it is proposed to establish a Central Research Institute and that in connection with this project the government will be asked for a grant of about $500,000. Of this amount about $100,000 will be in the shape of salaries or an annual obligation while the remainder will represent capital expenditure for the installation of the required apparatus and equipment.

Another phase of the problem has to do with educational facilities and plans are being considered for the establishment of new branches of activity in connection with the big universities.

# THE MAN WHO STARTED FUSE MAKING IN CANADA

**Arthur Kirby Had a Wide Experience in England Before Coming to Canada**

THERE is no particular novelty or secrecy connected with the making of fuses in Canada now. There was a time, though, when an intimate knowledge of the delicate operation was in possession of practically one man in this section. That man was Arthur Kirby. He had learned the business thoroughly in the big munitions plants of England. At that time though there was not the element of urgency in the situation that developed when Canadian factories first turned to the making of fuses.

There were many deliberations, long and serious, before the work was undertaken in Canada. It was a new venture, more complicated and less known than the forging or machining of shells, and on this account, and the lack of expert help to swing the business, delay was long.

Arthur Kirby, now of the Russell Motor Car Co., knew the fuse business—knew it thoroughly. He had served for many years in the greatest plants in England, and had been in Vickers, Son & Maxim when the first orders were undertaken on the No. 80 fuse for the British Government. The No. 80 is essentially and originally a German time fuse, changed and improved to suit the purpose and style of the British guns.

Mr. Kirby started to serve his apprenticeship at the age of 15 with Kynoch, Ltd., at Birmingham, working in all departments, and finishing as an expert tool maker. In all he remained in that immense plant for eleven years. At that time between eight and ten thousand people were employed there. His father was an employee of the same shop as manager of the sporting cartridges department.

Leaving this firm, Mr. Kirby went to the great Vickers, Son & Maxim plant in 1905. At that time the first government order was given for the No. 80 fuse, and he was placed in charge of the fuse department. Making the No. 80 fuse at the Vickers, Son & Maxim plant was new work, the design being largely an adaptation of the German usage. New machinery, and all the tooling had to be designed, and it was here that Mr. Kirby mastered the fuse business for the great British munitions shop, little thinking of the use to which he would be called to put his training later on.

### Comes to Canada

Leaving the Old Country some six years later he came to Canada, direct to Toronto, going with the Canadian Fairbanks-Morse as a tool maker. Later he joined the staff of the Architectural Bronze & Iron Co.

With the declaration of war, and the commencement of munitions making here, the question was asked "and what can be done for fuses?" Mr. Kirby knew how to make fuses, knew the machinery and equipment necessary for their production, and it was not long before representatives of the old Shell Committee got in touch with him. Even before the arrival of any prints or drawings from the Old Country, Mr. Kirby had sketched out the requirements, and took charge of the work when the Russell Motor Car Co. decided to start the manufacture of their first order [illegible]

### Got Splendid Results

The venture was a success in every way. "The matter of sufficient help was something that bothered us at first," remarked Mr. Kirby, but the introduction of female labor was the solution for that. It was something new in this country, but in the large munition plants of England female labor is largely relied upon. There were in Toronto a number of English women who had worked at fuse making, and at the very outset we got splendid assistance from these people. Of course the Canadian girls came in later, and they gave good service too, although they do not appreciate shop discipline and the need of it as the women from the Old Land do.

"As a matter of fact," concluded Mr. Kirby, "there is a very serious shortage of good mechanics in Canada right now. Even in the past this country has never been noted for its number of first-class mechanical men. Too many of them never get past the handy-man stage."

Mr. Kirby is still with the Russell Motor Car Co., Ltd., in charge of the vocational school for returned soldiers, which is being operated by the company on Adelaide St. west.

## A Word for the Candle

The Hydro lights were off last night, and there was the usual scramble for candles, etc.—News item.

It does beat all how some folks make a fuss and grit their teeth, and make themselves look just as though they had a quart of grief—why, good land sakes it ain't no cause to worry nor to fret, nor yet to get your system in a state that's overhet.

What if the 'lectric lamps go out and leave things on the blink, it gives a chance to contemplate, to meditate and think.

It makes your sister raise her nose from off some fancy work, and it makes paw pause a bit when he's readin' 'bout the Turk. And then they light a candlestick, it sputters out a gleam, and somehow it's a restful light, though not a head of steam.

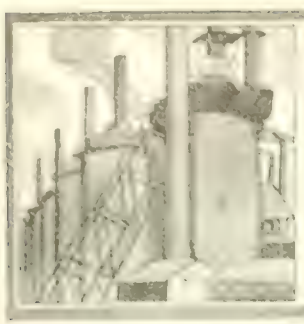
Why, our grand-dads and mothers too, they used a light like that, and though perhaps they didn't get things fresh right off the bat—they used to sit when day was done to rest their weary bones, and they didn't have no 'lectric lamps to 'luminate their homes.

But by the candle's little glow they'd talk of the hereafter, while fragrant pipes would build a haze to circle near the rafter. And in those hours of sweet content, oh let their praise be sung, their every corner got a rest, their liver and their lung. But folks don't want no candles now, nor evenings that be dim—they want the 'lectric searchlights on to keep them in the swim.

They aint content to have the sun a-blazin' far away, but they want to spoil the twilight by makin' it like day.

Let's have a candle now and then, of the 'lectric lamps be rid, and sit and meditate at night like our grandfathers did.—Ark.

and steel industry of United States was that the market had been engaged in a wild runaway. Prices at which Canadian jobbers months ago stocked up at United States mills testify to that fact. While the producers were promised very large profits temporarily, it would not have been good business for them to have the run of the market for any length of time. Natural laws of trade, that usually make for equalized conditions, were altogether suspended. No class of manufacturers can indefinitely prosper in conditions that are altogether unsound economically.



# MARKET DEVELOPMENTS

## A Launching in Every Yard on the Fourth

### Unique Way in Which U.S. Plans to Celebrate National Birthday—Firms Having Made Success of Canadian and British Business Get Preference on New American Orders

THERE are few weeks passing now but are marked by a spectacular price jump. Sometimes it is in the realm of iron or steel, again in the values of chemicals. But without fail the price jump takes place. This week staybolt iron has furnished the feature. It has advanced $40 per ton. In fact it is almost double the price at which sales could be made two months ago. It is used in good boiler work and is much needed now.

Canadian firms continue to take on new orders for munitions. Those that had the greatest degree of success with the Canadian and British orders are receiving a preference on the business which the American government may have to place in this country. There is also a revival of the rumor about the making of airplane bombs in Canada. Possibly the idea is that reject shells will be used for this class of work. They will not stand gun operation, so would be fitted with a tail piece to keep the nose pointed to the ground and would explode upon striking any object. Nothing has been done in this matter yet, and rejects are not being held for such a purpose, but are passing as formerly back to the furnaces.

There is bound to be a unique Fourth of July celebration in many parts of United States this year, especially along the coasts. It is planned to launch a ship from every yard now working on government orders on that day. And in more than one way United States is showing the serious way in which it is approaching war business. There are many mills in the Western States that cannot turn over to the work of producing steel or pig iron of a quality that can be used in war work. These places are simply being closed down and the basic materials formerly used by them are passing over to the shops turning out government requirements.

Jobbers in United States are hoping for better times ahead, and the trade in Canada is wondering how they will make out. Restrictions on buying for warehousing purposes were put on with the idea of preventing the hoarding of material, but the jobbers point out now that a certified inventory and sale sheet would serve this purpose. Especially where ship building is going on it is desirable that warehouses should be fairly well supplied with standard sizes to make good the rejects that the builders may get in their deliveries from the mills, and which must be quickly replaced to avoid delay.

Supply prices for machine tools are the same, no changes having been noticed this week. Business remains brisk, and orders placed for shops handling new munitions orders would indicate that it will remain so for some time

## FREIGHT CHANGES MAY AFFECT THE PRICE OF MACHINE TOOLS

Special to CANADIAN MACHINERY.

MONTREAL, June 19.—The characteristic feature of present conditions is the ever-increasing emphasis placed upon essential activities. The prosecution of the war has now become of such importance that the reduction of unnecessary enterprise has almost reached the point of practical isolation. That this condition will become additionally pronounced is recognized by many, and the entire elimination of non-essentials may only be a question of time. The present national registration may be a vital factor to this end. Steel for ship construction is coming forward in good volume, but some makers of shells are complaining of inadequate supply. Machine tool interests are all active but the supply is insufficient to meet demands

**Steel**

Present industrial activity is almost entirely operated on a war basis and everything of any magnitude is virtually controlled by the government and the War Trade Board. Dealers here are looking forward with considerable interest to developments in the States, as the coming advance in freight rates on American roads has created much excitement across the line. It is anticipated throughout the trade in this district that some similar action may be carried out in Canada in the near future, and as negotiations for government control of certain railroads show further progress a higher rate is not only likely, but within the bounds of probability. Speaking on the possibilities of a stronger steel market as a result of freight advances, dealers here do not anticipate anything along these lines in the immediate future, as present regulations would offset such a move, but should it develop that considerable volume of steel could be diverted to ordinary commercial enterprise, the situation would become one where steel prices may be affected.

Recent action on the part of the American War Board has given renewed hope to those consumers coming under the classification of non-essential industries. When the government requirements and preferred demands are amply supplied the surplus production may be available for other purposes, but may only be distributed to the trade on the written approval of the board. This new ruling to some extent will release the producer from previous responsibilities. However, until the new regulations are effective for some little time uncertainty will still prevail, as present needs of first and second choice are not sufficiently known to predict what volume of present production may be diverted to ordinary commercial enterprise. With war requirements of such an abnormal character, domestic activity can expect but little encouragement.

Price quotations are very firm and

the [illegible] relatively quiet

### Metals

Interest is being displayed over the increased activity in several of the metals. The coming change in transportation charges may serve as an argument for better prices and there is a possibility that some revision may be made respecting fixed prices and advances may result where the market is an open one. Copper is firm but producers are bidding for a higher price. Tin is easing on better supply. Spelter, lead and [illegible] strength of improved demands. Aluminum is steady and firm.

**Copper.**—Renewed agitation for a higher price on copper has arisen as a result of the announcement of the new advance in freight rates. It is more than likely that negotiations will be carried out with the object of coming to an agreement in this connection, as the arguments of the producers are more convincing than those of a few weeks back. The market here is not disturbed by these developments but dealers are watching the American situation for interesting developments. Local prices are unchanged on a quiet but steady market; quotations are firm at 29c and 30c per pound.

**Tin.**—The situation here has taken on a less nervous tone, following the report of an easier market in London, and the fact that shipping permits are more readily obtainable. The situation in New York is still acute but relief is in sight with the possibility of better supply. Prices there are still nominal in character on a basis of 90c per pound. Dealers here are inclined to think that the most acute stage is over, but the return to anything like normal will be quite gradual. The market here is still strong but with an easier tendency. Quotations of $1.25 shows a decline of 5c per pound. During the past week as high as $1.40 was asked in 100 pound lots.

### Machine Tools and Supplies

Heavy requirements still exist for machine tool equipment and facilities of the builders are invariably inadequate to the demands; in consequence manufacturers are unable to promise machinery for definite delivery. In order to expedite operations certain shell makers here are having their tools made in several local shops. Machines coming in from the States are very difficult to acquire as the demand on the home market is abnormally heavy. Dealers here would not be surprised to announce advances on machine tools in a few weeks owing to the coming change in American freight rates. Shipbuilders are consistent buyers of pneumatic tools. Shipments of the smaller class of tools are more regular.

### Scrap Quiet

The old material situation is practically a reflection of other activities where operations are conducted on a basis of government regulations. Dealers here report a quiet week with the bulk of the business being done on a basis of immediate requirements. Machinery scrap is still in good demand but the price tendency is weaker. Tin scraps are active but the undertone is for easier prices. Lead scrap has advanced following the stronger position of the ingot metal. Local dealers are asking 5½c for tea lead, a ½c rise over last week.

## POINTS IN WEEK'S MARKETING NOTES

The price of staybolt iron has jumped $40 per ton this week. In fact it has almost doubled in value during the last two months.

Canadian steel jobbers are trying to get some relief at American jobbers secure recognition from the war board.

Talk is heard of making aerial bombs from reject shells, fitting them with tail pieces to keep the nose toward the ground. So far nothing has been done toward this as all rejects simply pass on to the furnaces again.

Even with every mill ton turning directly to the order of the war board there is not enough steel for war work, and none at all for commercial business.

Shortage of labor is going to interfere with building of the plate mill under government orders at Sydney, N.S.

It is planned to celebrate the Fourth of July this year by launching a vessel from every shipbuilding yard in the United States.

Mills are wondering what to do with any "off-heat" ingots as they will find it too expensive to hold them or reheat. They are bound to turn everything to government direction.

A large number of mills in the Western States are closing because they cannot supply the sort of steel needed for war work.

U.S. fuel administrator warns that there will probably be a fuel shortage this winter in Canada as well as United States.

New shell orders in Canada are going to the shops that made the most satisfactory showing on Canadian and British business.

Transportation conditions are so serious in the United States that they are interfering with the production of munitions.

## PRICE JUMPING IS OF THE $40 NATURE

### At Least That's the Figure That Is Being Put on Staybolt Iron

TORONTO.—Equipment for new shell shops is being asked for by Canadian firms who have taken on new war business. In some cases the number of hangers, etc., that are included in the lists would indicate beyond doubt that extensive business is planned. It is likely that the large calibre business from Washington will come to Canada. CANADIAN MACHINERY has it on very good authority that the American officials are well pleased with the way in which Canadian contractors are going about it to live up to their delivery promises. In this regard it is stated that the performance by factories on this side of the line is much more satisfactory than records made in United States. Canadian shops that made the best showing in handling the Canadian and British work are being given the preference in American orders.

Steel jobbers are wondering if it is possible that they shall secure some measure of relief from the anti-warehousing rules that were laid down by the department some six weeks ago, and which have been enforced strictly ever since. Action is being taken across the line in this direction, and it is possible that the same may happen here.

Prices came up again to-day for one line, viz., Staybolt iron. In these two days of price-jumping there has to be quite a gap opened up from the old price before the amount is noticeable. Staybolt iron went up a clean $40 per ton—in fact the price of this line has just about doubled in the last two months, it being much sought for boiler work.

The large order for 3½-inch tubes, which was referred to in these columns a week or so ago, has passed the War Board. Delivery will be made very shortly. There was some speculation as to whether the order would receive consideration as it could not be classed as war work.

There has been a revival of the talk about using reject shells for the making of air bombs, the idea being to rig them up with a tail piece that would keep the nose pointed toward the ground, but nothing definite could be learned concerning this.

### Prices Are Increasing

Dealers in steel goods are wondering if there is going to be any relief for them from the order that forbids the warehousing of plate, and other lines mentioned under the orders from Ottawa about six weeks ago. They are watching the steps that are being taken to secure some form of recognition for jobbers in United States, and if success is met there they see no reason why it should not have some influence on the situation here, as they are practically distributors for the same mills as their colleagues in the States. The idea behind the rules

in the market this week. That is stay- per hundred, or an increase equal to $40 increases have been so rapid that it is doubtful if dealers will clear themselves are.

mentioned that an order had been sent forward from a Toronto house for a large number of 18-ft. boiler tubes of the 3½-inch sort. To-day word was received that the order had received recognition at Ottawa. There is no improvement in the tube situation regarding the two-inch size, which are in such urgent de promises of any better supplies in regard to steel for commercial purposes, in fact they are discouraging the placing of orders, knowing that they have mighty small chances now of being passed.

### Scarce But What of It?

Tin is scarce. There is nothing new in that. In fact it has been stated so often in market reports that people are beginning to wonder if it's true. The element of price comes in to emphasize the certainty of the scarcity as it is over five times the old price. But dealers stated to-day that they did not know of any concern that was shut off for the want of tin, although there was very little of it in the country.

Trade in all lines of non-ferrous metals is good. Prices can hardly be stated to be a fair indication of the trading value in certain items. For instance bids were raised in New York for spot tin from 91 to 93 cents, but there was not a pound traded. Canadian dealers point out that there has been no confirmation yet about the fixed United States price for copper. This is supposed to be 23½c per pound. As a matter of fact there has been no official announcement concerning the matter. It is urged that part of the output should be allowed to pass into open trading as in the time before prices were fixed, but such a state would be undesirable, as in an abnormal market regulation is necessary to give stability to the trading.

Locally metal prices are unchanged except for lead, which advances 50c per hundred pounds.

### More War Business

American orders are still coming to Canada. More have been placed for the 155 mm. shells. We are informed that on the placing of this business the Canadian shops which made the best showing on British and Canadian business are likely to receive the preference in the placing of the new business. As a matter of fact this rule has been largely followed, and will still be adhered to. Canadian munition firms have lived up to their delivery promises and have made a good name for the shops on this side of the line.

There may be orders for shells larger than the 155 type, although the amount of this business placed so far is not very great. The rumor is also around concerning the making of airplane bombs. It has been suggested several times that reject shells from Canadian plants should be used for this purpose. At present all such are passed back to the furnaces, nor are they being held for any such object as airplane bombs.

### Near Stagnation

There is nothing moving in scrap metals. "A year ago," stated one Toronto dealer to-day, "we wouldn't go out of our way to secure a hundred tons of scrap iron, but to-day we will go far afield if we hear of half that amount offering." Prices do not change at all, and there is only a very nominal amount of business moving.

### In Supplies

Supplies for machine shops are in good demand, and prices and discounts and additions to lists remain much the same. There is a certain amount of sympathy between values, and some of the articles that do not enter into the war furnishings are feeling the trend of prices. For instance certain lines of valves are off the old lists now, pending an upward revision of prices. It may cost more to produce the goods now, but as a matter of fact nearly all the supply houses have a good number of the valves on hand, secured at old prices.

## RECORDS GIVEN ABOUT DRIVING RIVETS ARE VERY MISLEADING

Some of the riveting records that are being made and published at present are very confusing. Figures have now got to the stage where they reach to the thousands per day, some as high as 12,000. When one reads of that number of rivets being flattened out in a single day the record of 1,200 in a day looks small, and there must be something to explain the discrepancy, otherwise it would appear that there were a great deal more efficiency in one class of yards than in others.

Take for instance the case of John Moir, a workman in the yard of Workman and Clark, Belfast, who is credited with a score of 11,209 in nine hours. It is stated that this work was done by a hydraulic hammer, and "driven in floors." This explains much, and shows for a certainty that there is no fairness in comparing that performance with the work done by the ordinary air-gun used by the riveters on the work in Canadian yards. The hydraulic-driven rivets are not really driven at all, but pressed into by the hydraulic ram principle, which can be made to give hundreds of tons' pressure. It is only on a few certain parts that this method can be used, for the piece to be riveted has to be of such a size and shape as will fit between the horns of the "bull riveter," as it called in the shops.

Further, the rivets in the floors would not have to be watertight, and probably a full head was not required, but just the end of the rivet 'burred' over to hold the pieces together.

Rivets in the sides of boats and ninety per cent. of the field or 'erection' rivets must be driven down by the air hammer and forced to completely fill the holes and head formed by hundreds of quick blows. The riveting gun must be held on the rivet for sufficient length of time to allow the same to cool somewhat, or it would shrink away from the metal and be like a loose bolt. That is why no such a speed as mentioned above is possible on ordinary work with the standard equipment for driving same.

The record mentioned is no record of riveting at all. It is a record of a machine which is practically automatic. It is not riveting in the full sense of the word as the boilermaker understands it, any more than the number of nails a special machine could drive in a box factory could be said to be a carpenter's record.

## PLAIN TALK ON COAL SITUATION

**Special to CANADIAN MACHINERY.**

### Says Western Canadian Mines Must Increase the Movement at Once

MONTREAL.—Women freezing in the hearts of Canadian western cities and towns, families deserting their houses to go and huddle in cramped quarters with those who happen to have a little coal, closed schools, office buildings, and even hospitals, and possible epidemics of pneumonia and influenza, are foreshadowed in a statement issued this morning by the Canadian Railway War Board.

"This board cannot possibly exaggerate the gravity of the Western fuel situation," said Secretary W. M. Neal. "Only the seriousness of the situation prompts the board to issue what may be termed an alarming statement.

"The movement of coal from the Western Canadian mines to the consumers in the West must increase, and increase at once, if the people of the prairie are to have means of keeping warm next winter. There is the very highest authority for stating that they cannot and should not rely for one moment on the hope of obtaining the usual supply of anthracite coal from the East."

---

Baling Iron.—A New South Wales company requiring quantities of baling iron invites correspondence from interested firms in Canada who will supply samples and quotations as per particulars appearing in report from Canadian commercial agent at Sydney in this issue.

# SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

### PIG IRON

| | |
|---|---|
| Grey forge, Pittsburgh | $32 75 |

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5, 6 and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

# EVERY YARD IN U. S. TO LAUNCH A SHIP IN CELEBRATION OF FOURTH

Special to CANADIAN MACHINERY.

manufacturers desire. The War Trade Board has given the most positive proof of this in an order issued this week which prohibits the placing of further war orders in the eastern section of the country. [illegible] War Trade Board the action is taken solely for the purpose of relieving conditions in transportation. Up to this time the greatest part of the war work has been done in the Eastern States, particularly in the Atlantic coast States. This has resulted in a general freight congestion of raw material and finished products. The War Trade Board is now making efforts to divert this business to the Western States and to make it possible to clear up some of the freight congestion in the East.

The order recently issued by the Railroad Administration which calls for cash payment on all freight shipments has been postponed until August 1, in order to give manufacturers an opportunity to adjust their business so that they may meet the new demands.

### Are in Agreement

Manufacturers in the United States have been informed through the War Trade Board of the action of the Canadian War Trade Board in restricting the exportation of platinum, caustic soda, soda ash, Douglas fir ,and other war products. In very few instances have any manufacturers in the United States been dependent upon Canadian sources for these materials, but the War Trade Board and the Canadian War Mission are in an agreement whereby they will secure licenses for exportation from Canada for any of the needed materials if it is shown that war work would be vitally injured by the inability to secure the product from Canadian sources. It is possible that there may be an agreement which would in effect pool the resources of raw materials held in Canada and in the United States, but this is so indefinite at the present writing that it is hardly more than a conjecture.

### The Blow Falls Hard

Reports have begun to reach the War Trade Board of the effect of the recent order issued forbidding steel plants to manufacture steel for other than war purposes until all of the steel wants of the United States and the Allies have been filled. According to one report coming from the middle West more than two hundred steel plants have been forced to close down because of their inability to furnish the sort of steel needed for war work, their plants being adapted to special manufacture for non-war purposes. Members of the War Trade Board are very firm in their belief, however, that the order will work out to a fair advantage to all steel manufacturers and will result in such a concentration of steel supplies that within a short time it will be possible for some of the factories using steel for non-war purposes to resume their work.

### A Poor Outlook

The Fuel Administration has come out with a frank statement this week to the effect that there will be a coal shortage this winter in the United States and in Canada, in so far as Canada depends upon the United States for her supplies of coal. The estimates which have been made up to this time show that there is a possibility of some fifty millions of tons of bituminous coal needed which will not be available. Production in the United States during the past year has been increased materially, but consumption has increased far faster than production. The only possible remedy which the Fuel Administration offers is economy, and all users of bituminous and anthracite coal have been ordered to use the strictest economy in their coal consumption lest they suffer from serious shortage when the winter months come.

### Cutting Supplies

An important step taken by the Fuel Administration has been to order the cutting of the coal supplies furnished factories for the manufacture of pleasure cars 75 per cent. This step, coupled with the proposed heavy tax upon pleasure cars, is already being felt to a considerable degree by the manufacturers of automobiles in the United States.

### A Great Fourth

The United States Shipping Board has authorized the construction of five additional shipyards for the construction of concrete vessels. Already contracts have been let for forty-one of these vessels. The tests which have been made show that concrete vessels can compete with wooden and steel vessels and the estimated cost per ton is far below that of the steel and wooden ships.

July Fourth will be made a day of special effort in shipbuilding in the United States. It is planned to have a ship launched on that day in every shipyard in the United States.

The Ordnance Department of the War Department has announced that since the United States declared war there have been 1,568,661 rifles manufactured in this country.

# SHORTAGE OF LABOR MAKES THE BUILDING OF PLATE MILL HARDER

Special to CANADIAN MACHINERY.

SYDNEY, N.S., June 19.—The decision of the Royal Commission on the questions connected with wages which have for some time been an issue between the various steel companies and their employees has been announced. The commission has recommended an increase in the wages of the lower paid men, at New Glasgow, Sydney Mines and at the Sydney Steelworks. The minimum rate for day labor is raised from 24 cents per hour to 27½ cents, and a graded system of increases is recommended on a lessening scale ceasing at the men who receive from 30 to 32 cents per hour. Above this figure no increases are recommended. The decision of the commission is not acceptable to the higher paid men, and there are some indications of trouble. At New Glasgow the men ceased work on the 14th June, but it is not thought the trouble will be of long duration. Great stress was laid by the workmen's representatives in placing their case before the commission on the necessity for increasing the wages of the lower paid men, and the commission's decision was doubtless guided by a desire to adjust wages where the necessity was the greatest.

The reconstructed No. 1 blast furnace of the Dominion Iron & Steel Company is in process of heating up preparatory to being put into blast. The date when this will be done is largely dependent upon the date at which coke from the new ovens will be available. The housing is now being stripped from the new ovens, and it is expected they may be in operation by the beginning of August.

### New Plate Mill

Work on clearing the site of the new plate mill is now proceeding at Sydney, and the officials of the company are actively engaged on the plans of the mill layout. As the new mill is the first of its kind in Canada a good many problems have to be worked out, and the present time is more than ordinarily unfavorable towards quick construction because of the difficulty of obtaining delivery of materials, and the shortage of labor. The already inadequate number of workmen available for construction labor has been latterly decreased by the calling of young men for military service, and it is difficult to see how the work of constructing the mill can proceed as rapidly as might be desired, unless the Government itself can furnish a labor supply.

The location of a shipbuilding plant at Halifax appears to be definitely decided upon by the Government, and in a recent visit to Sydney Mr. Carvell has announced that while Sydney is destined to become more and more the centre of iron and steel manufacture it is not considered to be the best location for a dry-dock and shipbuilding plant. As between Sydney and Halifax at the present juncture Mr. Carvell's pronouncement is probably a correct one, but doubtless some day we shall see shipbilding plants both at Halifax and at Sydney—or it may be Louisburg. Nothing can ever

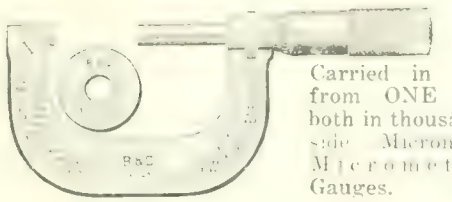
SALES SUPPLY DEPARTMENT SERVICE

## Machine Shop Superintendents, Tool Makers, Mechanics and Purchasing Agents

We are in a splendid position to supply you with every requirement in the tool line

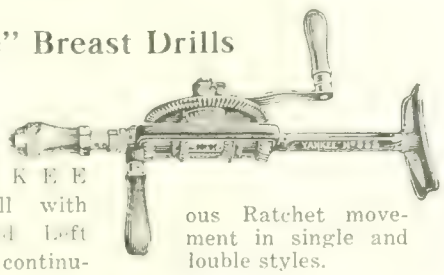
### MICROMETERS



Carried in stock sizes from ONE INCH up, both in thousands and Inside Micrometers and Micrometer Depth Gauges.

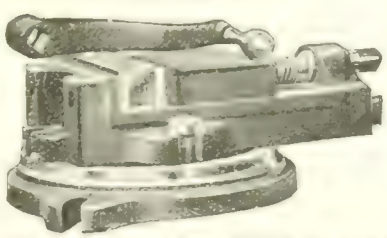
### "Yankee" Breast Drills

in stock at all times. We have the YANKEE Breast Drill with Right and Left Hand and continuous Ratchet movement in single and double styles.



### "Universal" Combination Pliers

Forged of High Grade Tool Steel perfectly tempered and carefully machined. Consists of Screw Driver, Reamer, Flat Nose Plier, Pipe Wrench, Wire Cutter, etc.

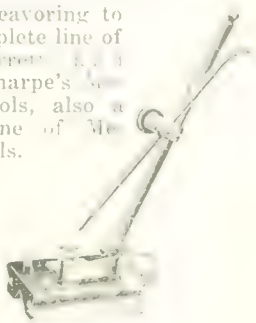


### "Williams" Combined Stationary and Swivel Milling Machine Vise, with removable jaws

Depth of Jaw 1⅝". Width of jaw 5". Vise opens 3". Weight 45 lbs. List price, $25.00

### MECHANICS TOOLS

We are endeavoring to carry a complete line of both Starrett and Brown & Sharpe's Mechanics' Tools, also a complete line of Mechanics' Tools.



### "Yankee" Screw Drivers

they are strong, durable, well-balanced tools. The fastening of blade and handle is such that they cannot be loosened in use, or even usual abuse.

### "Yankee" Hand Drills

These Tools are built mechanically on lines of a Tool rather than a piece of Hardware. They are strong and substantially built for hard work and durability.

### Trahern Pumps

For Air, Oils and Gasoline engines. The most RELIABLE Pump on the market. REASONABLE Price. The Pump with a reputation behind it. We have them right in stock.

shadow even the proximity of the coal-fields and the great steel plants on Sydday.

The production of coal in Nova Scotia, considering the drain on the labor supply to the Military Service Act, is keeping up fairly well, at the reduced level of the past few months. There is, however, not the slightest possibility that any Nova Scotian coal will go up the St. Lawrence this summer, except the most negligible quantity. The shortage of coal production is to-day overshadowed by the lack of ships to transport the

# HENRY FORD TO BUILD NEW TRACTOR PLANT

Special to CANADIAN MACHINERY.

**Steady Flow of Orders Going Out For All Branches of Machinery**

NEW YORK, June 19.—Great activity continues throughout all branches of the machinery industry. There is a steady flow of orders for cranes and fabricating machinery from shipbuilders and many additional purchases of shop equipment have been made by shell manufacturers and other manufacturers of war munitions in the last week. Railroads have also put out more enquiries for repair shop equipment and other lists are being prepared.

The Symington interests, which are already manufacturing guns and shells for the Government at Rochester, N.Y., are preparing to build a new plant at Chicago in connection with some local interests, to cost $6,500,000 and to have a capacity of 10,000 shells a day. Inquiries for machinery for the new plant have already gone out to dealers and to manufacturers. Other inquiries for shop equipment have come from the Motor Products Co., of Detroit, which is manufacturing 155 mm. shells, and from the Templar Motor Corporation of Cleveland, which is expecting a large shell contract from the Government. The Liberty Ordnance plant of the American Can Co., Bridgeport, Conn., has bought a number of new tools. The Mead Morrison Co., East Boston, has taken a contract for gun sights for which its shops are already well equipped and several of the electric companies are placing shop equipment to execute Government orders.

Shipbuilders have received bids this week on 200 cranes and 100 machine tools for two new yards to be constructed at once, one at Alameda, Cal., and the other in the vicinity of New York. It is understood that some of the orders for cranes have already been placed and contracts for punches, shears and rolls are expected to be closed in the next ten days. The American International Shipbuilding Corporation, Philadelphia, the Staten Island Shipbuilding Co., New York, the American Shipbuilding Co., Cleveland, and the Toledo Shipbuilding Co., of Toledo, Ohio., have purchased fabricating equipment, while the Foundation Co., which is to build a new plant at New Orleans, is also in the market for cranes and other machinery for plate and angle shops. It is estimated that orders from ship yards alone will call for the expenditure of $10,000,000 this month.

Manufacturers of tractors are constantly expanding their facilities and heavy purchases of machinery will be necessary. Henry Ford & Son, who will build a tractor plant at Dearborn, Mich., are preparing a list of machine tools needed. The Wolverine Tractor Co., at Detroit, require equipment for a new tractor plant at Saginaw, Mich. The Peoria Tractor Co., East Peoria, also requires machinery for plant extension.

Railroads are placing larger contracts for bridges and structural work and also for locomotive and car repair shops. The New York Central is asking for bids on 175 machines which will cost approximately $500,000. The New York, New Haven & Hartford is buying tools for its Readville, Mass., and New Haven, Conn., shops. The Northern Pacific R. R. has also put out a list of tools required in the Chicago and Eastern markets.

The Railroad Administration in the last two days has completed the distribution of orders for material for the building of equipment for the nationalized railroads. The orders included 200,000 forged steel wheels, which will cost approximately $8,000,000, about one-third of the order went to the Carnegie Forged Steel Wheel Co. The remainder of the order was distributed among three other manufacturers. It will be recalled that orders for 800,000 cast iron wheels were placed about ten days ago. Yesterday orders for specialties required in construction of 100,000 cars were distributed among seven different manufacturers. Contracts for 390 additional locomotives which will call for about 78,000 tons of steel were also distributed. In the last week, the Government has allocated orders for 500,000 tons of steel products to be used in construction of railroad equipment, ships and manufacture of shells.

# CAN'T OVERTAKE THE DEMAND FOR STEEL

Special to CANADIAN MACHINERY.

**And Chances of Commercial Business Getting a Look-in Are Not Bright**

PITTSBURGH, June 19.—While the steel producers are not altogether clear as to some points in the new regulations as to the distribution of pig iron and steel products, adopted by the War Industries Board under date of June 6, they feel fairly familiar with the general bearing of the regulations.

One very interesting point seems clear in the minds of most steel producers, to the effect that the distribution of any surplus material that may develop after the preference list (the recognized "more essential" classes of commercial consumption) has been taken care of, cannot occur at present, or until the War Industries Board issues its promised revised list of the preference purposes. The list embodied in the resolutions of June 6 is an old list, compiled without particular reference to iron and steel. When that list is promulgated the distribution of surplus steel can occur, but only upon written consent of the Director of Steel Supply.

**A Queer Point**

The tying up of surplus steel goes farther than the actual shipment; it appears to relate to the finishing of steel that may have been produced. The regulations refer not merely to material existing, but also to the use of "manufacturing facilities." Therefore leading steel producers make this interpretation, that if in the filling of a Government order they chance to produce an "off" heat of steel, which cannot be used for the order, they must hold the heat in ingot form until instructed by Washington what finished forms to roll it into. Obviously such a thing cannot be carried far, in point of time, as ingots cannot be stored to any great extent, and also it is expensive to let them cool and heat them later for rolling.

**Not Enough Yet**

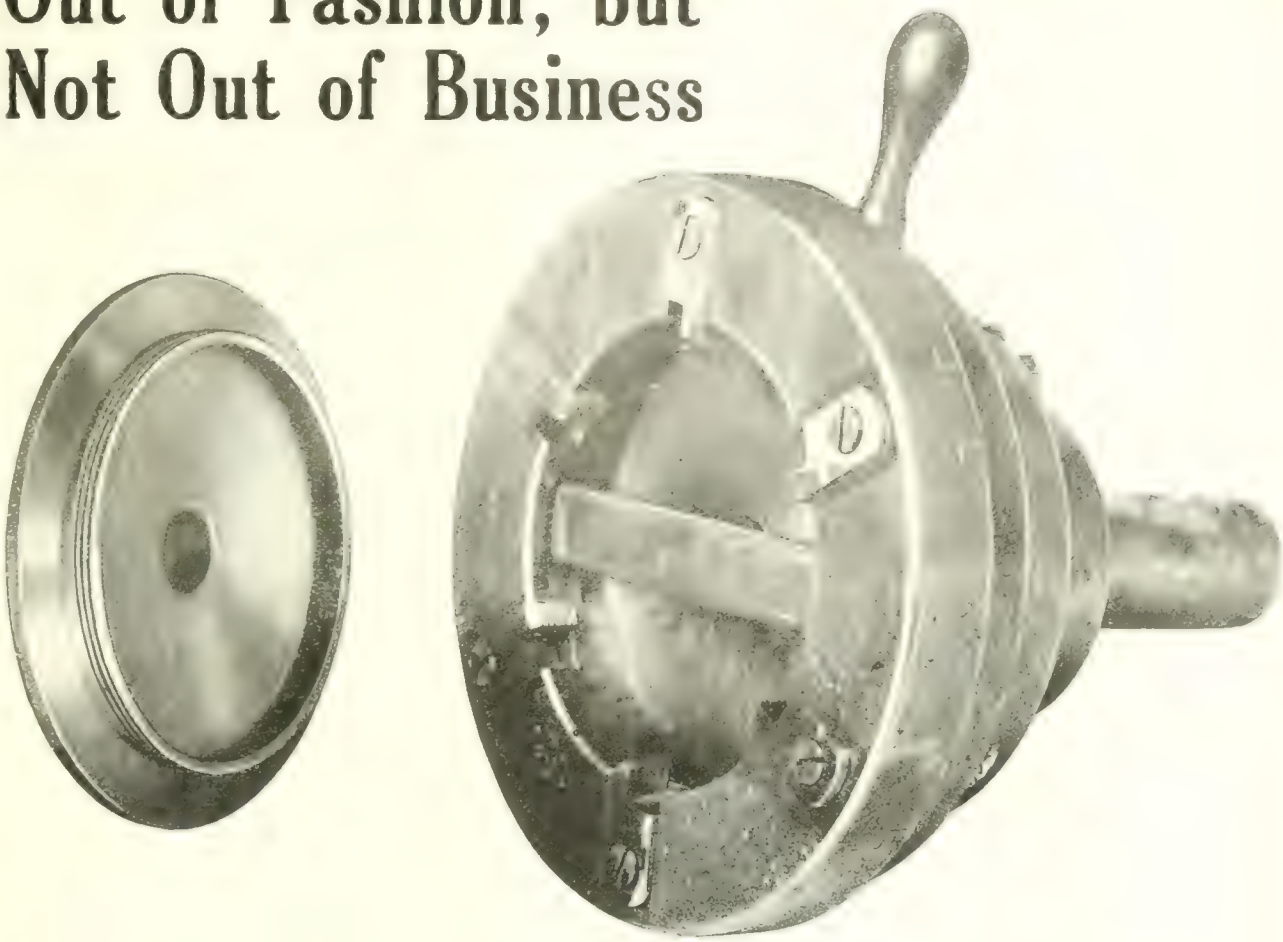
The authorities at Washington continue to insist that there will not be nearly enough steel, at least for months to come. Many steel producers adhere to their view formed long ago that the war industries cannot possibly consume all the steel, and that there must be a surplus eventually. Of course they merely hold the opinion and cannot allow it to modify their conduct, and thus they are merely carrying out the regulations. Some of them have the thought, however, that the intensive shipping of steel against the war activities will in its own due time bring the surplus to light, in the form of some of the war industries finding them well stocked with steel and expressing a willingness to have shipments to them curtailed. Meanwhile the producers have nothing to do but "play the game."

**Pig Iron Supplies**

From the current trends it would appear that even if some steel products should eventually become more plentiful, and no one can say that the balance of probability is really in that direction, it would not follow that pig iron would become more plentiful, for the iron foundry, for instance, not engaged in war work. The best estimates that can be made of capacity are that there is 43,000,000 tons of pig iron capacity and 47,000,000 tons of steel ingot capacity. While steel is made from pig iron, in general, there is normally much scrap used, and that scrap is scarcer than usual, hence it takes a larger proportion than usual of the pig iron to keep the steel works running, and the steel works are going at a less proportion of their capacity than are the blast furnaces. There is practically no new construction except in connection with the war, and that means that old bridges and buildings are not being torn down. The railroads are doing but little in rail

Continued on page 62.

# Out of Fashion; but Not Out of Business



This old "war horse" of a Geometric Die Head has been cutting Screw Threads for a Chicago concern for seventeen years. It was recently sent back to the Geometric Factory for overhauling, and has gone again to Chicago, for possibly seventeen years more of duty.

A Geometric Collapsing Tap, purchased by the same people seventeen years ago, is still cutting the inside threads to match. Can you match that?

Geometric Thread Cutting Tools of to-day can surpass it. What thread cutting method are you using? Learn the Geometric way. It is a path others have trod for the past twenty-five years. Geometric experience has smoothed the path of thread cutting for many. What will you let it do for you?

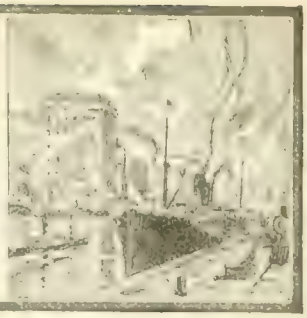
# INDUSTRIAL NEWS

## NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES



## CONTRACTS

**Hull, Que.**—The Hull Electric Com- [illegible] extensions [illegible]

**Lloydminster, Sask.**—The installation [illegible] power plant, to cost about $60,000, is under consideration by [illegible] Lloydminster.

**Shawinigan Falls, Que.**—Work, it is reported, will soon begin on the construction of a new plant for the Canadian Ferro-Alloys Company, to cost about $100,000.

**Montreal, Que.**—The contract for rebuilding the hydro-electric plant for the College de Montfort, including a concrete dam, a wooden-stave pipe line and a brick and concrete power house, has been awarded to Arsenault & Plamondon, Ltd., of Montreal.

**Vancouver, B.C.**—Mundy, Rowland & Company, of Vancouver, have been awarded the contract for the electrical work on the Manitoba Parliament Buildings at Winnipeg, amounting to more than $100,000. The company has also secured the contract for the electrical installation in the Saskatchewan Co-operative Hospital at Port Arthur, Ont., at $25,000.

**Drummondville, Que.**—The Southern Canada Power Company has awarded contract for the construction of a dam and concrete power house on the St. Francis River, near Drummondville, to Morrow & Beatty of Peterboro, Ont. The company is planning for a development of 10,000 h.p. at present, but will make provision in the power house for an ultimate development of 18,000 h.p.

**Nova Scotia Steel Record Output.**—Nova Scotia Steel and Coal Co.'s plants broke all previous records in May for steel and iron production, despite a labor shortage, according to a despatch from New York. The open-hearth plant produced 14,558 tons of steel ingots and the blast furnace 8,835 tons of pig iron, as against the previous record of 14,243 tons of steel and 8,016 tons of iron in March, 1917.

**OTTAWA.**—A contract for the construction of a 3,750-ton merchant vessel has been awarded to the Collingwood Shipbuilding Co., by the Department of Marine, Ottawa. It is the second contract let to that company since the Government announced its shipbuilding policy. The Marine Department has placed in all contracts for ten vessels. It is now engaged in the preparation of plans for the 10,000-ton ships to be built at the new Halifax ship yard.

## ENGINEERING

**London.**—The Ministry of Munitions is considering the adoption of the Madsen machine gun, the War Office announced recently. The gun weighs only 15 pounds, fires at the rate of 18,000 rounds

### MARKET REPORTS

continued from page 60.

replacements, and they are wrecking very few cars and locomotives, and thus the railroad scrap lists are small. The Pennsylvania Railroad (east of Pittsburgh) is running only about 10,000 tons of scrap a month. Then, too, a great deal of steel is going abroad, to be fabricated there, and the scrap resulting does not come out here.

#### Steel Production

The statistics of steel ingot production in May are somewhat disappointing. Pig iron production, as noted in last report, was at the rate of 40,400,000 tons a year in April and at the rate of 40,900,000 tons a year in May. There was an increase, even though it was not as great an increase as had been expected. Now the steel ingot figures appear, showing that while the rate in April was about 42,650,000 tons a year, the rate in May actually dropped to about 42,300,000 tons a year. The production of finished rolled steel runs about 75 per cent. of the ingot production, the difference being scrap, mill scale, etc., so that finished rolled steel was produced in May at the rate of about 31,600,000 gross tons a year, or about 3,000,000 net tons a month.

#### War Requirements

At the Institute meeting May 31, J. Leonard Replogle, Director of Steel Supply, stated that the unfilled war orders on the books of steel producers, plus orders he had practically ready for placing, amounted to 16,800,000 net tons. Since then news has come out of additional requirements, for early placing, involving some 3,000,000 tons more, and making 20,000,000 tons in all.

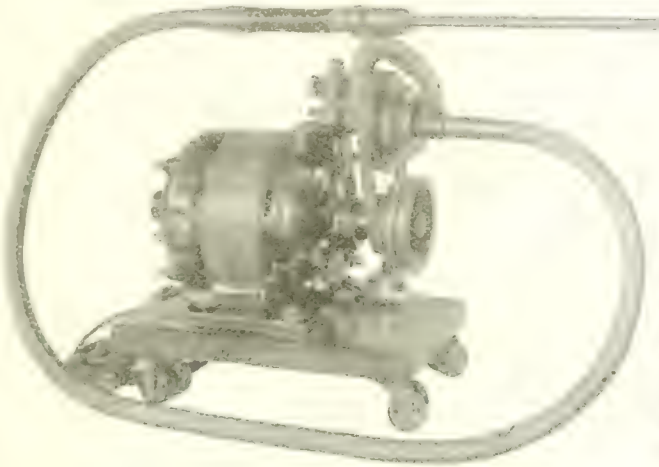
The vital question, of course, is the rate per month at which this steel will be required. If the Government were simply buying farther ahead, as its plans are developed, the mere increase in total tonnage would mean nothing. That the trade at large has no definite idea is quite certain, and one can go farther than that, and observe that there is a hint that the highest authorities as yet know very little. This hint is contained in a paragraph in the War Industries Board's resolutions of June 6, in which distribution of pig iron and steel products to the preference list was decreed. It will be recalled that on May 17 a committee was formed, of a few members of the War Industries Board and a larger number of men, leading representatives of the iron and steel industry, to determine, among other things, this very question, the prospective rate at which steel could be furnished and the prospective rate at which it would be required. In the resolution of June 6, however, the committee is given instructions as if it had not reported any very definite findings as yet, and it is asked to recommend, if possible, ways by which steel supply can be increased.

#### Prospective Prices

There is no definite hint as to what the War Industries Board will do in the matter of iron and steel prices, a subject it must decide by the end of next week, as the present set prices run only through June 30. There is a strong presumption that reductions, and perhaps considerable reductions, will be desired, particularly as the Government is taking such a large proportion of the output that taxing excess profits is not enough to equalize. On the other hand there are arguments as to increased costs, and indeed a great increase since the original price basis was decided upon, September 21, 1917, and there is also the argument that the last ton of steel possible is desired, and even if the best positioned producers do make large profits the poorly positioned producers are also needed, when six months ago it did not appear that the war needed them. The familiar argument in some quarters then was that if 75 per cent. of the iron and steel industry was given a profit, its output would be amply sufficient to conduct the war work in all its phases. That is no longer the case, for the consumption that does not help directly or indirectly to win the war has become relatively small.

# Rectifying the Inside of High Explosive Shells of Every Size

is work that takes a great deal of time when done by hand. It is work that runs into unreasonable cost without



Aikenhead's

## Flexible Shaft Grinder

It will thoroughly clean out and smooth any rough spots in the shell. This Aikenhead grinder makes the work easier and more accomplished.

Hand service will not put it out of order. An automatic stop arrangement guards against accidents. Short bends and flat curves in connection and belts prevent overheating of the motor.

**AIKENHEAD HARDWARE LIMITED**

**17, 19, 21 TEMPERANCE STREET, TORONTO**

at least. At only 12 hours are required to learn to operate it. Speaking in the House of Commons, Lord Beresford urged its adoption, declaring: "Two battalions armed with the Madsen gun could hold three divisions on a limited front."

**Ottawa.**—Establishment of a lignite briquetting plant to be financed and operated by the Dominion, Manitoba and Saskatchewan Governments, is recommended by the lignite committee of the advisory council for scientific and industrial research. The committee's report favors establishment of the plant in southern Saskatchewan "at a locality where the lignites are of poor grade, with the idea that if it were succesful at this point, it would undoubtedly be successful elsewhere in Saskatchewan and Alberta."

**Vancouver.**—Representing a total investment of between three and four million dollars, preliminary work has commenced on the establishment of a large pulp and lumber mill at Beaver Cove, B.C., 165 miles north of Vancouver. Among the heads of the company are W. H. White, Boyne City, Mich., president and managing director, and W. O. King, of Chicago, vice-president and treasurer. The company will be known as the Beaver Cove Lumber & Pulp Co., and the total daily capacity of its plant will be forty tons of pulp and 100,000 feet of lumber.

**Ottawa.**—With a view to investigation of the fuel and power resources of Canada, the "Dominion Power Board" has been created under the chairmanship of Hon. Arthur Meighen, minister of the interior. The members of the board are: A. St. Laurent (vice-chairman), assistant deputy minister, Department of Public Works; C. N. Monserrat, consulting engineer, Department of Railways and Canals; W. J. Stewart, consulting engineer, Department of External Affairs, regarding international waters; John Murphy, electrical engineer, Dominion Railway Commission; H. G. Acres, chief hydraulic engineer, Hydro-Electric Commission of Ontario; O. Higman, chief electrical engineer, Department of Inland Revenue; D. B. Bowling, geologist to Department of Mines; F. F. Haanel, chief engineer, fuel testing division, Department of Mines; J. B. Challies, secretary, chief engineer and superintendent, Dominion water power branch, Department of the Interior.

## INCORPORATIONS

**Montreal, Que.**—A new company has been organized here, to be known as Crane, Limited, with a view to manufacturing a complete line of valves and fittings, as well as certain lines of plumbing supplies. It is the intention of the company to erect a factory at once, to be planned on the unit system, so that additions may be made later as conditions warrant. The initial outlay calls for an expenditure of some $40,000. The officers selected for the new concern were: President, R. T. Crane, jr.; First Vice-President, J. B. Berryman; Second Vice-President and Secretary, E. C. Townsend.

**Ottawa.**—Halifax Shipyards, Limited, the Montreal company which, with a capital of $6,000,000 was granted incorporation, is authorized by the Government to engage in a variety of pursuits. The notice of incorporation appearing in the Canada Gazette states that the company may design, construct, purchase, lease or charter steamships, ships, dredges, tugs, scows, steamship lines, transportation lines, wharves, dockyards, shipbuilding yards, marine railways, telegraph and telegraph lines, etc., on lands owned or controlled by it. The company may also build and operate steamboat and railway terminals, transportation warehouses, storage and cold storage facilities, yards and stockyards, etc., on its own land. The company may construct steamship works for the manufacture of machines, railway or railway equipment and all supplies for steam boats and vessels generally. Power houses and structures for the development and utilization of water, steam, electric and other power may be built and operated. It can also carry on the business of transporting mail and freight upon land and water of the dominion and engage in all branches of towing, wrecking and salvage in Canadian waters.

## MARINE

**Detroit.**—Changes in the barometer pressure caused a variation of as much as two feet in seven minutes in the level of Thunder Bay and Lake Huron over its northern end. The water rose so abruptly and to such a height that wood piles along the shore were threatened. Similar fluctuations are predicted for the southerly part of Lake Huron.

**Port Huron.**—The towing tug Salvor, owned by the Reid Wrecking Company here, went down in Lake Huron, not far from Manitoulin Island. The crew reached shore in safety and are now in Georgian Bay district. The Salvor was 135 feet in length and was valued at $40,000. She was an old-time river tug and ran originally under the name of the George H. Parker.

**Detroit.**—Complaints have been received by the office of William Livingstone, president of the Lake Carriers' Association, that masters of some lake steamers are subjecting their own and other vessels to danger by anchoring in foggy weather in mid-channel just below the entrance from Lake Huron into the St. Clair River. Several vessels are reported to have narrowly escaped collision in that locality this season.

**Washington.**—Deliveries of steel ships to the Shipping Board in the first two weeks of June numbered 16, with a total weight tonnage of 89,162. Because of German submarine activity off the American coast, the Shipping Board ordered bonus of 25 per cent. of their monthly wages paid to all seamen employed on American merchant vessels in the coastwise, West Indian and South and Central American trade.

**A Pacific Port.**—Messages received here said the Pacific Steamship Company's freight and passenger steamer Ravalli was destroyed by fire en route to Alaskan points recently. When the fire was discovered the boat was beached and the passengers and crew put ashore. The fire did not stop burning until it reached the water's edge. All the baggage was saved. Most of the cargo was destroyed. The Ravalli was a vessel of 777 tons.

**St. Catharines.**—James R. Lawrence, for over 30 years paymaster on the Welland Canal, faces a charge of stealing $16,000 from the department of railways and canals. The defalcation with which Lawrence is charged dates back to the year 1892 and is altered to have taken place between that date and 1912. Last fall, at the time of enumeration for the Dominion elections was taking place, a discovery is understood to have been made which resulted in an auditor being sent from Ottawa. Further discoveries apparently followed, for the paymaster was suspended.

**Montreal.** — Another blow at the German submarine was delivered on Saturday when the 7,000 ton cargo steamer "War Earl" was launched from the yard of the Canadian Vickers Limited. The big vessel, which has a length of 380 feet and a breadth of 49 feet, took the water without a hitch amid the blowing of sirens and cheers of thousands of workmen and spectators who lined the quays. Within three minutes after the champagne had splashed over the "War Earl's" bows the keel of a sister ship was in place on the ways she had vacated, and will in turn be launched in October.

QUEBEC.—The steel rudder and tail shaft for the new wooden ship in course of construction by the Quebec Shipbuilding and Repair Co. on the Louise docks, arrived yesterday and work of installation will be commenced as soon as those large parts, weighing over seven tons of solid steel, are transferred from the Canada Steamship Co.'s landing to the docks. The propeller needed for this ship, weighing about five tons, with its 14-foot blades, is expected to arrive to-morrow or Wednesday. Just as soon as these three essentials are put in position the new 3 000-ton ship, to be christened the War Quebec, will be ready for launching.

**Detroit.**—There are several suspicious circumstances, it is alleged, in connection with a collision which occurred between two lake freighters in St. Clair River, in which one boat, the Australia, was rammed and sunk in such a way as to indicate that a deliberate attempt was made to block the Canadian channel at this point. The vessel which collided with the Australia is the B. F. Jones, one of the largest boats on the Great Lakes. The wheelsman on duty on the Jones at the time was at once placed under arrest and locked up under guard on orders from the vessel's captain, when the Federal authorities were notified of the affair. His name is withheld.

## Chilled Iron NOSING DIES Have Long Life

Since last June we have been using the same Die in our Nosing Press. In that time it has nosed over 50,000 shells in a manner satisfactory both to our own Inspectors and the Government Inspectors.

Some of our customers are getting nearly as good results, nosing anywhere from 10,000 to 25,000 shells with one die.

Others are not getting as good results, and we have reason to believe they discard the die too soon.

We find these Chilled Iron Dies will check on the wearing surface after being in use only a short time. Do not discard them then. These checks in no way impair the efficiency of the Die. They are only checks, not cracks, and the Die may be used for thousands of shells after these checks develop.

London. Twelve new British companies have been registered with the object of constructing ferro-concrete vessels. They are as follows: Marine and General Concrete Construction Syndicate, Ltd., capital £600,000; Scottish Concrete Ship Co., £10,000; Blacketts Concrete Ships, Ltd., £5,000; Gloucester Ferro Concrete Shipbuilding Co., Ltd., £20,000; Stuarts Concrete Ship Co., Ltd., £15,000; Amble Ferro Concrete Co., Ltd., £25,000; Wear Concrete Building Co., Ltd., £70,000; Concrete Seacraft, Ltd., £12,500; Aberdeen Concrete Shipbuilding Co., Ltd., £40,000; Blair-Frost Ferro Concrete Co., Ltd., £60,000; Cambelltown Ferro Concrete Shipbuilding Co., capitalization not given.

London. The "Manchester Guardian" understands that a final conclusion has been reached in the negotiations that have been pending for the purchase by a British syndicate, including Lord Pirrie and Sir Owen Phillipps, of all the vessels of British register now owned by the International Mercantile Marine Company. The transaction has yet to be ratified by the stockholders. The reported transfer price is $125,000,000, much below the present market value of the ships, which aggregate about 960,000 tons. By an understanding among the Admiralty, the Board of Trade, and J. Pierpont Morgan in August, 1903, when the combination was formed, none of the vessels could be transferred to foreign registry for 20 years from that date.

## MUNICIPAL

**Woodstock.**—The ratepayers voted on two loan by-laws and both were carried by large majorities. The Worsted Spinning Company by-law granting the concern $20,000 of a loan for purchase of site and erection of buildings, was carried by a vote of 874 to 116. The second by-law voted on was to give a grant of $18,000 to the Hosiers, Limited, the same to be applied to the purchase of a site and erection of suitable buildings. This by-law also carried by 882 to 107.

## PERSONAL

**Wilford Phillips**, for 17 years general manager of the Winnipeg Electric Railway Co., died on June 12th at Rochester, Minn., after a prolonged illness.

**Mark Workman**, president of the Dominion Steel Corporation, has rented the J. K. L. Ross property, "Cromarty," Sydney, N.S., and will leave with his family shortly to spend the summer in Cape Breton.

**Captain D. A. Waggoner**, a well-known marine man, died at the hospital at Brockville, Ont., on June 11th, where he was receiving treatment. He sailed several boats out of Alexandria Bay, which was his home. He was 83 years old.

**E. D. Cassidy**, manager of the Barnett and McQueen Company, **E. H. Smith**, of the Canadian Westinghouse Company, Fort William, and **E. B. Hagarty**, of the Canadian Government railways, Winnipeg, have returned after a week's very successful fishing trip near Ameson, on the C.G.R. They have been fishing in virgin country about 500 miles north-east of Fort William. They found speckled trout very plentiful, and the fish they caught were beauties, averaging two pounds in weight. The Nagogami, White and Skung rivers are easily accessible from Ameson. There is excellent canoeing on these rivers, and the district is a veritable paradise for fly fishermen.

**Capt. Eugene Cowles**, well known to Montreal residents, is on sick leave at his home, 14 Tower avenue. He has not only won promotion in two years from second lieutenant to his present rank, but is as well the recipient of the Military Cross. He won his decoration in leading a party of sappers in the capture of Hill 70, near Lens, on August 15, 1917. Captain Cowles is a graduate of McGill University, class of 1910. Upon taking his degree, he spent five years in Johannesburg, South Africa, as a mining engineer. The call for volunteers brought him to London in 1916, where he enlisted with the Royal Engineers, going overseas with a tunneling company on March 28, 1917. He was wounded, and spent two months in hospital in England. He is now on sick leave until October.

## TRADE GOSSIP

**The Spartan Machine Co.** of Montreal are making preparations to change over from the 4.5 to the 4.7-inch shells. A small extension will be made to the present plant to accommodate the additional equipment that will be required to maintain the desired output. The machinery has recently been rearranged to increase the efficiency and the operations are proceeding with more regularity.

**The Fuel Situation.**—CANADIAN MACHINERY has the following as a reliable summary of the coal situation:—"So far as trade conditions are concerned, dealers are making deliveries as fast as they can and generally are bare of stocks. Demand for all grades of coal is greater than the supply. Lake shipments so far have been below expectations, though carrying capacity is plentiful."

**The Standard Machinery and Supply Co.** of Montreal have acquired the selling rights for the special purpose shell lathes manufactured by the Tolland Manufacturing Co. This firm is successors to the Foundry and Machine Co., the original designers and makers of these machines. Several improvements have been added to the previous design which greatly increases their productive efficiency.

**To House Employees.**—The Brantford City Council granted a special concession to the Dominion Steel Products Company, which will erect 100 homes to cost from $3,000 to $5,000 for its employees. The land assessment will remain the same for five years, and only half of the building assessment will be taxed for general purposes, though in full for school and local

# Success and Your Associates

ALWAYS associate with men who are earning more money than you are. Such is the advice given by a man whose name is known the world over for his own success and the business which he created. It is good advice of a certainty, but we are not urging that it is the best advice. At the same time it is wise to associate with better or bigger men than you are yourself, because you are likely to be lifted up to their levels.

Most of us would probably like to be the intimates of J. P. Morgan, or of John D., or of Charlie Schwab, or Canny Andrew. If we had a speaking acquaintance with John Wanamaker, or Lord Beaverbrook, or Lord Shaughnessy, and with other distinguished and successful men, we would take comfort from the fact.

And most of us would feel rather small and uncomfortable if we were placed beside President Woodrow Wilson at a dinner table, or beside Sir Robert Borden, Sir Herbert Holt or Sir Wm. Mackenzie. And the reason would probably be that we know so little of the knowledge that really counts. If these successful business men engaged us in conversation we would probably find ourselves knowing very little about the things that matter.

This will illustrate the point:

Here's a true story. A Toronto manufacturer found himself on a train going to Albany in company with a number of distinguished Americans about to attend the inaugural ceremonies of a State Governor. A washout led to a delay, and the Canadian was thrown into close association with senators and congressmen and prominent lawyers. They bantered the little Canadian about Canada. He had the pluck of a bigger man. He had been a constant reader of THE FINANCIAL POST, and had absorbed many facts about Canada. He surprised his American travelling companions with his positive, well-informed and wide knowledge of Canada. When the company reached Albany, the Canadian was persuaded to attend the ceremonies and was introduced as the man who knew all about Canada. The Governor was interested in Canada, and said so, and the little Canadian found himself telling the story of Canada very ardently to a very attentive listener, much to the amusement of his friends who introduced him.

This man made a hit on that journey, and many friends. One of the company gave him a stock market tip worth a fortune.

The point of this story is: You, as a Canadian, can make yourself very fully and intelligently if you become a regular reader of THE FINANCIAL POST. You can make yourself a worthy companion and intimate of presidents and magnates. The world likes to listen to men who know something well, and who can talk interestingly and informingly on the subject of their study.

You can become worth listening to if you know your Canada well. And you can get the kind and amount of knowledge concerning Canada which will make you interesting to others if you will read THE FINANCIAL POST regularly each week.

IF you read THE FINANCIAL POST REGULARLY you will find yourself keeping company with the highest paid staff of editors engaged on any publication in Canada—trained men who know how to make others know what they know and learn.

You will find yourself living in a most interesting world—the great, throbbing world of business. You will have your thoughts tremendously stimulated and helpfully directed. You will find yourself becoming a fit table companion for big men—this because you will have knowledge of a quality that will keep you from shame.

What is it that keeps you and THE POST separated? It cannot be its subscription price of $3. Probably it is because you are not very well acquainted with this paper.

We are going to put it to you this way: If you have the desire to be worthy of association with big men, then prepare yourself for such association by reading THE POST, and to make acquaintance easy, we provide the coupon below. It offers you THE POST for four months for a dollar bill.

---

The MacLean Publishing Company, Limited,

143-153 University Avenue, Toronto.

Send me / us THE FINANCIAL POST for four months for One Dollar. Money enclosed / to be remitted

**Canadian Canners Get in Tin Plate.**—The War Trade Board of Canada has made arrangements with the War Trade Board of the United States whereby canners of Canada will be enabled to obtain supplies of tin plate from the United States at an approximate price of $7.75 per base box of 300 pounds. An order-in-Council has been prepared by which the Canadian Government will take power to purchase on behalf of the canners the total supply of tin plate necessary.

**Haldimand.**—The town is considering the purchase of a fire engine from the Waterous Engine Works, of Brantford. The engine is to be a four cylinder, 48 horsepower water-cooled, and a gasoline tank with a capacity of 11½ gallons. A rotary pump with a capacity of 300 to 350 gallons per minute, with heating device to prevent freezing, and the drive is a direct connection to engine by means of flexible coupling and friction clutch. The purchase price is to be $3,500.

**New Greaves-Etchells Electric Furnaces.**—The Electric Furnace Construction Co., Philadelphia, is installing a 6-ton Greaves-Etchells electric furnace at the Mare Island Navy Yard, San Francisco, Cal., for making special steel castings for naval vessels. This brings the total of this type operating or contracted for in the United States to 13. New 3-ton Greaves-Etchells electric furnaces have been started up at the Leyland Motor Works, Leyland, England, and at Stewarts & Lloyds, Ltd., Glasgow, Scotland. They will both make high-grade steel castings.

**Makes a Record.**—A wonderful record in an important branch of war work has been made by Annie Irving, who is employed as a grenade filler in a munition filling station in the south-western district of London. In nine hours she filled 6 036 hand grenades with high explosives. Her score during the first hour was 50 boxes of 12 grenades each, and gradually increasing her speed during the afternoon, she turned out a box full each minute, and for the last two hours more than a box a minute, or one grenade in less than five seconds. She was assisted by a squad of cementers, screwers up, painters, packers and examiners.

**The Wheeler Condenser & Engineering Co.**, of Carteret, N.J., has, under agreement with the Sugar Apparatus Manufacturing Co., acquired the exclusive right to manufacture and sell evaporating apparatus under the patents of S. Morris Lillie, president of that company. The advice of Mr. Lillie is to be at all times at the command of the Wheeler Condenser & Engineering Co., and at the same time Mr. Lillie will have the co-operation of the entire engineering, sales, shop and erecting organization of the Wheeler Company. This combination will doubtless result in service of the highest character.

**Carbonate of Ammonia.**—The Canada Food Board has made arrangements with the United States War Trade Board, by which a limited quantity of carbonate of ammonia has been allotted to the Canadian trade. The allocation will be made by the Canada Food Board, and the latter will issue import permits. These permits must be attached to the applications of United States shippers to the War Trade Board at Washington. Canadian manufacturers desiring to import carbonate of ammonia should make application to the import and export section of the Canada Food Board, Ottawa, stating their monthly requirements.

**Southern Canada Power Co. Extensions.**—Southern Canada Power Co. has completed its high tension transmission lines, with the necessary substations, etc., connecting the cities of Sherbrooke and Granby. This line, which is of 48,000 volt capacity, passes through Magog, Knowlton, Foster, etc., and is now in operation supplying Granby and the intervening territory with electric power. Work on one of the company's large hydro-electric developments at Drummondville is progressing very satisfactorily, over 250 men being employed. This plant will have an ultimate capacity of 17 000 h.p. and it is expected two units, with a capacity of over 7,000 h.p., will be in operation by April 1st next. The company are also building additional high tension transmission lines connecting Drummondville with the city of Sherbrooke.

**Platinum Scarcer.**—Attention is called to the shortage of platinum in a circular letter sent out by the War Trade Board to jewelry manufacturers and dealers in Canada, appealing for their co-operation in the administration of the order-in-council passed on May 29, governing the prices and sale of the metal. The platinum requirements of the allied governments are much in excess of any production that is expected to be forthcoming, and in view of this the board requests that the regulations be strictly observed. Manufacturers or persons trading in platinum are asked to furnish J. W. McConnell, Director of Licenses, with an inventory of all platinum, platinum scrap and articles containing more than 25 per cent. in value of platinum held by them. According to the regulations no platinum can be purchased or sold unless the deal is first authorized by a license of the War Trade Board. Further, no platinum scrap can be used for the manufacture of any ornament or article of jewelry, except under license by the board.

## TENDERS

**Montreal.**—Tenders are being received up to the 24th by Rev. P. G. Vaugeliste, parish priest, No. 2808 Drolet Street, for the construction of a church. Plans can be seen at the office of the architects, 230a St. Andre Street, Montreal.

**Ottawa.**—Tenders will be received until 12 o'clock noon, on Friday, June 21, 1918, for dredging required at the Eastern Channel of the River St. Maurice, at Three Rivers, Quebec. Contractors must be ready to begin work within thirty days after the date they have been notified of the acceptance of their tender.

R. C. Desrochers, secretary, Department of Public Works.

**Toronto.**—Bulk tenders for all trades required in connection with the removal and reconstruction of upper part of tower to combined police station and fire hall in Exhibition Grounds will be received by registered post only, up to noon on Tuesday, June 25th, 1918. Plans and specifications may be seen and forms of tender and all information obtained at the office of the City Architect, City Hall, Toronto. Address T. L. Church, Mayor.

**Ottawa.**—Tenders will be received up to July 2, 1918, for the lighting fixtures required in the reconstruction of the Parliament Buildings, Ottawa. The work of this contract shall be proceeded with as indicated in the schedule or as may be directed and in such a manner as to ensure the completion thereof by November 1, 1919. Plans, specifications, schedules and any other information required can be obtained at the office of the general contractors, P. Lyall & Sons Construction Company, Limited, Ottawa, Ontario

**Ottawa.**—Sealed tenders will be received up to and including twelve o'clock noon, Friday, June 21, 1918, for the construction of about 2.7 miles of railway from a point on the main line of the Intercolonial Railway at Moffat Station to a junction with the International Railway, about seven miles from Campbellton, N.B. Plans, specifications and blank form of contract may be seen at the office of the chief engineer of the Department of Railways and Canals, Ottawa, Ont.; at the office of the chief engineer, Canadian Government Railways, Moncton, N.B., and at the office of the resident engineer, Campbellton, N.B.

**Ottawa.**—Tenders will be received until noon, July 2, 1918, for the hardware required in the reconstruction of the Parliament Building, Ottawa. All tenders are to be based on the supplying and delivery to the site of all hardware included in the schedule of quantities as required and described by the plans, specifications and schedule for hardware. The work of this contract shall be proceeded with as indicated in the schedule or as may be directed and in such a manner as to ensure the completion thereof by June 1, 1919. Plans, specifications, schedule and any other information required can be obtained at the office of the general contractors, P. Lyall & Sons Construction Company, Limited, Ottawa, Ontario.

## CATALOGUES

**Air Compressors.**—The Canadian Ingersoll-Rand Co., Sherbrooke, Que., has issued a bulletin describing the class "P L B—2" power driven, two stage, cross compound air compressors. The principal features of design and construction are given in detail accompanied by a description covering the general design. Particular attention is given to the air valve feature of this type of compressor. The illustrations include views of details showing their design.

Scandinavia Belting
Is a Good Belt for Dusty Places
there is lots of dust this belt is producing results that are very satisfactory for the mill operators.
and you want a belt that will not come apart when only partly worn through.
"Scandinavia" is this kind of a belt - there are no plies to come apart it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends the surface of the belt was smooth.
Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one,
Federal Engineering Co., Limited
172 John Street, Toronto
Note—Do not use "bar" or "stick" belt dressing on textile belts.

"Barnes-made" SPRINGS
are the result of over sixty years' experience in spring making, combined with unsurpassed equipment and the workmanship of men who have been with us ten, twenty and in some cases thirty years.

## Germany G oatsOver Decrease in American Advertising

Significant Paragraphs from Famous German Papers

*From the Berlin "Tageblatt," Apr.* 26, 1918.

"If the despised Yankee nation think they are going to win the war and force Germans out of foreign markets there is nothing to indicate this sentiment in their local and foreign advertising. Many of their advertising agencies have closed their doors through lack of patronage. Their much-talked-of captains of industry have cancelled advertising contracts everywhere. Germany and German merchants have increased their advertising space in neutral markets and at home. It pays to advertise in war as well as in peace. The farseeing merchant never stops advertising."

---

*From the Berlin "Lokal Anzeiger," Apr.* 20, 1918.

"Nothing is more acceptable to the German nation than to note the fact that the North Americans have abandoned advertising their goods in practically all of the foreign markets. In the Latin-American publications, the market which they have always tried hardest to acquire, there has been a heavy loss of advertising. A prominent Buenos Aires agency announces the fact that 83% of their United States advertisers have cancelled their contracts. This is also true in the Orient, and a careful compilation of the decrease in advertising there shows a greater depreciation than in South and Central America. In the United States itself there is not a paper which has not suffered a loss in its advertising lines, and that despite the fact that the last year showed an increase in the millionaire class of 973 individuals. In other words, the war has terrorized the American nation, but not the Germans, for a perusal of their periodicals will show that manufacturers still advertise even if they have not the goods to deliver, but with the idea of keeping their name before the public."

---

Let the Germans tageblatt all they like. It makes them feel better and it doesn't hurt us; they are playing ostrich. The great majority of Canadian and American technical publications show heavy increases in advertising carried. CANADIAN MACHINERY carries three times as much advertising as it did before the Kaiser let the war dogs loose.

STELLITE

*"Not Steel but its Master"*

STELLITE no longer needs an introduction to the trade, but new developments and applications are constantly arising and should be brought to your attention.

This can be most readily and satisfactorily accomplished by a personal interview with one of our representatives who can call on you at your convenience.

As an instance of how you might be benefited we submit the following:

"A large manufacturer of gears recently installed STELLITE Milling Cutters for roughing his bevelled gear blanks with the following results:

Table feed increased from 2⅝" with H.S. Steel to 3¼" with STELLITE, an increase of 23.8%.

Cutter revolutions increased from 60 r.p.m. with H.S. Steel to 90 r.p.m. with STELLITE, an increase of 50%.

Production between grinds increased from 10 with H.S. Steel to 15 with STELLITE, an increase of 50%.

And not only this, but he was able to make the cutters for 1-3 of what he had been paying for H.S. Cutters."

Why not benefit by his experience and write us for further particulars?

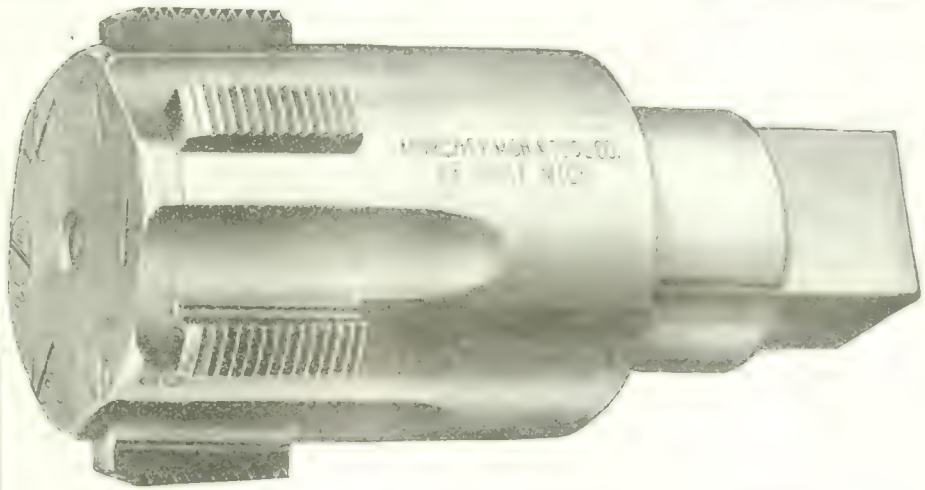
# Our Six Chaser Model



Our Four-Chaser solid screwing tap made a big hit. Then there came a demand for a six chaser model. Here it is.

## How they Keep Expenses Down

Those six chasers may be ground over and over again, making them as good as new with each grinding.
This gives a distinct advantage to the Murchey Head Solid Tap over any solid tap.
Murchey Tools handle threading and tapping operations in one-half the time of ordinary tools. If you want to keep your expenses down and get work out fast, use Murchey Tools.

We make a specialty of quick service—no waiting on chasers.

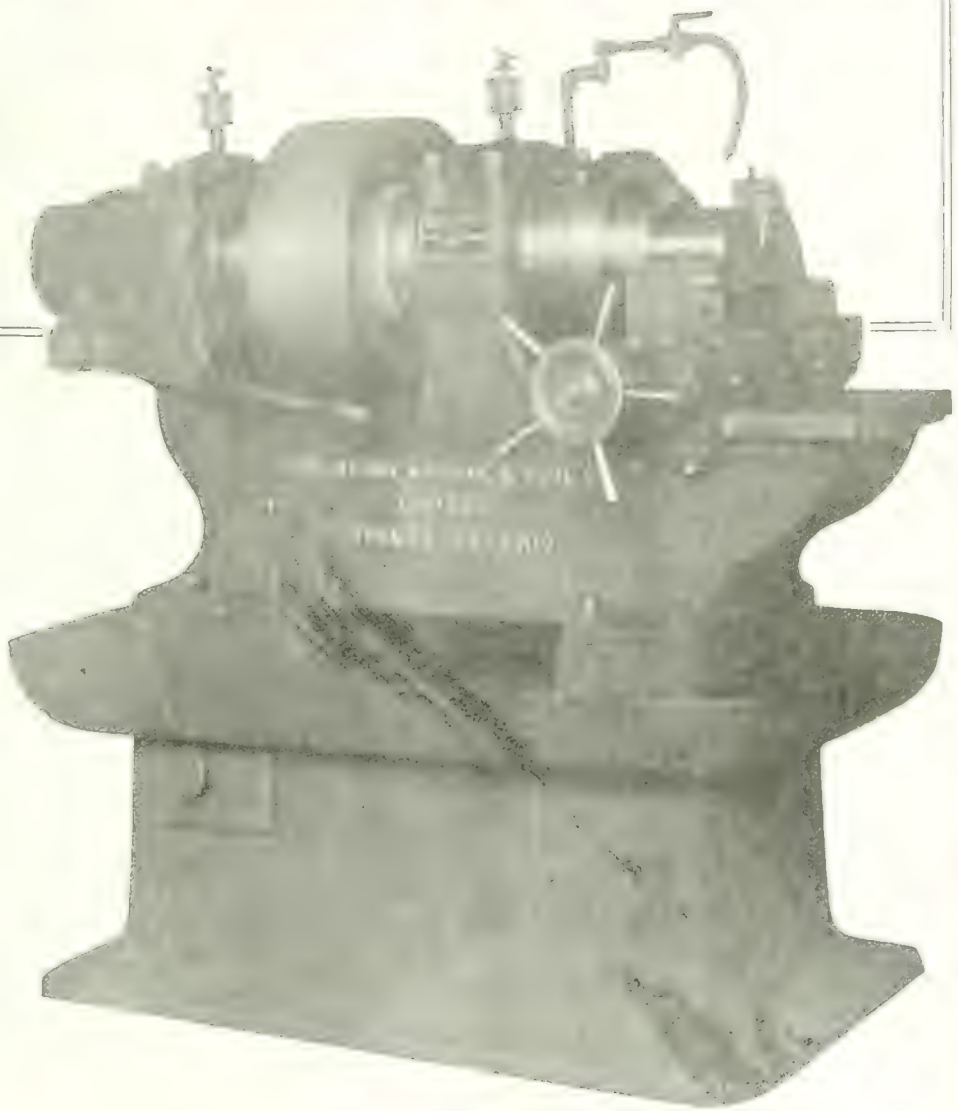
# Roelofson Banding Machine

***for 75 mm. and 155 mm. Shells.***



## Excellent Delivery

Our manufacturing facilities are such that we can make excellent delivery on machines for the above sizes. To shell plants changing over to the 75 mm. and 155 mm. shells this should be of especial interest.

## Experimenting in Munition Making is Past

AND likewise experimenting in munition machinery is past. The "experiments" are all in the discard and only the machines properly designed and carefully built have survived.

Roelofson Band Turning Machines have stood up consistently under three years of the severest service possible. They have met every requirement of production and serviceability and are still doing duty in many Canadian munition plants.

Don't experiment with your 75 mm. and 60 mm. shells. Use the machine that has a record of three years of service behind it.

**Note these features of construction:**

**Integral (en bloc) construction assures perfect rigidity, permanent accuracy and desirable compactness.**

**Chucking with spring collet chuck insures accurate and speedy chucking.**

**Graduated feed dial, two cutting tools, and ample belt power insure output of accurate work in least possible time.**

**Machines are also built for 15, 18, 60-pdr. and 6-in. shells.**

## Oxy-Acetylene Welding and Cutting

### *Conservation vs. Waste*

Oxy-Acetylene Welding is proving a great economic factor in the Factories, Mills, Railroads, Mines and Machine Shops of Canada. The Nation's scrap pile is one of the worst enemies of Conservation. Hundreds of thousands of dollars' worth of damaged, worn or broken tools, castings, pipe and machine parts lie rusting on the scrap piles of this country. Much of this enormous waste is now being eliminated by Oxy-Acetylene Welding. Losses due to breakdowns—resulting in "tie-ups" of operating equipment are also being greatly reduced.

cylinders

**Prest-O-Lite PROCESS**

of metal and repair work. It handles repairs quickly and efficiently—often right on the spot—makes broken or worn parts strong as when new—saves time which would be wasted waiting for replacements—abolishes the "Scrap Pile."

The welding outfit is portable—available for outside work as well as for shop use.

No matter what other welding method you now use, a Prest-O-Lite outfit put to work in your shops will quickly pay you profits.

Write NOW for special literature and data that will point out ways to reduce waste and increase efficiency.

Magnolia Metal Co.

Gentlemen:—

Replying to your inquiry as to the results obtained from the use of your Magnolia Metal in the manufacture of the Acme Centrifugal Pumps, and the general repairing of Gas Engines, I am pleased to advise that the results are satisfactory in every respect.

During many years as a mechanic I have used babbitt metal of many different grades and various makes, but have come to regard Magnolia Metal in my work not only advisable, but absolutely necessary to obtain the maximum in results.

Yours very truly,

G. C. KUECHLER.

# Producing 9.2 in. Shells with Women Operators Exclusively

## The Plant Where These Pictures Were Taken Employs Men as Foremen Only, Two Day and Two Night—Girls Operators do Toolsetting as Well as Shell Machining—How British Firms Meet Scarcity of Men

DESPITE the increasing demand for men by the British forces, the continued call for munitions on a gigantic scale is being successfully met by the producers in that country. The accompanying illustrations and data, which we reproduce through the courtesy of "The Engineer," are of a highly interesting series of tools for the production of 9.2 in. high explosive howitzer shells, specially designed by W. Littlejohn Philip, and operated entirely by girls. The only men employed on the production of the shells are two day foremen and two night foremen, who supervise the work throughout, and, assisted as far as possible by the girl operators, attend to the toolsetting.

### Types of Machines

The major machines employed on the production of the shell bodies are four in number, and are known as the A, B, C, and D machines. They are all of Mr. Philip's patented design. The fifth, or E machine, is a converted Herbert lathe. In Fig. 7 a self-explanatory diagram is given, showing the work performed by each of these five machines.

The first, or A, machine is illustrated in Fig. 1. The shell forging as received is placed over the mandrel A. The mandrel slides in a headstock, and with the shell in place can be rapidly pushed forward. In this way the shell is brought, with its bore correctly aligned, within the chuck headstock B. Two sets of six chucking screws are then tightened down against its exterior, whereafter the mandril is released and withdrawn, and the machine started up. On one side of the chuck the nose end of the shell is roughed down to about ¼ in. over size, and on the other side the base end is parted off and the exterior slightly coned, as indicated in Fig. 7. The coning is required in connection with an operation performed on the shell between the A and B machines.

Before the shell is passed on to the B machine it is centred by means of the cone turned on its base end in the press, shown in Fig. 2. This press is provided with a set of three tools that being advanced into the bore of the forging cut three light equally spaced grooves for a short distance up. These grooves, as revealed by the curled shaving left at their upper ends, can be seen in the bore of the shells on the bench behind the operator in the engraving. The grooves are required in connection with the driving of the forging in the B machine, and are, of course, turned out when the shell is bored in the C machine.

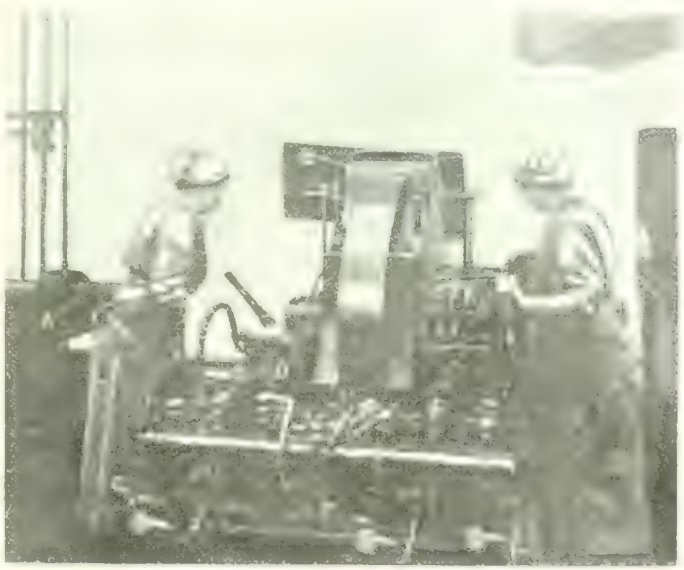

FIG. 1.—FIRST OPERATION MACHINE.

### Operating Details

The B machine is illustrated in Figs. 3 and 4, the former showing it engaged drilling the fuse hole, and the latter showing it reducing the parallel part of the body. Three sliding keys working against inclined planes cut on the mandril towards its rear end enter the grooves in the shell bore, while expanding dogs at the forward end centre the nose of the forging with the bore. The tailstock being drawn back, the machine is started up and the hinged boring fitment F is hinged back out of the way, and a hardened steel bush is driven into the fuse hole by means of the tailstock. This bush remains in position during the turning of the body and the nose, and supports the end of the forging on the back centre.

The cross slides carrying the roughing tools for the parallel body part, and the roughing and finishing tools for the nose, are operated in a manner similar to that followed in connection with the tools of the A machine. The finishing tool slide for the parallel body is fitted with a screw and hand wheel with a micrometer dial for fine adjustment. Both the saddle and cross slides work in conjunction with heavy, easily adjusted stops.

The C machine is illustrated in end view in Fig. 5. In this case the shell is held in a spring collet chuck, which is tightened up by means of a hand wheel and gearing at the rear of the headstock. The saddle of the machine carries a long cross slide, shown in the foreground of the engraving. The cross slide has four boring bars—two for the parallel bore and two for the bore at the nose end—which can be brought into position cross-wise, and when located by a stop rising from below and secured by locking bolts can be fed longitudinally.

The D machine illustrated in Fig. 6 is probably the most interesting of the series. In its arrangement of saddle and cross slide it somewhat resembles the C machine, but otherwise it is quite different, for it has essentially different duties to perform. The cross slide carries the thread milling attachment and all the other tools required except those used for undercutting the driving band groove. The machine is driven by belt during all the operations except that of

FIG. [illegible] CUTTING DRIVING SLOTS.

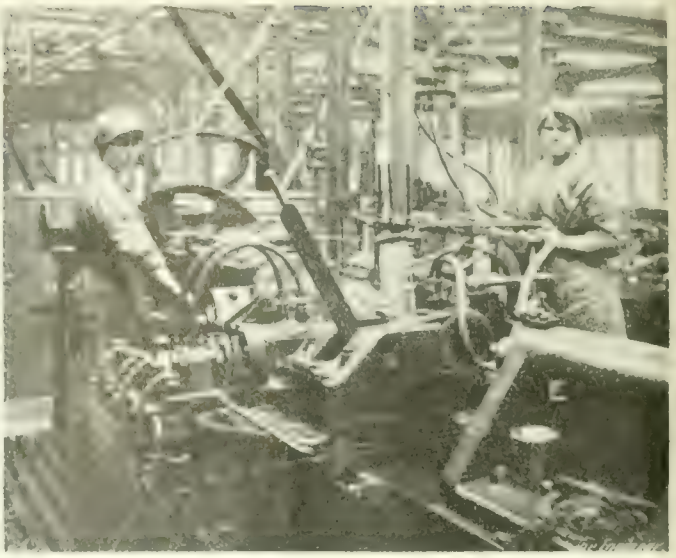

FIG. [illegible] DRILLING FUSE HOLE

[illegible] driven by an electric motor.

### Adapter Operations

In Figs. 8 and 9 the two machines employed to machine the base adapter are shown. The first operation faces the base of the adapter, turns its flange, and forms the recess behind the flange for the finish of the thread. The recess behind the flange is cut by a tool brought down vertically. The chuck on this machine is of the four-jaw independent type. The edge of the flange during the operation is not turned strictly parallel, but is formed slightly conical away from the operator. Thus when the adapter is turned round and inserted in the collet chuck of the second machine, the collet fingers, pressing down on the bevel of the flange, securely prevent the adapter from tipping or altering its position in the chuck.

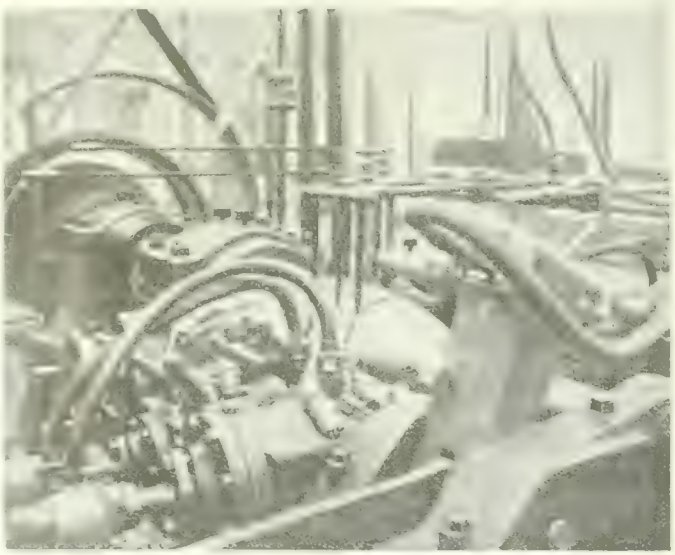

FIG. 4—TURNING.

The second operation machines rough and finish turns the body of the adapter, faces it, forms the small reduced parallel portion at its end, and threads the body. The machine is fitted with a turret, on which are tools for turning the body. Simultaneously in operation with these tools another, on a vertical overhead slide, descends and faces the end. The screw thread is then cut by means of a chasing arrangement on the turret. Leaving the second operation machine, the adapter is taken to a third machine, where the inner face of the flange is skimmed, and the bevel on its edge removed.

### Band Work

After the shell has been

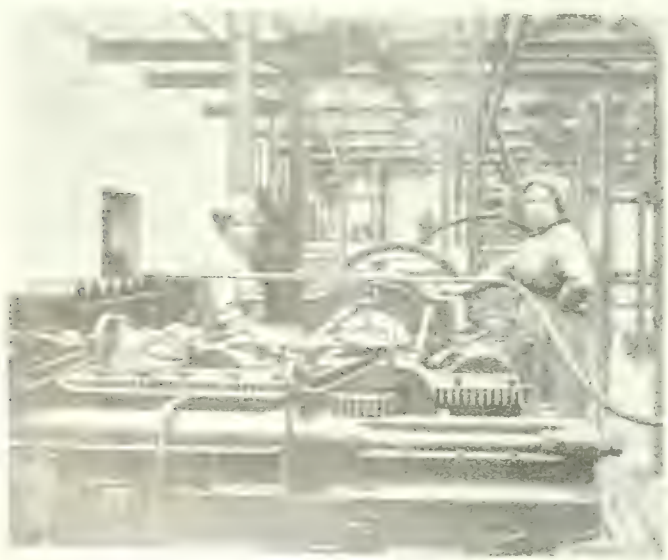

FIG. [illegible]

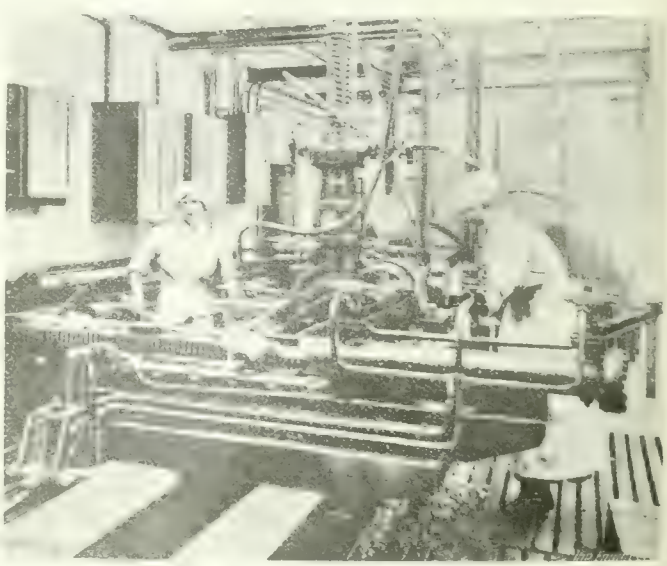

FIG. 6—THE D MACHINE

FIG. 10 COPPER BAND TURNING.

banded it is taken to the machine shown in Fig. 10, a copper band-turning machine representing an entire departure from the ordinary design. In it the shell is held nose downwards in a vertical spring collet chuck, tightened from the side of the machine. The rough forming tool is carried on a slide situated to the left of the machine, while the finish forming tool is carried on a similar slide on the right-hand side, but disposed at right angles to the first. The finish forming tool can then pass right across, and in both cases the cut is taken in one operation over the full width of the band. The machine is driven electrically. A machine on the same principle is employed, as shown in Fig. 11, for finishing the base of the shell after the adapter has been fixed in place.

The building in which the plant is housed was specially erected for it, and was completed in six weeks from the start of operations. The lay-out of the factory is such that the shells throughout practically never leave the level at

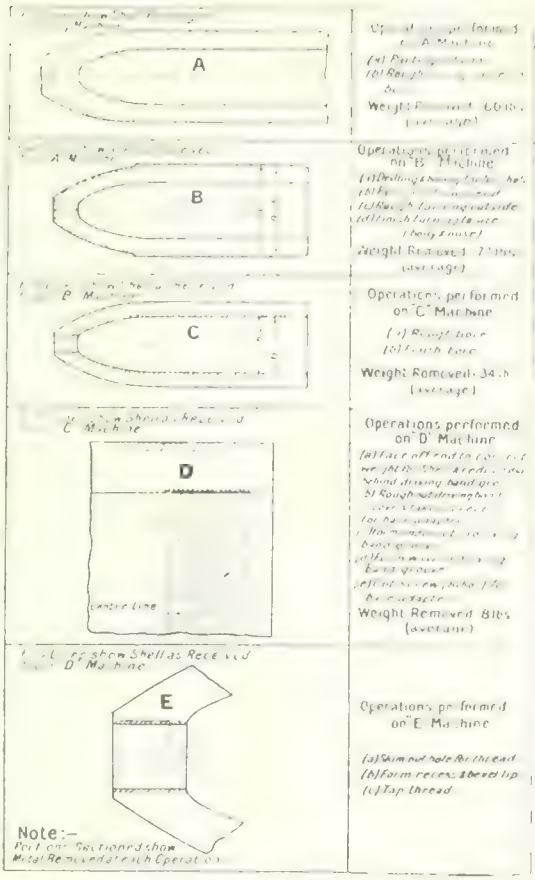

FIG. 1 DIAGRAM OF OPERATIONS.

which the machining operations are performed on them.

## DECIMAL COINAGE BILL

The text was issued recently of the bill introduced by Lord Southwark in the House of Lords to sanction a decimal system of coinage.

It is provided that "each coin shall be a thousandth part of the multiple of a thousandth part in value of a sovereign, and such part is in this Act called a 'mil.'" Bronze coinage is to be divided into one, two, three and four-mil pieces,

FIG. 11 FINISHING SHELL BASE.

and a five-mil and a ten-mil piece of nickel or other metal or alloy are proposed. The silver coins proposed are a quarter florin (25 mils), half florin (50 mils), florin (100 mils), and double florin (200 mils).

The bill, if passed, is to come into operation at such date as the King may by proclamation direct.

SOME interesting remarks on the present position and the future of the electrical industry in Australia were made by Mr. W. Corin when vacating the presidential chair of the New South Wales section of the Electrical Association of Australia. He pointed out that the war has given an impetus to the manufacture in Australia of electrical apparatus. He considers there is a distinct field for the development in New South Wales of the large electro-chemical and electro-thermic industries requiring a steady supply of power, and thinks eventually the water-power of the country will be utilized, notwithstanding the comparative cheapness of coal.

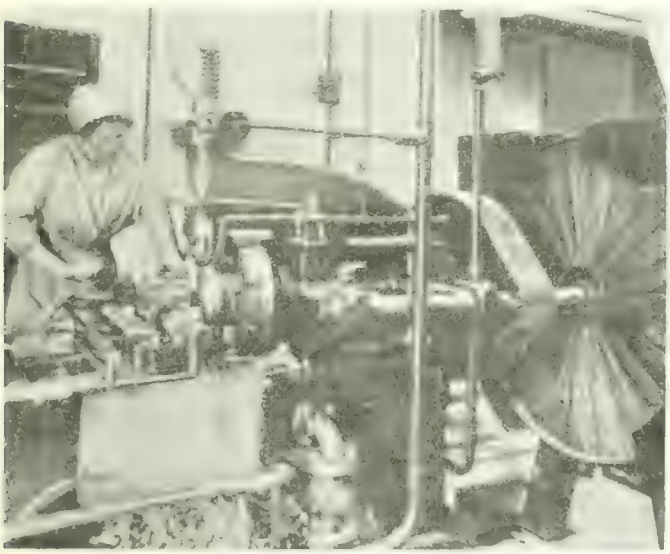

FIG. 8 MACHINING BASE ADAPTERS.

FIG. 9 MACHINING BASE ADAPTERS.

## UNSINKABLE SHIPS

By H. Stone

The safety of all seamen at the present time attaches towards making ships unsinkable by submarine action, and many ways and means have been proposed, one of which is by increasing the reserve buoyancy of ships, that is, making provision to convert the tremendous force of the torpedo explosion to the advantage of the ship. One of the methods of making ships unsinkable through the increase of their reserve buoyancy is that suggested by an Italian, whose method consists in lining all the available superficial parts of the ship's interior with a light substance such as cork. For instance, a steamer, a two-deck cargo boat, about 395 feet long and the usual lines, with a displacement of about 11,500 tons fully loaded, carries about 8,000 tons deadweight, and has about 423,000 cub. ft. of space available for cargo and bunkers under the main deck.

In order to render this vessel unsinkable it would be necessary to line the vessel internally with about 211,000 cub. ft. of cork composition having a specific weight of about 441 pounds to each 35 cub. ft. The cost of lining such a ship acording to this method would be about $200,000, whilst the capacity of such a ship would be decreased by 1,200 tons deadweight. The immediate objection to this scheme is that it is no easy matter at present to find cork in sufficient quantities to line ships. Now practicability and expediency are about the last things which enter the heads of those who propose means to safeguard ships against sinking after they have been struck by the deadly weapon known as the torpedo, against which nearly all schemes of protection adopted in the case of warships—which are not handicapped in the matter of internal subdivision through the necessity of reserving large compartments free from obstruction for the tonnage of cargo—have proved illusory, as is well demonstrated by the few instances on record of ships remaining for any length of time afloat after being struck in a vital spot by a well-aimed torpedo.

Still less commendable is a scheme put forward for increasing the buoyancy of ships by placing small watertight boxes in large numbers within the hull of a vessel and of distributing them in such a way as to interfere very little with the cargo capacity. The principle of the method proposed is that the aggregate floating capacity of the boxes will be sufficient to support the vessel and cargo after the hull is torn by a torpedo.

Another method has been suggested for attaining this end by reinforcing the hull covering the vital portions of a ship. And as time goes on other ideas and methods will be put forward, and time alone can tell which is the best method of safeguard, but there is little doubt that even as engineers evolved the submarine so other engineers will find the means of protecting vessels from these very annoying creatures of the sea.

## COMMISSION ADVOCATE DEVELOPMENT OF ST. LAWRENCE POWER

"Within a very few years there will be a demand for every horsepower that can be developed on the St. Lawrence River to which Canada is entitled for use upon the Canadian side," states Sir Clifford Sifton in the ninth annual report of the Commission of Conservation which has just been issued. "The situation with regard to Niagara will undoubtedly be duplicated," declares Sir Clifford, "and if we are foolish enough to allow vested interests to be created on the other side of the line we shall inevitably find ourselves handicapped and embarassed as we now are with respect to Niagara power." He contends that a thorough study of the situation reveals that there is only one sound method of developing these powers, viz., under "an international commission under which the best use of the powers will be made, the most economical development effected, and a just and equitable division of the power will take place for the benefit of the people who are directly concerned in its use."

Special prominence is laid in the report on power and fuel problems. Following a comprehensive review of the progress of conservation in 1917 by Sir Clifford Sifton, are addresses on "Peat as a Source of Fuel," by Dr. Eugene Haanel, "The Fuel Situation in Canada," by Fuel Controller C. A. Magrath, "Power Possibilities on the St. Lawrence," by A. V. White, "The Niagara Power Situation," by the same author, and a comprehensive treatment of the subject of railway electrification by S. T. Dodd of the General Electric Company, and W. F. Tye, C.E.

The results of the scientific investigations of the Commission to find out how best to regenerate the immense areas of cut-over pulpwood lands in Eastern Canada are also given. Dr. C Gordon Hewitt deals with the "Conservation of Wild Life in Canada," and Mr. J. P. Babcock with the "Salmon Fishery of the Fraser River District." In addition a full account of the work accomplished by the commission during the year in regard to water powers, town planning, mining, agriculture and game conservation is given. An interesting feature is a chart showing how the German metal-buying combination controlled the metal markets of the world before the war.

## MAY ESTABLISH LIGNITE PLANT

ESTABLISHMENT of a lignite briquetting plant, to be financed and operated by the Dominion, Manitoba and Saskatchewan governments, is recommended by the lignite committee of the Advisory Council for Scientific and Industrial Research. The committee report, which will be issued shortly, favors establishment of the plant in southern Saskatchewan at a locality where the lignites are of poor grade, with the idea that if it were successful at this point, it would be successful elsewhere in Saskatchewan and Alberta.

The report further states: "The art of producing carbonized briquettes has passed the laboratory stage and no further information can be got by laboratory methods. The producer must face the difficulties in commercial production, which are approximately of the same order as those within the smelting of certain ores. The road to success in the briquetting problem is strewn with the wrecks of amateur attempts to do this apparently simple thing, which accounts for the fact that private capital is so chary of such enterprises. The problem, therefore, in Saskatchewan is one which should be undertaken by the Government as a public utility, at least until such processes as may be adopted are demonstrated a commercial success."

Production costs at the plant for carbonized and briquetted fuel, covering operating costs and fixed charges, are estimated at not more than seven dollars per ton. In this estimate no finance allowance has been made for the recovery of by-products, which are stated to be large and valuable.

## AMERICAN TIN IMPORTS

THE practical suspension of the importation of pig tin into the United States affects an industry turning out at the present time over $100,000,000 worth of products. All of the tin used in the manufacture of the $100,000,000 worth of tin plate now produced in the United States is imported, more than 90 per cent. of it originating in the Orient, and with the partial suspension of shipments from that part of the world, recently announced, the United States becomes more dependent upon its South American neighbor, Bolivia, which produces about 20 per cent. of the world's tin and is practically the only world producer of tin outside of the Orient. Most of the tin imported into the United States originates in the Malayan Peninsula, the world's largest producer of tin. Certain of the Dutch East India Islands in the same general section of the globe also supply considerable quantities of tin, some of which is shipped thence to the Malayan Peninsula for smelting and reexportation. Hong-Kong is also exporting comparatively small quantities of tin, produced in China, and Great Britain produces tin from her mines in Cornwall, but not sufficient for her domestic use.

SCIENCE has destroyed, is destroying, simplicity, gentleness, beauty, but only through ignorance. Ignorance and destruction are synonymous, anyway. Pierce ignorance with the light of truth and destructive forces will become constructive forces.—Horton.

# The Design of General Purpose Agricultural Tractors

By Alan L. L. Chorlton, C.B.E.

*Mechanical appliances are of great importance in the growth, production and [illegible] needed to-day. The following article deals with the problem of co-ordinating the [illegible] separated pursuits of engineering and agriculture in the design of farm tractors and affords an interesting view of the problem as approached from the standpoint of English practice.*

THE problem of providing mechanical power, to replace that of the horse, etc., in the most suitable and efficient form for the purposes of agriculture, is one of no inconsiderable difficulty, the guiding factors being such variables as the size of the farm, the class of land, the nature of crop, road transportation and the financial ones of first cost, annual charges, etc. The information relating thereto is so diverse, so variable and difficult to relate to actual fact that the mechanical engineer investigating the problems on lines he is accustomed to, finds himself at some loss where to begin, and is driven in the end, owing to this lack of precise information, to provide much of the essential data by actual experiment.

In the preparation of this paper, which was undertaken at the request of the president, the author has found the difficulty of obtaining this precise information to be very great indeed. If such information does in reality exist, it would have saved him much trouble had he had the good fortune to have access to it. Undoubtedly, there is, apart from the actual mechanics of the problem, a considerable divergence of opinion as to the manner in which the problem should be met, while, agriculturally, the views held are seldom accompanied by those proofs upon which any engineer would rely.

In this problem the difficulty of bringing together the agricultural expert and the mechanical engineer is a very real one. This difficulty is reflected in the tardy progress in this country of mechanical agricultural science, which apart from the conservatism of the farmers themselves, has undoubtedly depended upon the cut-and-dry methods so familiar in the past, and not upon scientific and technical research, the need for which at the present day is so prominently before us, and in connection with which we are so constantly admonished by the daily press.

### General and Single Purpose Tractors

Though in the main the views held by farmers may be divided into two groups, those who favor a special power implement for each purpose and those who think a general purpose machine should be provided to deal with each and all, yet the problem should undoubtedly be considered, in the first instance, from the standpoint of capital expenditure and annual charges. The average farm in this country is comparatively small, and the farmer may find it financially impossible to purchase a special power-driven implement for each of his requirements, even should he be of opinion that such a policy is a desirable one. For example, if a light tractor were purchased for plowing alone, then a power unit would be needed for threshing, whilst on the road provision must be made for the mechanical power required for transport. A fourth power unit may even be required for other purposes, thus, a first cost of, say, £350 per unit might be increased approximately to £1,050, or even to £1,400, whilst the yearly writing-off of capital, interest, etc., would be increased proportionately, each requirement now having to bear the full charge of its special machine. The effect on the working costs of the writing-off of so large a capital expenditure incurred by unipurpose machines is very material; for example, the capital charges for a tractor costing £350 suitable for plowing alone, and allowing seven years' life, and 100 acres per year, would be 10s. per acre, for 200 acres 5s. per acre, and even if an allowance is made for performance of light land work, subsequent to plowing, the cost would probably amount to 3s., equivalent to the cost of fuel (at 3 gallons per acre), and as great as, if not greater than, the wages of two operators.

The financial consideration of the problem brings out the advantages of a multi-purpose machine, a power unit—if it could be designed—to meet the majority of calls of the farmer, instead of a special power implement for each purpose. Such a desirable combination should never be lost sight of in any general investigation of the fundamental factors of design.

Though beginning with the general aspect, the progress of the investigation revealed the extent of the field covered by the application of mechanical power to agriculture as too wide for the scope of this paper and the time at the disposal of the author, and it was, therefore, in the end, as the financial aspect was considered so important, narrowed down in the main to a consideration of the possibilities of a single power unit which would meet the majority of the demands called for on the farm. There will always be farms so large or special conditions of such a nature as to allow of the purchase of special machines for each purpose with a commercial advantage; such cases, however, must be considered individually, and are not dealt with here. There is no doubt, however, that despite the questionable soundness from a commercial point of view of the use of many special-purpose units for the average farm, there still remains a strong body of opinion that the use of [illegible] implements [illegible] thing, and only the showing of the future, when the farmer has purchased on these lines, will clearly demonstrate whether due consideration had been paid to the financial aspect of the problem.

### Reconciliation of the Various Duties to be Performed

It is essential to bear in mind the incidence of the various duties called for from the tractor; will they so fall as not to conflict? That is to say, can the uses of such a power unit be reasonably well divided to cover the agricultural year with the help of horses which will be always available to a limited extent? It is held that they can, though each farmer must with his own conditions in front of him judge for himself. The requirements called for from a power unit during the agricultural year are:

(a) Plowing, dragging, rolling, drilling.
(b) Reaping, binding and leading.
(c) Threshing, pumping, pulping, chaff cutting and grinding.
(d) Transport work to the station.

These duties are not likely to exceed 70 per cent. of the total working days of the year.

It is not possible here to consider these operations in further detail, for we must confine our examination to the mechanical factors of the problem. The three principal uses which, by their requirements, govern the design of the tractor are:

(b) Land work—plowing.
(a) Road work—transport.
(c) Farmstead—threshing, etc.

(a) governs the minimum axle loading, (b) governs the maximum axle loading, (c) governs the minimum power required.

### 1. Road Work

The basic factors governing the application of mechanical power for traction purposes are adhesion and resistance.

Tractive Adhesion.—The adhesion of the driving wheels on the road must be sufficient to utilize the power developed by the engine in overcoming the tractive resistance of the load and the tractor combined. There exists a considerable amount of data relating to tractive resistance, but for tractive adhesion on common roads, little, if any, can be found. For traction on rails, the locomotive engineer has plenty of data obtained by the use of dynamometer cars, and from these have been developed recognized constants. The standard figure of adhesion is 0.25, i.e., one-quarter of the load on the driving axles can be used in drawbar-pull. It is stated that this figure rises to 0.35, but it is not advisable to use such a value in practice.

*A paper read before the Institution of Automobile Engineers.

As no adhesion values were available for steel tyres on common roads, experiments have been made to determine them. In these experiments a steam tractor was employed towing a loaded [illegible] of a recording dynamometer. In order to obtain maximum results the experiments were extended so as to traverse a steep hill, and even with this additional resistance it was still necessary to apply the brake to the wagon before the maximum value was exceeded, and slipping began. It will be seen clearly that these experiments also afforded an opportunity of testing traction resistance constants, and this was done. To make the results still more useful, the same tractor was fitted with rubber-tired wheels and tested under similar conditions. The whole forms quite a useful combination of data for the designer of tractors for common roads, and the author is much beholden to Messrs. Ruston, Proctor & Co. for enabling the tests to be carried out. These results are shown in the diagrams of experiments, Figs. 1 and 2.

From these it will be seen that the maximum value—i.e., with slipping just beginning—is for steel tires 0.56, and for the rubber tires 0.6. It is suggested that [illegible] practice where country roads have to be taken into account, a safe value for steel tires would be 0.45, and for rubber tires 0.55, or if long life of tires is desired 0.5. This means, in effect, that in getting out the design of the tractor for road transport, which duty limits the minimum weight, the propulsive effort cannot be taken as exceeding 0.45 times the weight on the driving axle for steel tires. The high cost of rubber tires for road purposes with their special wheels seems hardly justifiable for the condi-

[illegible]

From the experiments, Figs. 1 and 2, the tractive resistance for a good macadam road comes out at just over 50 lb. per ton, the diameter of the hind wheels of the loaded wagon being 4 ft. by 9 in., that the front 3 ft. 6 in. by 9 in., with steel tires. The values given in table 1 are the results of experiments lately carried out over roads in California. For the purposes of this investigation a value of 60 lb. per ton has been taken.

Having now the values for adhesion and resistance, it is necessary to inquire as to the load a farmer will require for road transport. As it is desirable that the tractor should work on the land with practically the same efficiency as a special-purpose machine, heavy axle loading is prohibited, and it becomes necessary to proportion the tractor weight to fulfil this condition, and yet permit of the requisite adhesion for hauling the load on the road.

When the tractor is hauling a wagon in ordinary service the load may be adjusted to any condition or gradient. Is there, however, any other governing condition in which this adjustment cannot be made? A load that is in one, so to speak—and here a full-sized 4 ft. 6 in. threshing machine may be taken as a guide—such a machine weighs 4½ tons, as a safe maximum, say, 4.5 tons.

The next consideration is the reasonable maximum gradient a tractor may be called upon to face. If a maximum gradient of 1 in 10, and a tractor weight of 50 cwt. is assumed, we have 224 + 60 = 284 lb. as the total resistance per ton. Then the total load of 4.5 tons plus 2.5 tons equals 7.0 tons, or a total propulsive effort of 1,988 lb., which gives us, with a 0.45 traction adhesion, a load of 4,400 lb. on the driving axle. Obviously with a tractor of a total weight of but 2.5 tons (say, 15 cwt. on the front axle and 35 cwt. on the back), this axle weight cannot well be provided. The increased loading on the axle due to the reaction of the drive, the values of which are shown in Fig. 3, provides, however, a

means of meeting this difficulty. The alternative method is to adopt artificial loading on the axle. Resolving the drawbar pull into engine power at 2 miles an hour, at 70 per cent. gearing efficiency we get a brake horse-power of the engine of 15.2, and at 80 per cent. efficiency the power would be 13.2 approximately. For still heavier loads or steeper gradients a larger power is required, and it is desirable, therefore, that this be provided if not incompatible with the other factors.

### 2.—Work on the Land

The governing factors of successful working on the land are not easily determined, and apart from the difficulty of carrying out experiments there are such intangible things as the varying opinion as to allowable pressure on the soil to be taken into account.

It may be said generally, however, that weight is a very important consideration, and must not exceed a certain maximum, whilst additional tractive effort in excess of that consistent with this weight must be obtained by other means, projections on the wheels, spuds, etc.

The pressure which worked land will bear without injurious effect upon the crops, varies, of course, according to the nature of the soil. From the mechanical point of view the limit of pressure is set by the necessity to prevent sinking into the ground, an occurrence which is seldom due to excessive weight. What usually happens is that owing to inadequate gripping power the driving wheels rotate and act as milling cutters, scraping out the soil from beneath.

The relative values of weight and spud area are very difficult to allocate so as to be able to make comparisons. For instance, a machine with a 30-cwt. axle loading and short spuds pulls partly by adhesion and partly by grip, and the latter is rendered more effective by the weight of the wheel holding the ground down during this action. On the other hand, a lighter tractor with 15-cwt. axle loading must pull very largely by grip alone, and the effectiveness of the grip is modified and reduced by the lighter weight behind it, and the greater rolling resistance per ton set up by the spuds. Hence it will be seen that the data to be ascertained are the proper relation of pressure on the land, the pressure

FIG. 7 TESTS OF TWO CYLINDER TRACTOR USING KEROSENE

against it, and the action of the rim projection, strake, spud or grouser.

We have thus three prime conditions to be met for the majority of cases:

(a) Driving axle loading.
(b) Pressure against grips or spuds.
(c) Effect of rolling resistance.

Considering first pressures that have been usual on land work, we have:

| | Lb. per Sq. In. |
|---|---|
| Man's shoes | 8.5 |
| Horse's hoofs | 20 |
| Cart tires— | |
| Load 2 tons | 40 |

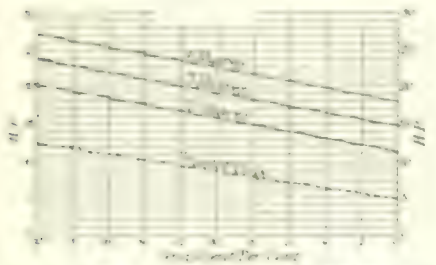
Assuming from our previous figure a static axle loading of 3,920 lb., then with the driving wheels of the tractor 48 in. diameter by 12 in. wide, we get, with a contact area of 288 sq. in. (sinkage of wheel ¾ in.), a pressure per square inch of 13.6 lb.

The second part of the problem is more difficult owing to the absence of data, but concluding that the strength of the ground is represented by its resistance to plowing, Fig. 4 is useful.

Taking the first pulling by grip alone (light tractors in Fig. 5) the suggested allowable pressures against a spud are given, and for average land 50 lb. to 75 lb. per square inch may be taken as corresponding to approximately a plow resistance of 9 lb. per square inch. If it is assumed that the drawbar pull is 2,000 lb., and the loading 50 lb. per square inch, the pull if taken by one spud in each wheel would be 1,000 lb., so that for a 12-in. wide wheel the spud would be 1.67 in. long for average land.

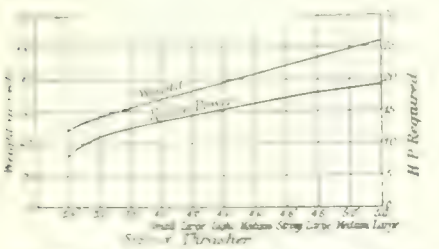
For light lands when the strength of the soil is low, with the same drawbar pull, this depth would have to be increased about four times, i.e., the spud would be 6.7 in. based upon the relative resistance given in the above table. This cannot be considered as a proposition to be recommended owing to the necessarily greatly increased rolling resistance of the tractor, and a special device becomes necessary, such as an actuated spade,

varying conditions of soil and weight of



PLOUGHING MEDIUM SOIL.

tractor. On very soft land the wheeled spud pressure, is not suitable, and one of the caterpillar type becomes essential. This, however, cannot be said to be at all



necessary for the majority of English agricultural conditions.

From the tests at 2 m.p.h. (see Fig. 7) when the drawbar pull is 500 lb. per share, the curves in Fig. 8 have been got out in which the important effect of gradient is indicated. For four shares and a gradient of 1 in 10 it will be noted that the load at the engine is 23 brake horse-power, and it is desirable that this should be obtainable if not inconsistent with the other governing factors of the design, for with four shares instead of three, 25 per cent. extra plowing will be effected for the same cost of labor.

From the tests made in dragging the tractor, the 900-lb. drawbar pull for a 3½-ton tractor is equivalent to a rolling resistance of 277 lb. per ton on land. As the tests show the loss in the gearing of the tractor is 32 per cent. of the total power, had the gear of this tractor been constructed on the lines of motor-car practice a considerably higher efficiency would have been obtained.

From the other test at 1.57 m.p.h. the drawbar pull is 2,300 lb., or 766 lb. per share, the drop in speed allowing the engine to deal with the stronger land. The peakiness of this curve shows the value of large flywheel effort on the engine.

### 3.—Work on the Farmstead

The highest power which a tractor when acting as a stationary power unit is called upon to provide is generally accepted as that for threshing.

Diagram, Fig. 9, gives an approximate [illegible] curve for different sizes of threshing machines. From this it will be seen that 20 h.p. is not exceeded, though it is usual to allow 25 h.p. for large machines. For grinding the powers are less.

Summing up now, and allowing a margin of safety on the results so far arrived at, the fundamental values for the [illegible] purpose tractor may be taken as:

| | Required Power h.p. | Driving axle Loading lb. |
|---|---|---|
| [illegible] | 18 to 20 | 4,400 |
| [illegible] | 22 to 25 | 4,400 |
| [illegible] | 20 to 25 | Stationary |

(To be continued.)

## MAY TRANSFER ROYAL NAVAL COLLEGE

THAT the decision has been practically reached to transfer the Royal Naval College from Kingston, Ont., to Esquimalt, B.C., is the announcement made recently through the offices of the capt.-supt. of the Esquimalt dockyard. The naval college, which was removed to temporary quarters at Kingston following the disaster last December, is to be transferred here temporarily, pending the erection of new college buildings at Halifax. It was announced that the naval students will be accommodated in one of the large buildings available in the Esquimalt dock yards, which can easily be converted for the purpose. It is understood that the naval students will be installed at Esquimalt by August.

## CLEANING BLAST-FURNACE GAS BY ELECTRICITY

THE gas that comes off from the top of a blast-furnace is too heavily charged with fine dust to be usable economically in hot-blast stoves and under boilers, and quite unfit for use in gas-engines. The older method of cleaning the gas consisted in natural precipitation of suspended matter in large tubes and chambers and subsequent "scrubbing" of the gas in washing apparatus. This had the disadvantage, so far as heating purposes are concerned, of reducing the temperature of the gas before combustion, which obviously is uneconomical. Consequently various dry-hot methods of cleaning have been introduced. One of these, which has proved very successful, is the electrical process. The gas is passed through a chamber, which need not be more than 15 to 20 ft. long, and subjected to high-tension electrical discharges, which precipitate the dust almost immediately without affecting the temperature of the gas. The dust can be handled much more conveniently than the wet "sludge" from the washers of the wet-cold process, especially if it has to undergo subsequent treatment for the extraction of valuable constituents. The method is cheap and extremely efficient. After one electrification, or at most two, the gas is fit for use as gas-engine fuel.

## BIG INCREASE IN CANADIAN TRADE

FOR the nine months of the fiscal year ending December 31 the total trade of the Dominion aggregated $2,068,400,971, as compared with $1,700,337,790 for the same period last year. For December alone it was to the value of $213,305,664, as against $201,193,194 for December, 1916.

Exports from the Dominion for the nine months' period included domestic products to the value of $1,257,684,900. Domestic exports for the same period last year were to the value of $851,629,813. These figures are exclusive of coin and bullion.

Manufactured goods headed the list in point of value, products of this class worth $522,963,430 being exported during the nine months' period. Last year during a like period manufactured goods were sent abroad to the value of $317,841,414. Agricultural products were in second place, with a value of $475,338,003, as compared with $317,451,444 last year.

Goods were entered for consumption to the value of $772,630,263, on which duties amounting to $125,796,830 were collected. For the like period in 1916 importations aggregated $265,635,897, on which duties amounting to $106,378,729 were collected.

Customs revenues are now dropping off a little in consequence of war conditions of transportation, scarcity of supplies and more general realization by the public of the necessity of thrift. Imports of wheat, which may be classed as "luxuries," are now considerably less than for the corresponding period of last year. The high water mark for Customs revenue was passed some time ago, and increases are not to be expected until normal conditions prevail again after peace is declared.

Allowing for a gradual dropping off in Customs revenue from now on until the end of the fiscal year, it is estimated the total revenue for the twelve months will be about $260,000,000.

ACCORDING to the *Revue de Chimie Industrielle*, the best composition for dressing the hulls of sea-going vessels is made up as follows: Six parts of tallow, melted hot, to which the following are added, and the mixture constantly stirred: six parts carbonate of lime, two parts of powdered quicklime, four of charcoal, four of sulphur, four of felspar, two of dried zinc white, thirty-three of spirit varnish, twenty-three of coal-tar naphtha, sixteen of 92 per cent. spirits of wine, and ten of ordinary varnish. To this mixture is added the coloring matter desired, in a dry and powdered form. The following additional ingredients are said to increase the efficiency of the composition: Tallow, six parts; copper, ten; iron, three; brown hematite, twenty-five.

# Principles & Practice of Mechanical Sketching & Drawing--II.

**Every Mechanic Should Know How to Make and Interpret Mechanical Drawings and Sketches of the Simpler Types—A Practical Course Prepared Especially For Younger Men and Newcomers in the Industry**

By Terrell Croft

## TAKING MEASUREMENTS FROM OBJECTS

IT has been aptly stated by some mechanically-inclined philosopher that there are three essential elements involved in the production of an engineering drawing. These three elements, arranged in the order of their importance, are: (1) accuracy, (2) neatness, and (3) **speed.** It is almost obvious that accuracy is by far the most consequential of the three, because if a drawing is inaccurate it is worthless, regardless of its appearance or the rapidity with which it was produced. Again, neatness is, in general, particularly for the beginner, of more moment than speed. The reason is that, while one may—at least when he is learning the game—be able to produce a smudgy, unsystematic sheet more rapidly than he can a neat, readily-decipherable one, the original producer is not the only fellow who must work from that sheet. It may be that many different men will have to refer to the sheet, and if it is not tidy and legible each one of them may waste considerable time in obtaining information which should be obvious.

Furthermore, if the beginner establishes for himself the rule of producing only neat drawings, regardless of the time required, he will soon become sufficiently experienced in turning out this one grade of good work that he will then be able to create a tidy, trim drawing almost as quickly as he can a dingy, illegible one. Remember: (1) accuracy, (2) neatness, and (3) speed.

### Making a Working Drawing

The general procedure in making a working drawing or sketch is about as listed in the following schedule. The different operations (Nos. 1 to 6) are given in the order in which they are usually of necessity, or at least most conveniently, performed. Under certain conditions it may not be possible or even advisable to do the work in the sequence suggested. Thus the steps are:

(1) Determine which views of the object will be shown and where they will be located on the sheet.

(2) Draw the views. (For a finished drawing the views should be drawn to scale. But for a sketch they are drawn freehand, either on plain or squared paper, to approximate scale by merely judging the general dimensions and distances with the eye. For a sketch, no dimensions are taken from the object for these plots, except, possibly, a few general ones to assist the draftsman in establishing correct proportions).

(3) Determine what dimensions are necessary to completely specify the size and form of the object and draw the necessary dimension lines and extension lines and plot the arrowheads on the dimension lines.

(4) Determine the dimensions of the object by measurement and insert the correct dimension values on the sketch.

(5) Indicate which surfaces are to be finished.

(6) Letter in the title of the sheet. (This title should consist of the name of the object and the name of the machine, if any, of which it forms a part. The part number, if there is such, should be specified and the serial number of the machine given. The date of completion should always be shown on a sketch or drawing because this information may be required some time most unexpectedly as law-suit or patent-case evidence).

The reason that the sequence above outlined is usually the desirable one is that if it is followed the draftsman in completing steps 1, 2, and 3 does not have to touch the object, which is usually dirty or oily. Thus he can readily keep the sketch sheet clean. In taking the dimensions from the object (operation No. 4 above) the hands will likely become soiled. But, by using a piece of scrap paper under the hand when transferring the dimensions to the sketch, the sketch sheet can be kept clean.

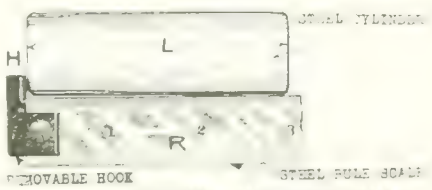

FIG. APPLICATION OF HOOK

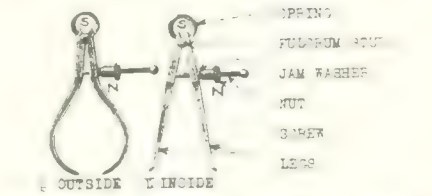
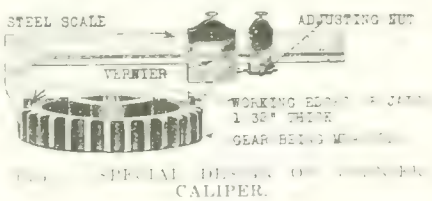


OUTSIDE AND INSIDE CALIPERS



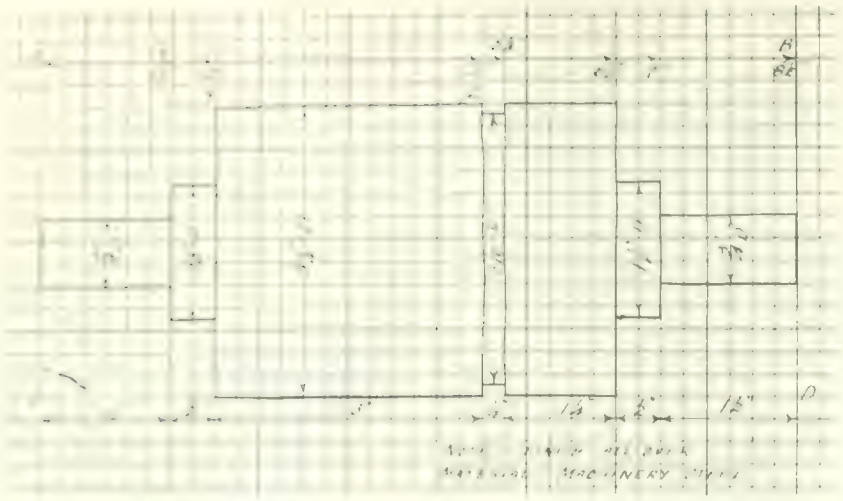
SPECIAL DEVICE FOR CALIPER.

### Use of Tools and Instrument

In obtaining accurate dimensions from objects, certain tools and instruments must be used. Some of these will be described in considerable detail in paragraphs which follow. While most of the tools to be described are in common use, the reader should not infer that he knows all about them and their characteristics. It is, therefore, advised that the paragraphs which follow be perused carefully because they contain considerable very useful information which is not generally known.

The Two-Foot Boxwood Rule (Fig. 1) is the most frequently used measuring tool. While these wooden rules are not as accurate as steel scales (which will be described later) they serve admirably for average work, can be carried around easily, and they are nearly always available. The smallest divisions on boxwood rules are ordinarily 1 16 in. or 1 10 in. It is not feasible, because of the nature of the boxwood material, to impress ac-

FIG. METHOD OF USING STEEL SCALE AND SQUARE IN MAKING DRAWING



SHOWN IN FIG. 3 DRAWN IN SKETCH PAPER

...ame and constructions of boxwood rules. It is well for him to be familiar with these, so the drawings of Fig. 2 have been included.

Boxwood rules may be full-bound, half-bound, or unbound. A full-bound rule has a sheet-brass binding, X (Fig. 2), riveted to both the inside and outside edges of each leg. A half-bound rule has the binding only on the outside edges of the legs. An unbound rule has no binding. There is no doubt but that for the average mechanic, the full-bound rule will justify its cost because of its greater serviceability. However, here is a warning: metal-bound rules of any sort are undesirable for an electrician who must take measurements around operating electrical machines or wiring installations. Disastrous short circuits have been caused by mechanics endeavoring to obtain, with a brass-bound rule, measurements around live electrical equipment.

There are three types of head-joints used on boxwood rules. These are shown at A, D, and C in Fig. 2. The round head-joint shown at A has but one wing and is used only in the cheapest rules. The square head-joint, D, has two wings and is more expensive and serviceable than that shown at A. The arch head-joint, C, is of the same general construction as that of the square joint but it contains more material and extends further along the sides, and, therefore, provides a more durable instrument.

The folding or zig-zag rule (Fig. 3) is made of flexible wood and is very useful in taking measurements where the distance involved exceeds two feet and is not greater than six or eight feet. The folding rules are not useful for the same services as are the two-foot box-

of the folding rule is that it can be used to measure the width of openings several feet wide where a tape could not, without an assistant, be used. The folding rule comprises a relatively-stiff measuring stick when unfolded, and thus can be placed across an opening, in order to determine a dimension, without being supported at the far end. It will be found that rules of this construction are most useful when one is making lay-outs of a station or taking dimensions from a building or from some relatively-large completed machine or other object.

Tapes, either steel or linen, are utilized to advantage when taking dimensions from large objects. Steel tapes of the

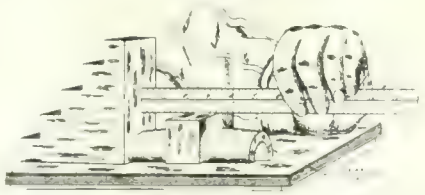


FIG. 10—OBTAINING LONGITUDINAL DIMENSIONS OF A BEARING BOX.

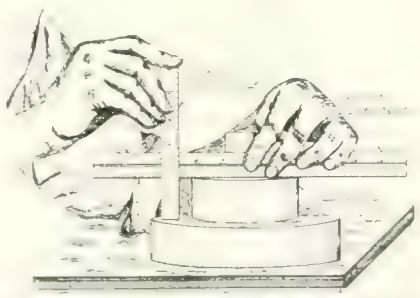

FIG. 11—USING TWO SCALES TO DETERMINE A DIMENSION

higher grades are very accurate and can be used for very close work. Linen or cloth tapes are not as accurate as the steel and are, therefore, useful only for general lay-out and building construction work where extreme accuracy is not essential. Note that a steel tape should never be used in taking measurements around operating electrical machinery or circuits for the same reasons advanced above for the undesirability of brass-bound rules for electrical work.

### Steel Scales and Calipers

The combination square comprising a steel scale and suitable heads (Fig. 4) constitutes an outfit which is almost essential to any one who proposes to make dimension sketches of machine parts. The scale or blade, B, is of hardened steel and may be obtained in any reasonable length between 4 in. and 24 in. These blades are ordinarily graduated in 1/8, 1/16, 1/32, and 1/64 of an inch, but other graduations can be obtained if desired. The blade, as suggested in some of the following illustrations, can be used without the heads. Where one of the heads is used on it the head is grooved to accommodate the blade and a dowel extends from the head into a channel cut in the back of the blade. Set screws are provided to temporarily fix the heads on the blade at any location desired. A steel scriber, S (Fig. 4), for marking metals is held by a friction clamp within the regular head. The applications of the centre head, C, and the regular head, R (Fig. 4) will be explained in subsequent paragraphs. Both soft heads and hardened heads can be purchased. The hardened heads will usually justify their additional cost.

A hook scale (Fig. 5) which is merely an ordinary steel scale with a hardened steel "hook," H, accurately adjusted at one of its ends, is a useful tool for measuring the lengths of objects which have rounded corners. In Fig. 5 the instrument is being applied for the measurement of the length, L, of the steel cylinder. Scales of this type are also convenient for measuring through the hubs of pulleys or for setting inside calipers. In the design shown in the illustration, the hook can be removed quickly by turning the eccentric stud through one-half of a revolution.

Calipers (Fig. 6) are utilized in many different ways when taking measurements. Their principal application is for obtaining a dimension such as a diameter where a scale cannot be used directly on the object. The tool used in measuring outside diameters, such as a diameter of a shaft or of a pulley (Fig. 6-I) is called the outside caliper. That for inside diameters, such as the hole through a pulley or the opening for a steam pipe, is called the inside caliper (Fig. 6II). Both of the tools illustrated are of the spring type. That is, they may be adjusted by turning the thumb nut, N, against the tension of the spring S. Calipers of this design are much more convenient for taking measurements than are the old-fashioned ones which have no springs or thumb nuts and which have to be tapped against an object in order to open or close them.

Vernier calipers (Fig. 7) are particularly useful for obtaining the dimensions of gears and gear teeth. In fact, they can be used to advantage for obtaining any dimension within their range which

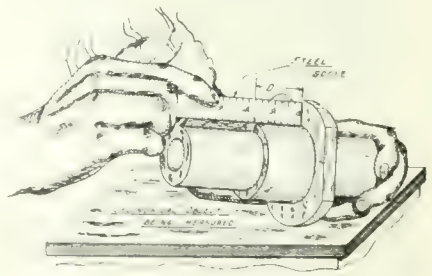

FIG. 12—METHOD OF USING STEEL SCALE.

must be measured to the nearest one-thousandth of an inch. In Fig. 7 the caliper is shown in use for determining the bottom diameter of a gear. The jaws of the tool are beveled down to a thickness of only 1/32 in. which permits their insertion in locations where a thick blade could not be used.

### Taking Dimensions

Methods of taking longitudinal dimensions from objects will now be considered. These will be discussed under two general headings, (1) small objects, and (2) lay-outs. It is impossible to describe every case which may be met in practice. The more common ones will, however, be treated and from a consideration of these the reader should be able to attack effectively any problem likely to be encountered.

In measuring longitudinal dimensions with a steel scale the general principles delineated in Fig. 8 are followed. Thus, it is usually necessary to first place the end of the object, E, against some plane surface, P, preferably a surface plate. Then the scale, R, is laid along the object with one of its ends, F, bearing against the plate. The dimensions are then read from the scale and plotted on the sketch. Fig. 9 shows the dimensions from the cylinder O of Fig. 8 plotted on squared paper. The procedure above outlined is necessary because the ends of objects—often when they are new and more often when they are worn—are rounded. Hence, unless the end is butted against a surface plate while obtaining a measurement, the observations are liable to be inaccurate. Fig. 10, reproduced from a photograph, illustrates the application of the method just described in obtaining dimensions from a bearing shell.

Occasionally the contour of an object is such (Fig. 12) that measurements may be taken along the surface of the object from one plane to another without its being necessary to use a surface plate.

To project the planes of intermediate

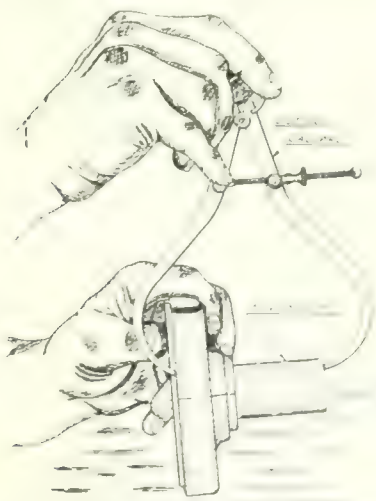

FIG. 12. MEASURING AN OVERALL DIMENSION WITH THE CALIPERS.

transverse surfaces to the measuring scale another smaller scale must be used. For example, in Fig. 8 the plane MN is projected up to the scale R with a smaller scale S, whereby it may be recorded that the distance of the plane MN from E is equal to the distance FA or 1½ in. An example showing the use of two scales to obtain the width of the face of a step on a step pulley is given in Fig. 11.

Calipers are sometimes used for measuring lengths (Fig. 13). With certain forms it is difficult or impossible to meas-

FIG. 14. DETERMINING OUTSIDE DIMENSIONS, FOUND WITH OUTSIDE CALIPERS.

ure the length directly with a scale, but with the outside calipers it may be feasible to do it. In such cases, the instrument is first adjusted to the length of the object as diagrammed in Fig. 13. Then the measurement required—the distance between the caliper tips—is

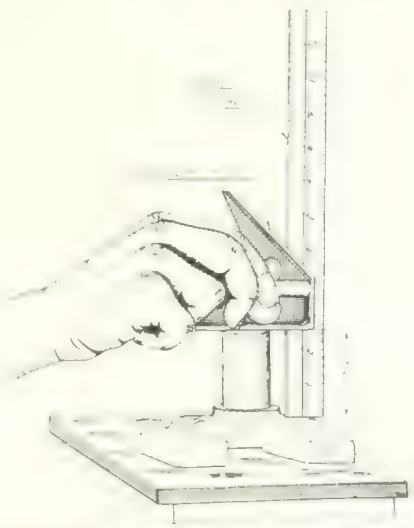

FIG. 13. FINDING AN OVERALL DIMENSION WITH THE REGULAR HEAD AND BLADE OF A COMBINATION SQUARE.

taken from the scale, as shown in Fig. 14. The tip of one of the caliper legs is held with the thumb and fingers in such a way that it bears against the end of the scale. Under the other tip the required dimension is read.

## USE OF ELECTRICITY FOR WELDING

IN spot-welding the material is placed between copper diepoints supported on the ends of two arms, and the points are brought firmly together on the metal by the use of either foot or motive power. The current is then turned on. Copper being a good conductor, provides an easy path for the flow of the current, which, however, must pass through the metal to be welded to complete the circuit. This metal is a poor conductor, and in attempting to carry the large volume of current becomes heated, and when heated to a sufficient degree, pressure is applied either by hand, foot or automatically, and the weld completed.

In case of automatic control, the current is turned on and off and the necessary welding pressure automatically applied by the controlling mechanism, driven preferably by a variable-speed motor. In this process the nicety of electric control is completely demonstrated. The current is applied to a certain definite spot only, and in just the quantity and for the length of time desired. On account of the intense heat and the rapidity with which it can be generated, several thousand welds per hour can be made in small, light stock, but the number for the heavier and more bulky stock is more limited on account of the time taken to adjust it in the machine and additional time necessary to complete the weld.

### Butt-Welding

Butt-welding is very similar to spot-welding, except that the ends of the metal are brought in contact. This junction offering the greatest resistance to path of the current, the abutting ends instantly begin to heat. The hotter the metal the greater the resistance becomes, with the result that the heat spreads to the adjacent parts until a uniform heat is obtained, at which time lateral pressure is applied and the weld completed.

Owing to the difference in cross-section of the metal at the junction in tee-welding, it is necessary to heat the larger piece to a bright red and then bring the other to the pre-heated larger piece and again turn on the current. Otherwise the piece of smaller cross-section would burn before the welding heat of the larger could be obtained.—Society for Electrical Development Bulletin.

## BALL BEARING MANUFACTURE IN SWEDEN

The British "Board of Trade Journal" states that a large company, which was formed in Sweden last October for the purpose of manufacturing ball bearings, has now started work, and will be in a position to make about 800 different kinds of ball bearings. The ball bearings manufactured by the company are of a special type, their essential feature being a pecking device whereby the bearings are made imperviable to dust, dirt, water, etc. They are thus particularly well adapted for use in vehicles and agricultural machinery. It is stated that the ball bearings for vehicles made by the company can be sold at a price which will bring them within the reach of farmers in general.

**Coal for Canada.**—Arrangements to ship 28,000,000 tons of coal to Northwestern States and portions of Canada via the Great Lakes were made by the Washington Fuel and Railway Administrations. Approximately four million tons of this quantity will go to Canada.

## FIXTURE FOR STAMPING BASE OF SHELLS

By P. Washington

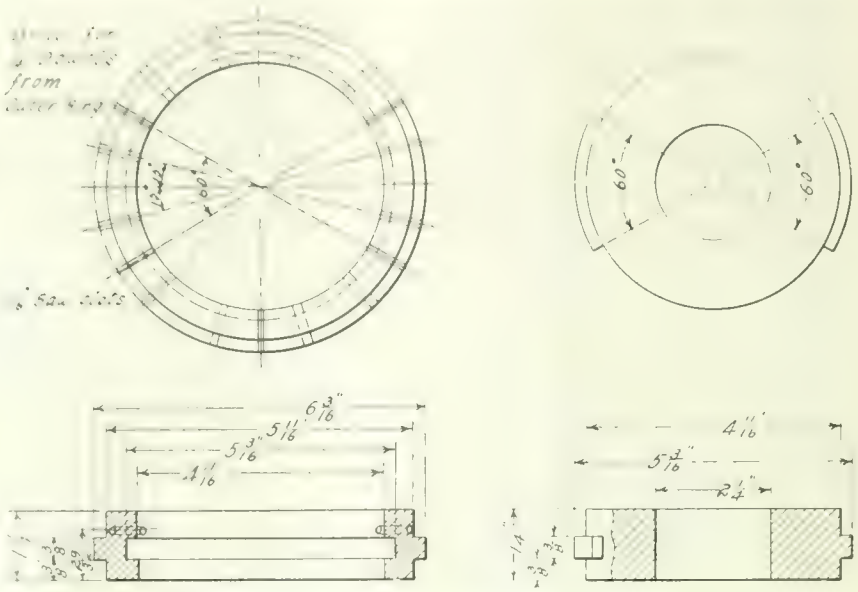
DIFFICULTY [illegible] in stamping the [illegible] on the base end of the shell.

A number of special power driven machines have been made with a cam action [illegible] to impress the stamping by means of a die. Owing to the excessive [illegible] on the machine and the difficulty experienced in holding the shell against the die such machines did not [illegible]

Some manufacturers performed this particular operation by placing a die plate over the base of the shell and dropping a heavy weight on it. This machine is so constructed that the weight is lifted by air pressure and guided by two steel rods. This device is not adaptable to rapid production and the stamps used in the die must be replaced continually.

The accompanying cut shows a handy, cheap and very efficient device for this operation, it has been used for the past three years continually in the successful stamping of various sized shells, one fixture being capable of stamping from 900 to 1,000 shells per day.

The assembly drawing shows the outer ring, which is clamped over the base of the shell by means of the two hand screws, the distance pieces which help hold the fixture together and the centre-piece are also shown.

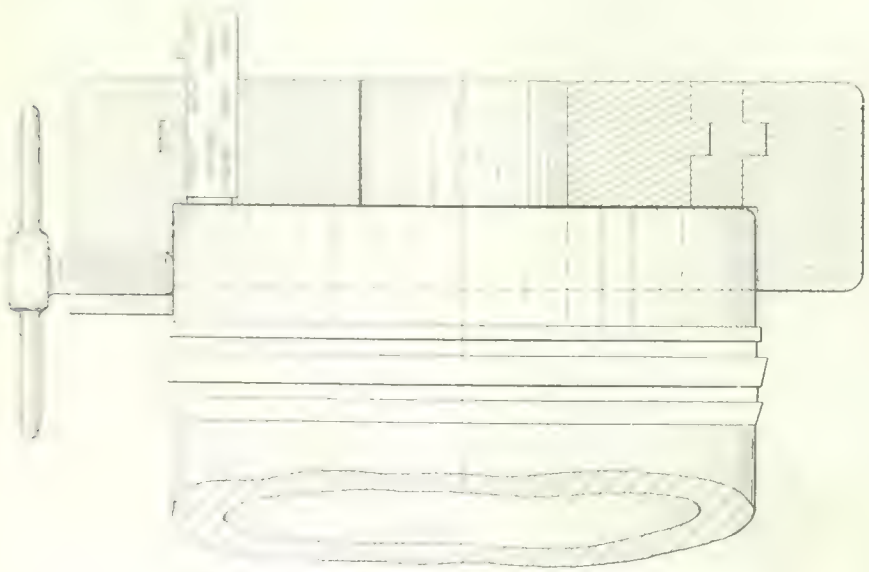


DETAILS OF FIXTURE USED IN STAMPING

Rings from which spacers (blanks to insure proper spacing of the stamps) are made are shown in detail. The detail drawings of the outer ring, centre piece, hand screw and dowel pin will enable the reader to fully understand the construction of this simple device. The blanks from which the stamps are cut are also shown in detail. These rings were turned up on a lathe, cut to the desired width and then sent out to a concern which makes a specialty of cutting steel stamps.

The length and width of the ring for distance pieces, also the spacers as well as the stamps will of course depend upon the actual stamping required, but this type of fixture can be successfully applied to any shell requiring stamping upon its base.

The shell desired to be stamped is rolled along the bench into a cradle (made of hard wood) with its base pointing upwards at an angle of about 30 degs. from the horizontal, its nose resting on a piece of heavy copper plate. The fixture is then clamped over the base of the shell and by the use of a copper hammer the impression made. By looking at the detail drawing of the stamps the protuberance at the upper end which prevents the stamp from falling out of the fixture will be noticed. A little practice will enable the operator to secure results entirely satisfactory to the government inspectors.

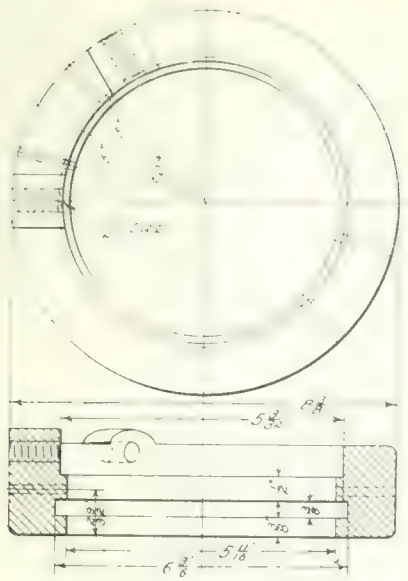


FIXTURE FOR STAMPING THE BASE OF SHELLS.

## JIG WORK ON A GUN PART

By H. Middleton

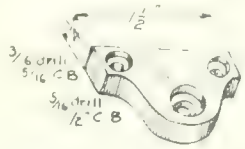
THE steel piece shown in the sketch is a gun part required in quantities. There are two sizes of holes and two counterbores. Before the war this had been done in four operations, but the speed-



DETAIL OF CLAMPING RING.

ing up process developed the arrangement shown by the photograph.

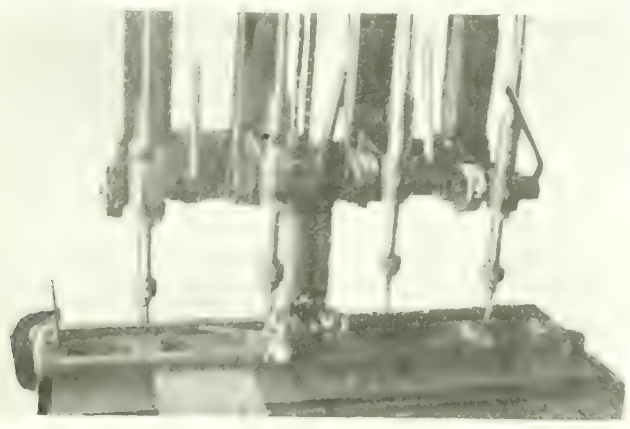
A four-spindle drill press was put on the job with a new jig and the track arrangement seen in the foreground. The work pieces were held in the jig, one at a time, and clamped by the movement of the rod seen at the left and by the latch which is shown open and which also carries the bushings for drilling the three holes. A catch at the right side of the jig holds the latch



DETAIL OF GUN PART.

down. The jig is an easy sliding fit in the track and it is gibbed down. It is thus impossible for the driller to make any unnecessary movements (with loss of time) except to slide the jig along.

The large hole is drilled by the right hand spindle and the other two by the second one. Then the catch is pulled back and the latch raised, leaving the piece still clamped, ready to be counterbored. Counterbores are used in the two spindles to the left and stops govern the depth. This completes the piece at one setting and it is more accurate than before, besides being made in less than half the time. A brush is used to apply the lubricant; this was found by trial to be more satisfactory in this case than a pump system. The feed lever on the right hand spindle has been bent to bring it more within the driller's reach and with this he easily works at all four spindles without moving in his seat.



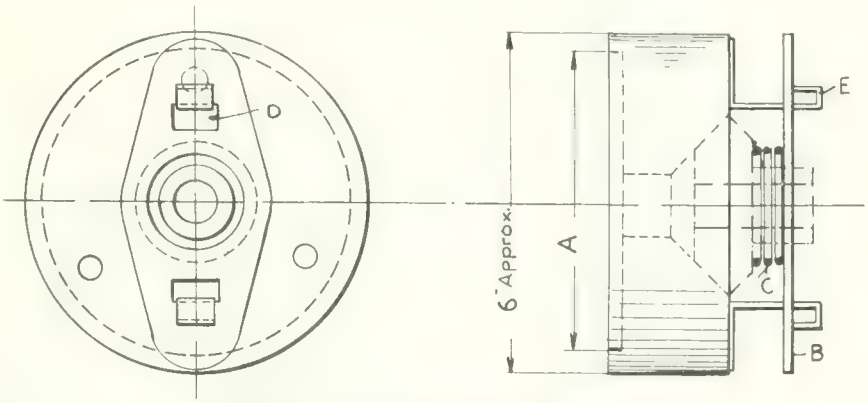
FOUR SPINDLE DRILL USED IN MAKING GUN PART.

## CHUCK FOR BEVEL GEARS

By Timesaver

SOME time ago our firm was up against the problem of turning out a large number of bevel gears for auto differential cases. Our greatest trouble was delivery, and as time was short we devised the following chuck for grinding the box. The chuck body was screwed to the chuck plate of the grinding machine and turned out at the front to suit the face angle of the wheel, the chuck plate itself being fitted to the recess A. The plate B, which is of sheet steel had the spring C soldered to it. The two side springs E, which are made of spring steel and fastened to the body, pass through the slots D in the plate B.

In operation, place the gear in the body of the chuck and push the plate B over the springs E and the bevel gear is then held in place between the chuck and plate B by the spring C. The gear is released by pushing the two springs E toward the centre and then pushing them through the slots D, thus allowing the plate B to come away; the gear is then free to be removed. This was found to give a very satisfactory result with speed and efficiency combined.



CHUCK FOR HOLDING BEVEL GEARS.

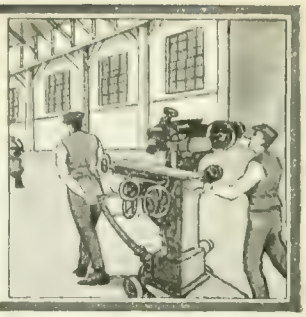
## WAYS AND TOOLS OF THE JOB SHOP

By H. Middleton

THE shop that does repair work and jobbing is the parallel to the general practitioner in the medical profession—it takes everything that comes its way and is expected to be expert and capable no matter how hard the problem and how different from the average that thing may be. It is this sort of experience that develops thinking powers and ingenuity that makes the job shop an interesting place to work in because of the variety, that makes the apprentice trained in the shop the good all around man so scarce these days. Incidentally, like the country doctor, the shop gets little credit for overcoming the handicap of inadequate tool equipment for the widest range of work and turning out jobs in a hurry without previous notice for preparation. Many job shops now take on manufacturing and tool work which gives them a chance to call themselves by the more modern and stylish name of "'contract shops"—some very small shops are self-styled as such and never make an estimate on a single piece of work, but who shall deny them the right in these days when efficiency and labor turnover are flung right and left as substitutes for shorter and simpler terms?

ALL is science if we but realize it. Nature herself recognizes only positive, working laws. Some of these laws we have mastered, some we have not, some we shall never master. But the little old laws governing my actions and your actions under certain conditions are known to some few intelligences. Let us try to make the knowledge of these few intellects the knowledge of all.—Horton.

# DEVELOPMENTS IN SHOP EQUIPMENT



*Makers of equipment and fixtures for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.*

## NEW HAND AND POWER FEED MILLING MACHINE

A HAND and power feed milling machine recently placed on the market by the Davenport Mfg. Co. embodies several features of merit.

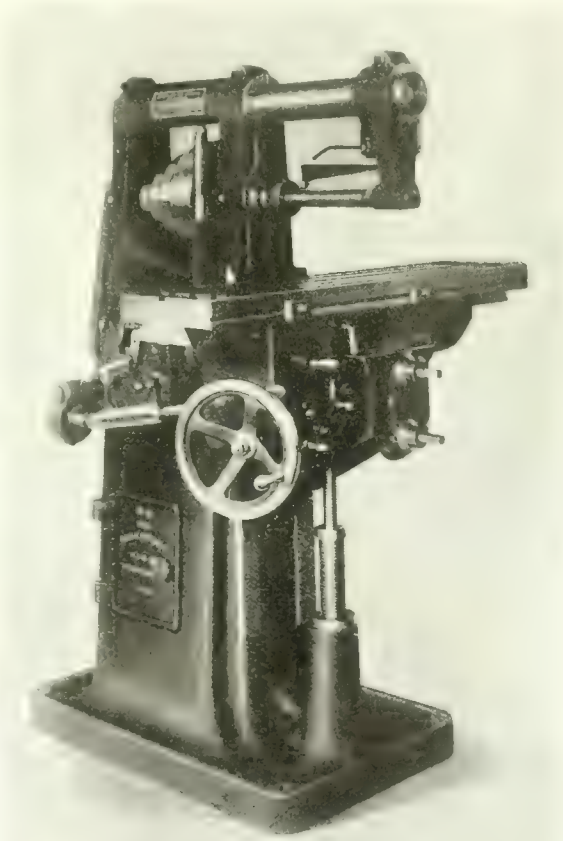
The hand feed to table is obtained either through hand lever, which gives rapid movement of table, one full movement of lever moves table five inches, or through a hand wheel, which gives a slower and more sensitive feed; the table moves ¼ in. for each revolution of hand wheel. The hand lever is made exceptionally long, and may be set at any point most convenient to operator, or may be disengaged entirely by a spring plunger. The hand wheel is located at an angle with the apron, thus making it very convenient for the operator.

The power feed to the table is obtained through a chain-driven feed box, giving six changes of feed. The feed change mechanism is contained in a single unit, assembled complete, and placed in the column, so that it becomes an integral part of the machine. It is located high above the floor which adds greatly to its handiness. All feed changes are made by two levers, and feed may be changed at any time, even while machine is operating under heavy cut. Feed reverse is obtained through push rod on feed box. All parts of the feed change mechanism are oiled from one large oil pocket easily filled through opening in column.

The feed trips have been designed with special attention towards the quick operation of the machine and are exceedingly sensitive. The automatic feed trips may be set to trip the feed at any point of table motion and to leave either the hand lever or the hand wheel connected to table motion as desired.

The oiling of the spindle is accomplished through wicks, which are supplied with oil from annular oil pockets cast around the spindle bearings. Glass indicators show the level of the oil in these pockets at all times.

The feed screws for the transverse and vertical movements are fitted with adjustable graduated dials for gauging the depth of cut. The elevating screw is made telescopic, thus doing away with the necessity of cutting a hole through the floor. Ball thrust bearings at its top make the vertical movement of the table very sensitive to the touch.



HAND AND POWER FEED MILLING MACHINE

## POWER DRIVEN HYDRAULIC STUMPING MACHINE

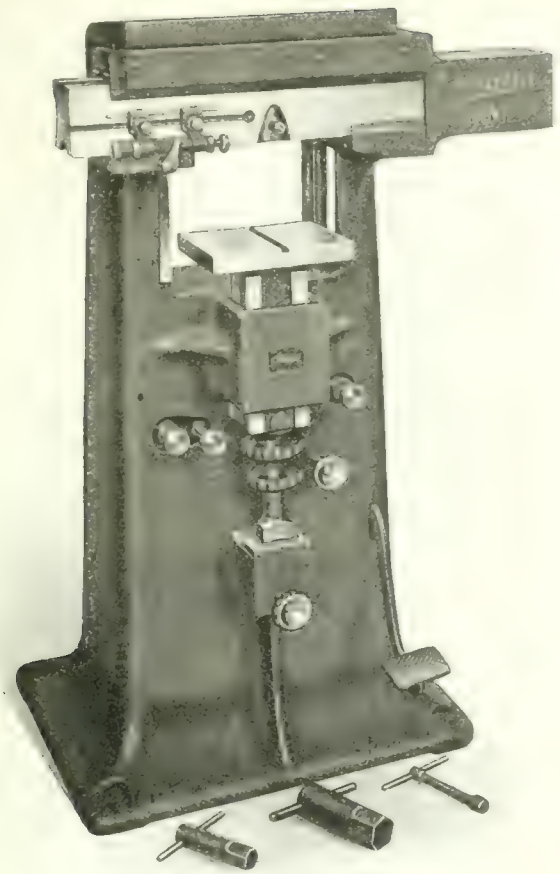
The Martin Machine Company, Greenfield, Mass., have placed a hydraulic marking machine on the market, which offers several interesting features of design.

An important feature in the design of this machine is its ability to mark even and clear impressions irrespective of the uneven working surface of the article being marked—that is, the marking pressure varies with the resistance encountered by the die in impressing the lettering.

This is effected through the compounding system inside the column of the machine, pressure beneath the work-table being automatically increased when the action of the slide in forcing die across the work becomes harder. Thus, should the pressure required for marking suddenly change during the stroke, the result would be to automatically increase or decrease the hydraulic pressure under the work-table and supply an amount of pressure to give an even impression, irrespective of the amount of lettering on the die and the unevenness of the surface being marked.

Power is received on driving pulley on rear of machine, and operates a rotary pump for the purpose of operating the hydraulic system. By means of this pump the oil pressure is maintained, and this pressure operates both the vertical table that raises the work to the marking dies and also the horizontal die-holding slide. In operation, pressure upon the foot treadle causes oil pressure to raise the work-holding table to operating point, and when this point has been reached the oil pressure also commences to act upon the slide, and then traverses the die across the work to be marked. As soon as the die has completed its marking an adjustable stop on the slide trips the reverse lever, which operates valve, releasing pressure that has moved slide forward and allowing the oil pressure to return the slide to the starting point. At the same time oil pressure beneath the work-table is immediately released and table drops back ready for the removal of the work.

The machine will mark either cylindrical or flat work, and by using special fixtures irregular work may be handled.



HYDRAULIC MARKING MACHINE.

MARKING HAMMERS BY MEANS OF THE HYDRAULIC MARKING MACHINE

In marking flat work, roll dies are used that turn as they are rolled across the article being marked. In marking round work, a flat die is used and work rolls as the die is traversed across.

All adjustments provided are readily accessible for increasing or decreasing the pressure on table, speed of slide, etc. Capacity is from 1 to 10 lines of ⅛ inch letters; maximum length of lines, 7 inches.

A feature of the machine is its simplicity and practically automatic operation, requiring almost no adjustments on the part of the operator. It may just as effectively be operated by girls and unskilled labor. For continuous marking, the foot treadle may be depressed and caused to catch, allowing the operator to devote his or her entire time to inserting and removing the work. In this connection the machine may be set at any desired speed and run continuously just fast enough to allow the work to be removed and inserted between strokes. The amount of production, therefore, depends wholly on the ability of the operator to handle the work with rapidity.

## DEMAGNETIZER

A valuable adjunct for use with magnetic chucks and holding devices is illustrated herewith. In grinding operations magnetic chucks would be more frequently used than at present if the demagnetization of the work pieces could be done more readily and efficiently. The Smith demagnetizer manufactured by the W. F. Davis Machine Tool Co., New York, demagnetizes any work instantly and completely. The speed with which the operation is carried on is limited only by the operator's ability to feed the material, and, as may be gathered from the illustration, the work passes through the demagnetizer to the hopper or box below. The cost of operation is extremely low, and little or no maintenance is necessary. The apparatus is made in any size corresponding to the size of work.

DEMAGNETIZER IN OPERATION

## THE METHANEPHONE

A YOUNG Welsh professor in London has recently perfected an invention with which he hopes to considerably relieve the mine worker from the fear of methane gas. The little instrument has been appropriately named the methanephone.

It consists of a small wooden box about nine inches in height, containing an electric battery. At the top of the box is a fuse head cap, upon which a tiny light always glows from the battery beneath. As soon as a certain low percentage of methane gas enters the working its presence causes a tiny explosion in the fuse head, the explosion in its turn melting a fine wire filament, which starts a bell to ring continuously. The men in the vicinity are thus notified that gas is in the working and can take the necessary precautions.

The leaders of the Miners' Federation of Great Britain have witnessed effective tests of the methanephone.

## SHRAPNEL DEMAND IS URGENT

IT is understood that the renewed demand for shrapnel will be more than sufficient to tax the resources of the Dominion to the utmost. Some time ago when British types were restricted to 4.5 and 6 in., most plants were changed to suit or else disposed of otherwise. Following this came numerous American contracts which absorbed much capacity as it became available.

The supply of shrapnel now required will necessitate renewed effort by many shell factories, and while past experience will enable preparations to be made rapidly and effectively, the changed situation with regard to labor and material will militate against a repetition of former spectacular accomplishments.

Patriotic impulses prompted many experienced mechanics above military age to enlist as mechanics, etc., and recent calls have taken numerous young men of high productive ability, whose places cannot be adequately filled by women. New firms starting up now will therefore be doubly handicapped—lack of experienced toolmakers for starting up and maintenance of the special machines for women workers, or, on the other hand, experienced mechanics to make the best use of such standard machines as may be immediately available.

Recent advances in machine shop practice and materials can be counted on to balance much of these possible handicaps and close study of war time developments will well repay those who may for the first time be contemplating [illegible].

## PRESENT EMERGENCY INSURES FUTURE ECONOMY

IT is a foregone conclusion that past practice in the matter of shipbuilding will not be allowed to return and dominate output as it has in the past.

The recent statement of Secretary Daniels regarding the expedited building of destroyers in U. S. yards reveals such a tremendous discrepancy between possibilities and accomplishments that it is incredible that any sane man [illegible] in the quickest way a return to former conditions.

It would seem that organization is the keynote to the whole situation. Because destroyers were wanted in a hurry, the various officials and yards concerned cooperated to an extent not hitherto equalled, with the result that the actual time from the laying of the keel to the launching was 17½ days. The conditions were such, however, that the time referred to is nearly all assembling time as much of the structural work was prepared in advance ready for erection and assembling before the keel was laid; likewise bulkheads, deckhouses, bridge structure and a section of the keel were riveted up ready for assembling in place on the ways.

With suitable preparation almost any desired record might be put up. What really counts is the actual total time on all the material in a ship, not just in putting them together.

As a matter of production management the instance is illuminating, especially when compared with results of twenty years ago when the average time from the laying of the keel to launching was almost two years. It is against all principles of economy to tie up a building slip with its equipment for twenty-four months when less than three weeks suffices. Probably much of the work now done in shops ashore was formerly carried aboard and fabricated in detail instead of being manufactured in quantities and assembled en masse.

Shipbuilders who look forward to remaining on the active list will find much profitable study in such performances. Quick delivery will always be a factor of importance in securing orders, and if this feature is accompanied by largely reduced overhead charges per hull, the present emergency will alone be memorable for having effected such changes in recognized practice.

## NEW WORLD VALUE OF MANUAL WORK

THERE used to be a current phrase which, in the new scale of transposed values, has fallen into desuetude; the term was contemptuous and its use proof of a lack of understanding on the part of the user—the phrase was, common working man.

The appellation was given indifferently to all manual workers by those unable to discriminate, and was justifiably resented by some of the most intelligent members of society.

Not so long ago it appeared that the line of demarcation was drawn between different classes solely on the ground of manual work irrespective of quality. If the war has done nothing else, it has educated the general public so that no such misconception can become current hereafter.

The truth is that the phrase separated producer from non-producer—the maker from the man on the make—for while brains can employ numberless indirect tools it is the manual worker who after all carries into being the work of designer and expert, to say nothing of the commerce founded on his toil.

The majority of men are common in that they are human, and it is the lot of most to perform common tasks—the word does not imply inferiority but rather equality. Moreover, there are only two classes in the community, those who work and those who idle, and the man who works keeps all. Man is a term of dignity and to claim the title involves much more than most critics allow. To be the man for any particular purpose is a distinction, so that the term with its implied reproach has a validity it were well to claim, not avoid.

It is upon the broad back of the common working man, that industry and national well-being rest. The manual worker is the most indispensable in the whole community, in mechanism is certainly at least the equal of most. For the combination and interplay of muscle and mind demanded by skilled manual work makes for a satisfying life, it involves both bodily and mental health and contributes directly to both. After all perhaps to be healthily tired enough to sleep soundly is among the most welcome of gifts and in this the mechanic having exercise of brain and body has a pull over many more envied men.

---

IF the success of industrial efforts in the future is to rest on the basis of "one man—one job," then civilization may well be considered to be a partial failure. The leaders of industry, and the men in the upper ranks—who have not specialized too narrowly—are able to work for longer hours and do far more work, precisely because of the interest and variety of their work. "Interest-power," which is the most important factor in efficiency is here at its maximum.

# BUSINESS GROWS AS RESULT OF HARD WORK

**Windsor Machine & Tool Works Developing on Solid Lines of Good Business**

THE careers of A. Morrell and L. Wilkie, the two partners in the Windsor Machine & Tool Co., Windsor, Ont., have been such as to ultimately fit them for the work upon which they are now engaged. Adolph Morrell is a few years senior to Lorne Wilkie but both take an equal interest and responsibility in the conduct of the business. They claim that they take it in turns to manage the two sides of the business, one looking after the commercial end and the other the shop end of the business alternately. They change about each year and are thus able to keep in touch with both aspects of the business. At the same time if the truth were told Mr. Morrell would probably admit that he preferred being in the shop and his partner in the office.

L. WILKIE

Adolph Morrell was born near Montreal in 1878; his father at the time was working for the contractors who were constructing a section of the Lachine Canal. In the same year the Morrell family moved to Detroit, Adolph being at the time about six months old. In 1884 his parents returned to Canada and settled down in Windsor, Ont. When Adolph's school days were over he became an apprentice, finishing this period with the Canadian Typograph Co., of Windsor. During the following ten or twelve years the subject of the sketch worked in various shops in the district, one of these being the Kent Engine Works. During this time Mr. Morrell, being ambitious, devoted all his time to acquiring a thorough knowledge of his trade and developed into an expert tool maker. In 1909 Mr. Morrell started on his own account in a small way, making dies, etc., in fact this may be said to have been the real start, although the following year, 1910, the partnership with Mr. Wilkie was formed and the Windsor Machine & Tool Works inaugurated.

A. MORRELL

Hard work combined with a natural aptitude for mechanics has been responsible for much of Mr. Morrell's success in life. Mr. Morrell was not born with the proverbial silver spoon in his mouth, so it has been a case of hard plugging. In this connection he has a word of timely advice to young mechanics for having been through the mill he knows what the younger generation are up against. Mr. Morrell believes in boys and young men doing general work rather than specializing, by doing so they get a more thorough training and a broader knowledge of their work. He also believes in hard work, application and study, a combination which, if intelligently applied, cannot help but turn out a good mechanic.

Lorne Wilkie, Mr. Morrell's partner in the Windsor Machine & Tool Works, was born on July 10, 1891, in Stormount county near Morrisburg, Ont. At the age of ten his mother died, leaving a family of seven others. About a year later the family moved to Windsor and have lived there ever since. Mr. Wilkie finished what education he had in the Windsor Public schools, and being also mechanically inclined went to work for the Evans & Dodge Bicycle Company in Windsor. He later worked for the Penberthy Injector Company as a monitor hand, and quit a job paying a dollar and a half a day to go to work for the Olds Motor Company in Detroit to learn the machinist's trade at sixty cents per day, a step which is very hard to convince the average young man to-day as being advisable. The Olds Motor Works burned down about a year later and from there Mr. Wilkie finished his time in approximately forty-two other shops in Detroit, which fitted him to a nicety to the new environment he found himself in when the partnership was formed and the Windsor Machine & Tool Works became a reality. Mr. Wilkie was a young man when he joined Mr. Morrell in 1910. Both partners have similar views on engineering or mechanical matters, and by applying their ideas have been able to build up a nice business from a very small beginning. A "worn-out chicken coop," they say was the title given to their shop by the inhabitants of Windsor in the early days. Needless to say there is no indication now that their shop was used to such purpose. Both Mr. Morrell and Mr. Wilkie are very enthusiastic about their business and future prospects.

They believe that production in the future will be more on a standardized basis, which will necessitate the use of gauges and other instruments of precision. By this means, not only is greater accuracy obtained, but output is increased with lower operating costs. These conditions will tend to greater accuracy in workmanship.

## Speaking of Picnics

Ah! a picnic is a joyous thing—it surely is a lark to leave the noisy city streets and scamper in the park. You take a basket on your arm, of course it's filled with grub—to go to such a thing without would stamp you as a dub.

Then someone rings a bell and says, "We're going to have the races," and hairpins decorate the turf, with corset stays and laces.

The fat man hides behind a stump, not anxious for the fray, but sure as guns he hears the cry, "The fat men come this way!"

He waddles down for fifty yards as graceful as a cow, he's squeakin' badly at the joints, the sweat drips from his brow.

Then comes the feed, and on this spread the whole crew make a raid, and some poor simp is called upon to dish the lemonade. They shoo the flies from off the cake, chase spiders from the cheese, while forty different kinds of bugs look on from stumps and trees.

There's sure to be among the crowds some killing, nifty guy, who plants his white duck trousers on a juicy cherry pie.

They eat an awful lot of stuff, these joyful picnic folks, and loud hee-haws are sure to greet the stalest, punkest jokes. At last they hook up fists and sing a verse of Auld Lang Syne, and every Ananias lisps, "We've had a dandy time."—A.R.K.

UNIFORMITY

# MARKET DEVELOPMENTS

## Price Fixing is Taking On Form Now

### Forms Sent Out to Jobbers Contain Reference to the Selling Price of the Commodity—Single Purpose Machinery Being Purchased For Use in the Shell Shops —Supplies Are in Good Demand

PRODUCTION of iron and steel keeps up remarkably well at the great producing points in United States. When iron and steel are mentioned coke is included as a matter of fact. The warm months which are so hard on men in furnace work or rolling mills have not yet arrived, and output gains to that extent. The whole industry in United States is running well up to 95 per cent. of possible production. It is quite evident that the Canadian War Board is taking definite steps toward the fixing or controlling of prices to be paid for steel and iron products. The entire output in United States has been subjected to such a ruling for many months, and it was intimated in these columns some weeks ago that the matter was under advisement at Ottawa. Forms which are being sent out now for use in releasing material from warehouses ask the jobbers to state the price per pound at which the sale was made. There is, as would be expected, not a little opposition to this move. The jobbers claim that the government want them to do business on about a five per cent. margin, and it is claimed that they cannot do this. They urge that the control of prices should go back further to the mills. As a matter of fact Canadian warehouse men will have to more and more depend on the output of the mills in Eastern Canada, as warehousing orders cannot be passed on to the mills in United States.

Several Canadian business men are in Washington this week in connection with the completion of orders for the American government. Plants are being fitted out at this late hour in the shell-making industry for the execution of large 155-mm. orders, and single purpose machinery is being purchased in large blocks for the purpose.

Orders for boiler tubes for repair work to heating plants in large schools and other institutions that close during the summer are reaching the jobbers. Fortunately in most cases the size called for is three-inch and over, but even at that there is hard work in finding material to supply the need. The tube situation does not improve. As a matter of fact it is much worse than it has been for months back, especially for the two-inch size.

Foundry owners are scouring the market for pig iron. They will go long distances to secure any odd lots, and the odd lots are few and far between and usually very small. There is in consequence a very keen demand for good scrap, but unfortunately this is hooked up with a very poor supply. Foundrymen prefer good machinery scrap to anything in the line of railway stock, but it is very hard to secure in appreciable quantities.

New munitions orders, and the element of haste that enters into them all keeps up a steady flow of business for the dealers in supplies, especially in high speed lines. There is a tendency on the part of dealers to carry more stock as it is found that orders very often go to the point of quickest delivery. Price changes have been almost entirely absent during the week.

## MONTREAL MUNITIONS SHOPS WILL TRY TO HANDLE ALL ORDERS OFFERING

Special to CANADIAN MACHINERY.

MONTREAL, June 26.—The announcement by the Imperial Munitions Board to the effect that the output of the 18-pdr. shell would be immediately doubled at the request of the British Ministry of Munitions has been the feature of the week, as the orders of a few months ago were that the work on this particular shell would be greatly reduced. The reason of this change of attitude is not quite clear, but the direct bearing on industrial activity has been to stimulate the action of shell manufacturers to renewed efforts in production. The advent of the American orders into Canada makes it a little difficult to immediately accede to the new demands, as many have turned their old equipment over to the new duties, so that in order to return to former fields it will be necessary to instal additional equipment to handle the extra business. Many shell makers, however, are acceding to the wishes of the board, and it is anticipated that within a very short time the required output will be attained. To utilize every available transportation facility an order has recently been issued by the Canadian Railway War Board asking for the co-operation of manufacturers and shippers in seeing that all cars are loaded to their capacity. This is essential, as additional cars will be required in the near future to move the crops in the West. Machinery demand has increased following the revived activity in connection with shrapnel shells.

### Steel

Little more can be said at the present time than that the steel situation generally remains unchanged, with the pressure on the mills and furnaces as great as ever. Warehouse stocks are virtually at the disposal of the Government. A fair supply of steel for urgent purposes is coming through, but none can be sold to consumers without first receiving the approval of the governing board.

While no definite announcement has been made regarding the outcome of the recent negotiations in the States relative to a new price on steel to meet the coming advance in freight rates, it is intimated that a readjustment will be made in connection with prices of ore and pig iron, but that the old prices will remain in effect on finished steel. An interesting situation has arisen over the supply of steel rails that are now lying on the Pacific Coast awaiting their disposal to the Russian Government, the initial pur-

chasers. The unsettled condition in that country makes it impossible to locate any authority with whom negotiations can be started, but certain Canadian interests are endeavoring to secure purchase of the material which is sufficient to lay about 150 miles of track. The local situation is much the same, with dealers reporting a market that is virtually controlled by the dictates of the Government and the needs of the war. A change has been made in the base price of iron and steel bars here, this being represented by a decline of approximately ¾c per lb. Iron bars are now quoted at 4.55, steel bars at 4.80 and reinforced bars at 4.50. Band steel, No. 10 gauge, is now listed at 4.80. One dealer here reports that the quotation on heads or circular plates is 25 per cent. above the base price of $10 per hundred, and intimates that the demand for such material is very light. The quotation on plates formerly noted as ¼ inch to ½ inch is now ¼ inch up, as this price relates to all thickness of ordinary plate.

**Metals Quiet, But Firmer**

The general market is one of strength, but active buying is not a feature. The steadier position of certain of the metals is more as a result of recent developments and the uncertainty of the future trend than any actual change in current conditions. Copper is strong on a steady demand. Tin is losing its nervous tone, but continues in strength. Labor conditions may place spelter on a higher basis. Lead is apparently scarce, and dealers have advanced prices. Antimony and aluminum are steady and firm.

**Copper.**—The trade, or some portions of it, are still looking forward to a further consideration of the regulation price on copper. The fact that the president has not as yet confirmed the renewal of the prevailing price for a further period, and also to the coming advance in the transportation charges, which will add to the producing costs of the metal, has been taken as a possible indication that the price may yet be advanced to cover the higher expenses entailed by recent developments. Dealers here report a steady demand for metal, and some have the impression that an upward revision in the market price is not unlikely. Present quotations remain firm at 29c and 30c per lb.

**Tin.**—The situation in tin is assuming a more encouraging aspect, although the visible supply is still short of the trade requirements, a factor that has the tendency to maintain prices at a high level. The Canadian market is still influenced by the inability to secure sufficient metal to satisfy the needs of the consumers, and, therefore, dealers are maintaining the high figures that have prevailed for the past several weeks. The situation in the States has taken on an easier tone, but little change is noted in the nominal quotations that are still a feature. The market here is not so acute, but the available metal is not ample to meet the demands of all comers. Dealers are still quoting $1.25 per lb., but state that the undertone is weaker.

The further placing of American war orders in Canada and the additional requirements that will be entailed by the renewed activity in connection with shrapnel shells has added to the pressure under which machine tool builders are operating at present. Owing to the fact that many shell makers that were working on the 18-pdr. have turned over their equipment to the production of American ammunition the supply of available tools for the increased demands for the British shell is not sufficient to meet the requirements, so that additional machines in some cases will need to be installed. Dealers report a good inquiry for the smaller sizes of special shell lathes and also for some of the heavier sizes. Shipyards are still good buyers, although their requirements are showing a falling off. The brisk inquiry and sales of small general supplies indicate the continued activity in all lines of manufacturing enterprise. Dealers report more regular delivery of material and machines from the States, but in some instances the delay is such as to cause considerable inconvenience to purchasers. The dealers here are uncertain regarding the conditions that are likely to develop after the increased freight rates go into effect, but would not be surprised if present prices on machinery and accessories were advanced during the next few weeks.

Despite the activity that continues throughout all lines of the iron and steel industry the general business in the old material market is comparatively quiet, not that the demand for scrap has fallen off, but the dealers are not receiving the volume of the business that marked the earlier activity in this direction. Much of the steel scrap that was previously placed on the open market and handled by the dealers is now disposed of between the producer and the consumer direct, facilities being provided whereby material can be again utilized without passing into the hands of the dealer. Dealers are still doing a good business in old machinery scrap, as many foundries are still unable to obtain sufficient pig to meet their requirements. Trading in the non-ferrous scraps is quite active, and quotations would indicate that the undertone is one of strength; this is particularly pronounced in relation to old lead and zinc scrap. The only price change to report is on that of zinc, this having advanced ½c to 6½c per lb.

## POINTS IN WEEK'S MARKETING NOTES

**Pig iron production is right up now at United States points with the output of coke. More furnaces could be blown in were there a supply of coke.**

**United States firms were counting on being able to buy up munitions plants in Canada, but can't do it because Canadian plants have taken on new orders.**

**One order for 300,000 kegs of wire nails for delivery in France has been placed. This is the largest single order ever placed for wire nails, whether for military or other purposes.**

**War steel requirements continue to grow at a rate greatly in excess of the ability of the Government to handle them.**

**U. S. steel mills find that under Government control they can "blame the Government" when orders for steel are turned down as non-essential to war winning.**

**Single purpose war machinery is still very much in demand, especially lathes for rough turning and boring.**

**Orders for tubes for repair work to Toronto school heating plants are being passed by War Board, although dealers find difficulty in filling them. Tubes are a scarce article.**

**Forms now used by the War Board for jobbers request the latter to state price per pound at which the sale was made. Jobbers are not satisfied with the arrangement as in force now.**

**The demand for pig iron is still far ahead of available supply, and firms continue to resort to larger mixtures of scrap.**

## A TIN MARKET THAT HAS VANISHED

Prohibition of the export of tin from Holland is now a fact, but the large stocks that were available earlier in the war have practically vanished, and the only tinfoil factory in Holland cannot execute orders because of the shortness of raw material. The price of tin today is nominally equal to £400 per ton. The production in the Dutch Indian Islands of Banca and Billiton shows a decrease, and the metal, instead of being sent to Holland for sale by public auction at Amsterdam or Rotterdam, as was done before the war, is now sold in the Dutch Indies. The Dutch government intends to abolish the auction sales in Holland altogether after the war, and to continue to sell its tin in Batavia, so that the tin market in Holland, which in any event was not of great importance, will cease to exist. . . . Tin is one of the few metals which almost entirely disappear in use, not one-twentieth part of the tin which is consumed being recovered in the form of old metal, and for that reason there is practically no market for scrap. Old tin jugs and statuettes, however, are being melted down now in Holland for solder, the present price of solder in the country being equal to from £12 10s. to £15 per cwt. Tin plates have practically disappeared from the market.

## PRICE FIXING IS BEING ATTEMPTED

New Forms Ask Jobbers to State Price at Which They Sell War Goods

CANADIAN MACHINERY

the new release sheets sent to the jobther problematical, and the ar- t would have to be rather in- rect, as the matter affects largely the product of mills outside this country.

up material to combat the short- steel is also in big demand, and equally small supply. There is a tendency to use large amounts of scrap—larger than usual, and this is keeping the market practically stripped of surplus.

off. There is a demand now for the single purpose machine tools the same as there was when the making of munitions was a new thing in this country. The dealers in supplies will no doubt feel the full effect of this a little later on when the plants are in actual operation.

Price changes are very few this week. Values for the most part are on a very high level just at the moment, and any advance that comes has to be well justified. It is predicted that there will be a general advance in the prices of all kinds of chains in the very near future. In fact it is doubtful if present quotations can really be counted upon as being the actual basis of selling.

### Regulating Prices

Advice from Ottawa to CANADIAN MACHINERY intimates that a new form has been issued by the War Trade Board called an "Application for Release From Stock." The questions on the form aae much the same as those that have been used for some time past, but they go further. They are as follows:

Material required and weight thereof.

Nature of contract for which materiai is needed, and by whom.

State whether for war work. If so, give the particulars.

Have you no stock on hand or substitute therefor?

State urgency.

State selling price per pound.

It is the last item that makes the difference between the former forms used and those now sent out. And it is right here that the indication comes that price-fixing is being more than merely considered at Ottawa. Just how it is going to work out depends on several things. Canadian warehouses cannot import now for stock, and as a result they are turning more and more to the mills of Nova Scotia for supplies. Jobbers were asked this morning for their opinion of the new form asking the selling price. There was not any anxiety to discuss it in detail, but opinions secured from other points make it clear that as a rule the jobbers are not satisfied with the new form. They claim that the regulations should go back to the mills. One dealer states that the Government expects them to do business on a basis of five per cent., which he says is a figure at which they could not keep going. There seems to be no doubt about it the jobbers will have to turn more than ever to the Canadian rollers for warehousing purposes, although the majority of their direct orders will by a large majority still be with the U. S. points.

### Orders Being Filled

Dealers are having some difficulty in filling orders for tubes. The situation does not improve—rather does it get worse every day. Orders that are receiving attention now are being farmed out between dealers in many cases, or where they have two agencies the tubes will be supplied fifty-fifty between the two. Several school orders are being placed for Toronto institutions, where repairs are carried on during the summer vacation. These are mostly for the three-inch variety, and have been attended to. "The tube situation," remarked a dealer this morning, "is getting very close to the stage where it is being peddled around."

Although no change is noted on today's lists, it is likely that another week will see an advance in the figures given for fire weld steel chain, BBB, BB or B, and there seems to be good reason for believing that the increase will be around the twenty per cent. mark. The chances are that electric weld will move up also.

### Scrap Metals

Dealers in scrap report no price changes, only a normal amount of business, with a keen demand for lines with which they are not heavily stocked. Foundrymen continue to visit the yards looking for good substitutes for pig, which is becoming increasingly short, with small prospects of much improvement right away. Foundrymen prefer machinery scrap to railroad stuff, as the latter is inclined to be much harder. Heavy melting steel is a scarce article, and very much in demand, but as is often the case, very little of it is to be had when the need is quite marked. Lead and spelter are firmer, but the movement is not of sufficient size yet to warrant a change in the listed prices.

### Machine Tools

The extent to which war work stuff figures in Canadian business can be judged from the fact that complete outfits of single purpose machinery are still being put up in Canadian cities to handle American orders. The Otis-Fensom have a satisfactory contract. They are using their Hamilton shop, where they previously handled 4.5 orders, but the equipment for the 155 mm. is entirely new. There are some few details to be worked out yet in connection with the order, but the main features are settled. It is understood that the first order will run the firm well on toward May of next year.

Supply dealers are handling a nice volume of trade. Prices have varied hardly at all. Screw plates are up ten per cent. on the list. The new munition orders keep up a steady flow of orders for dealers who are in a position to give reasonable deliveries. In fact in many cases the preference is for the man who stocks standard sizes for immediate delivery. There is not much improvement in the matter of securing delivery for Old Country high speed steel. The whole energy of the country is taxed to the limit on direct and serious war work, and although the high speed is an essential war product in this country, there are the added difficulties of rail and water transportation to contend with at present.

## THE LARGEST ORDER YET FOR WIRE NAILS

### Has Been Placed for Delivery in France During the Next Few Months

Special to CANADIAN MACHINERY.

NEW YORK, June 26.—Canadian manufacturers of projectiles have received additional contracts for shells from the United States Government. As a result of similar contracts previously placed, it is reported here that Lyall's Ltd., Montreal, has already begun the construction of a new plant and purchased equipment for the manufacture of 155 mm. shells. Carson Bros., also of Montreal, will build a new plant for the manufacture of the same size shells for the United States Government. Some makers of projectiles in the United States who expected to buy machine tools from Canadian shell makers will probably be disappointed because of the heavy demand for such machinery from Dominion plants.

The Midvale Steel & Ordnance Co. has issued a list for 120 large tools and 27 electric cranes for the manufacture of 16-inch howitzers for the new gun shop it is building at Nicetown, for the United States Government. The tools inquired for include lathes, planers, slotters, shapers, boring and turning mills, grinders and drills. The U. S. Steel Corporation has also put out tentative inquiries for machine tools to be installed in the Neville Island plant. The Corporation expects to manufacture 1,500 12-inch, 14, and 16-inch shells a day.

### Canadian Business

The U. S. Ammunition Co., Poughkeepsie, N.Y., which recently took over the Fiat automobile factory, is buying tools for the manufacture of 6-inch and 9.2-inch shells. This company is owned by Canadian capital and if tools cannot be purchased to advantage here, they will probably be brought from the Dominion. Other makers of guns and shells are buying tools, including the Bartlett Hayward Co. of Baltimore and the Grant Motor Car Corporation of Cleveland; the latter has purchased $200,000 worth of machinery.

### For Shipbuilding

Shipbuilders continue to place heavy orders for tools, cranes and other machinery and large contracts are still

# *Speed Up Production*

## *with the*

# MONTREAL LATHE

for the economical production of 4.5", 6" and 155 MM. shells. If you are interested in obtaining maximum production at minimum labor expense, investigate the records of the MONTREAL lathe in plants of the largest producers of shells in Canada.

The MONTREAL lathe is wonderfully simple in operation and construction, yet every worth while improvement has been embodied in the design.

A powerful machine—designed to transmit all the power that the cutting tools will stand—with large broad ways, liberal wearing surfaces and unbreakable apron. The MONTREAL lathe comes to you equipped as you need it—with carriage for rough turning —with rigid single bar for boring, or with swivelling bar for inside profiling.

## The A. R. Williams Machinery Co.

LIMITED

**64 Front Street West - . - TORONTO**

[illegal] ill for an expenditure [illegal] 000,000. The Bethlehem [illegal] that it will build on the Atlantic coast. [illegal] families can be adequately housed.

Heavy specifications for steel plates, shapes, bars, sheets and wire products [illegal] by the Emergency Fleet Corporation, the War Industries Board and by other Government departments in the last week amounting to [illegal] to 1,000,000 tons. The Carnegie Steel Co., alone has received orders for 250,000 tons of plates for ship and car building. The Newport News Shipbuilding and Drydock Co. will receive sheared plates for the construction of tank ships from the Pittsburg plant. The Carnegie [illegal] has a capacity of 1,500,000 tons of plates a year and its capacity for nearly the whole of 1919 as well as for the whole of 1918 has been taken up. The Quartermaster of the Army has placed a contract for 300,000 kegs of wire nails, calling for an expenditure of $1,-[illegal],000, with American manufacturers for export to France up to February, 1919. The allocation of the order was recommended by the wire committee of the Iron and Steel Institute. This is the largest single export order ever placed for wire nails whether for military or for other purposes.

# BLAMING THE GOVERNMENT IS NOW EASY WAY TO DEAL WITH CUSTOMER

Special to CANADIAN MACHINERY.

PITTSBURGH, June 26.—Additional ship steel fabricating work is being allotted to the Pittsburgh district. The McClintic-Marshall Construction Company is to double the capacity of its fabricating plant, the Government financing the operation, the extension to be devoted entirely to the fabrication of parts for ships. At the outset there was little work of this description given the Pittsburgh district except the large orders that have been going through the American Bridge Company's plant at Ambridge. Recently ship work was allotted to the Pressed Steel Car Company, and this is quite significant in view of the fact that this company is making a great many shells and its facilities are also desired for building cars. It is learned that this ship fabricating work is to take precedence over the building of freight cars which is not to be allowed to interfere. Another evidence of the pressure is that the McClintic-Marshall Company is also engaged to do ship fabricating work at Pottstown, in the eastern part of the State, although that is in the recently established "barred zone" which, on account of transportation limitations, is not to be given additional work except in case of special necessity.

Freight car orders recently placed are to be added to nevertheless, as it is understood that the Railroad Administration is planning to buy 40,000 cars in addition to the 100,000 recently ordered, while General Pershing has cabled additional requirements involving perhaps 10,000 or 20,000 cars.

### Demand Growing

Shipments of finished rolled steel are now at the rate of about 3,000,000 net tons a month, and a considerable part of this tonnage is going for purposes that are strictly essential although they are not the subject of Government orders. In the circumstances it is evident that the volume of direct Government orders on books or about to be placed is growing, for at the recent dinner of the American Iron and Steel Institute the Director of Steel Supplies stated that there were unfilled orders, or orders about to be placed, amounting to 16,-800,000 net tons.

Recent advices have been of about 3,-000,000 tons additional cropping out, and this week's news shows still more tonnage, the rate at which war steel requirements are growing being clearly in excess of the rate at which they are being filled, when that rate is one-half, or somewhat more than half, of 3,000,000 tons a month.

### Delivery Control Working Smoothly

The merchant blast furnaces and the steel mills have now had some experience with the new regulations promulgated by the War Industries Board by its resolutions of June 6. These prescribed a "schedule of purpose entitled to preference treatment," or in other words defined the "more essential" classes of commercial consumption of pig iron and steel products. After priority orders, etc., have been met, material is to be distributed against these purposes, and then if there is anything left, which is rarely the case, it may go to the general trade, although there are some restrictions in that matter also.

The producers report that they have been having little difficulty in interpreting and carrying out these new regulations. Virtually they replace a system of distribution which had been in force for a few weeks by the voluntary act of the producers, though without as clear a definition of the preference cases as is now furnished.

Naturally one thing that appeals strongly to the producers is the fact that when they have occasion to deny a customer any material the responsibility rests not with them but with the Washington authorities. There is a flexibility in the system, moreover, that is pleasing, in that if an issue arises between producer and customer as to whether or not a given lot of material should be furnished, as coming under the preference classification, the adjudication can be left to Washington by the producer referring the customer to the priorities division for a priority certificate. Such a certificate will be given in case the authorities approve of the purpose.

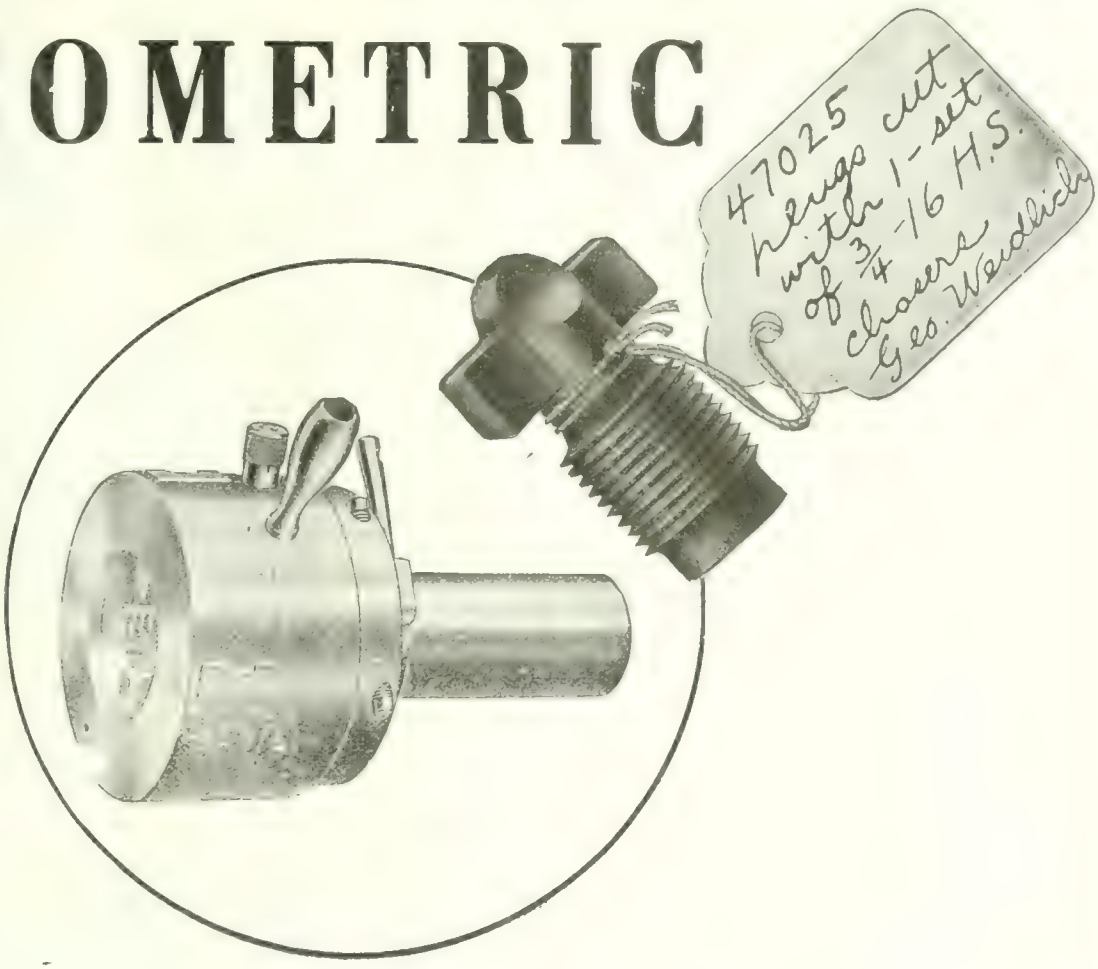
### Production

Production of pig iron and of steel ingots in June is expected to exceed slightly the rate obtaining in May, when there was an increase in pig iron over April, but a slight decrease in steel ingots. Pig iron production may be estimated at about 95 per cent. of capacity and steel ingot production at about 90 per cent., perhaps a shade more. In the case of pig iron the restriction is due chiefly to shortage of coke, though labor shortage exerts a little influence. There is practically no shortage of coke at the furnaces that are operating, but there are a few that would be blown in if coke were available. So far as the physical condition of blast furnaces goes, it has rarely been better as during the period when coke shortage was causing many furnaces to go out of blast there was extensive relining and the furnaces as a whole are in excellent condition physically. As to steel production, the restrictive influences are, in their order, scrap shortage, pig iron shortage and labor shortage. Supplies of scrap are below normal in proportion to the amount of steel being made as the current outcome of scrap is light by reason of the nature of industrial operations now being conducted and also by reason of shortage of labor for gathering and classifying scrap. The yards are receiving but little, and would hardly be able to find labor to take care of more.

Production is likely to decrease somewhat in the next two months, on account of hot weather, though as to that there were spells of weather in May as bad as any that are usually encountered in the midsummer months.

One striking thing that is being brought out is that with all the regulation as to where material is to go, and which is to take precedence of other material, there is after all little pressing demand for pig iron or steel products that is ignored. The "purposes" not named in the preference list would make a formidable showing, for normal times, involving perhaps 25 per cent. of the total consumption, but by reason of war conditions they have of late been gradually effacing themselves so that their requirements, if they were freely permitted expression, would be far below normal. No producer well acquainted with the situation can be found who places the consumption that is perforce denied at more than 10 per cent. and some place it at less. Even as to these limited requirements there may be a modicum of steel, as the months pass, though at present there is practically none.

# GEOMETRIC



## One Set of Chasers in a Geometric Die Head has cut 47,025 of these Plugs

The man who has operated the Geometric Die Head says: "In all my twenty-five years' experience I have never known a die to cut as many threads as this set has cut on cast iron."

A quarter of a century of specializing in one line has brought Geometric Thread Cutting Tools up to the high water mark.

Arrange to do your threading with a Geometric. Let our catalogue tell you about it.

## INCORPORATIONS

Incorporation has been granted to the British Colonies Transportation Co., Ltd., to build, buy, sell, equip and operate steamships, sailing ships, etc. Capital is placed at $750,000. Place of business will be St. John, N.B.

Incorporation has been granted to the Dominion Sheet Metal Corporation, Ltd. Incorporators are J. R. Marshall, H. A. Burbidge, A. B. Turner, G. A. Young, W. Hazell, all of Hamilton. Purposes of the company are to carry on the trades or businesses of rolling, tinning, galvanizing, coating and plating metals and the trade or business of iron masters, iron makers, steel makers, iron and steel converters, steel and iron rollers, colliery proprietors, coke manufacturers, miners, smelters, engineers, tin plate makers, etc., and to acquire and take over as a going concern the undertaking and all or any of the assets and liabilities of Dominion Sheet Metal Company, Limited, or all or any part of the shares or capital stock of the said company. The capital is $500,000, and place of business at Hamilton.

## MARINE

**Sarnia.**—The MacKenzie Milne & Co., Ltd., of Sarnia, have taken up the building of metallic life boats, and are making satisfactory progress in this line.

SANDWICH.—Word of the sinking in Lake Erie of the steamer Jay Gould and the foundering of the barge Commodore was brought here by the crew of the barge, four men and three women, who were picked up by the steamer Mataafa. The Gould's crew, they said, was rescued by an unidentified steamer and taken to Ashtabula, Ohio. The sinkings occurred in heavy weather off south-east shoal. The barge crew, when found by the Mataafa, were in a small boat tied to the water-logged barge.

LUNENBURG, N.S.—Miss Margaret Nicholson and other young ladies who have contracted to assist with the building of small boats, at Beinn Breagh, Baddeck, left Wednesday morning for Baddeck, where they will take up their new work at once. A number of other young ladies are already at Baddeck and others have signified their intention of taking up this work. Miss Nicholson is to remain for the duration of the war, and so are some of the others. Many have, however, contracted for one year the shortest period for which a contract will be signed, and will then renew the contract if they find that the work is congenial and that they can do it.

LONDON.—A fine piece of repair work has just been done by men of the Mercantile Drydock Company at Jarrow. A steamer torpedoed Sunday was brought to the Tyne the following day with a forty-foot rent in her side near the engine-room. Early Tuesday she was placed on the Admiralty pontoon and the men worked day and night until Friday, carrying out temporary repairs to enable her to be towed around to a wharf for completion of the work. This constitutes a record for the River Tyne. Many workmen worked for forty-three hours at a stretch, while others put in four consecutive shifts without a break.

**Halifax.**—That the work of establishing the big steel shipbuilding plant at Halifax will be commenced next week, if the engineers' plans are completed by that time, and that within three months the keels of three 10 000-ton freighters, the largest ever built in Canada, will have been laid on the building berths, was the statement made by J. W. Norcross, president of Halifax Shipyards, Limited. "Our expenditure for the shipbuilding plant," Mr. Norcross said, "will be between $3.750.000 and $4.000.000, and if the engineers have the plans ready we will start spending that money during the latter part of next week, when we will let our contracts."

TORONTO.—The car ferry Canora, which was launched at Levis, Que., is the first vessel of its kind to be equipped with a stern gate, the invention of Mr. A. Angstrom, a naval architect of this city. The ferry, which was constructed for the Canadian Northern Railway, will ply in British Columbia waters, operating between Patricia Bay and Port Mann. The stern gate is a segment of a circle. It is a new departure of the rolling type of a shutter and is arranged to completely close the stern opening when the ship is at sea. The contrivance, which closely resembles the roll-top of a desk in design, is operated by a hoisting engine situated on the cabin deck, which will raise or lower it to any distance. When up the shutter closes in on the deck in such a way that it interferes with nothing else.

**Cleveland.**—The steamer Charles R. Van Hise, of the Pittsburg Steamship Company, has been taken over by the United States Shipping Board. The steamer, now on Lake Superior, will be commandeered when she reaches Lake Erie, to be cut in two and reconstructed for salt water service. The Van Hise is the largest lake vessel taken for the coast. The steamer is 446 feet keel, 50 feet beam and 29.5 feet deep. Being too wide to pass through the Welland Canal she will be cut in two sections, which will be rolled over and towed through the canal on their sides. The Van Hise was selected because of her unusual dimensions and power. She is deeper than most lake boats of her length. She has new Scotch boilers and a quadruple expansion enginee. Her capacity is about 7,400 tons, but it is figured she will carry at least 9,000 tons on the coast.

**Montreal.**—Speaking of the Pierce McLouth, a wooden ship made at Marine City, an expert says: "The Pierce McLouth is of unusually heavy build, having six-inch bottom planking, fourteen-inch floor frames, six-inch bilge ceiling and six-inch clamps. The ship is diagonally strapped with steel, has steel straps at the head of her frames, and has two plates of seven-eighths steel, thirty inches wide, on the keelson. She is built entirely of white oak, and has an enclosed pilot house, steam steering gear, electric lights, steam windlass, patent anchors, steel spars, and, in fact, everything that would add to stability and durability. During construction all her timbers were treated with creosote. The vessel is equipped with a powerful driving outfit, having a compound engine with cylinders 24 and 48 inches in diameter and 36-inch stroke. She carries a Scotch boiler, 12 feet in diameter and 14 feet long, allowing 125 pounds of working steam pressure."

# MUNICIPAL

WELLAND.—The ratepayers of the city passed the Dillon Consolidated Steel Al... by-law by a vote of 426 to 18. The company will proceed at once with the installation of the necessary plant and early in the autumn will be employing a minimum of fifty hands.

**Montreal.**—The City Commissioners gave orders to seize the plant of Pion and Grothe when the latter declined to complete the contract for Lasalle Bridge and headgates. The city also retains a cheque of $20,000 given as a deposit. The amount of the contract was about $200,000.

**Smith's Falls.**—Speaking of the pumping plant used here, the Smith's Falls "News" says:—"The flume is on a par with the rest of the equipment of the pumping station, as an inspection of the plant proves. There are four pumps, two water-power and two steam, the former supposed to have a capacity of 2,500,000 and 800,000 gallons per day, but not pumping enough water to supply the demands of the town, which cannot be more than 1,000,000 gallons per day. The answer is that like the flume they are obsolete and ready for the scrap heap. With abundance of water power available if properly harnessed to up-to-date pumping machinery, $5,000 worth of coal is consumed in operating the steam plant to help out the other pumps with a rated capacity of over three times the possible demands of the town."

**The Canadian S K F Company, Ltd.,** 47 King Street West, Toronto, has made arrangements with the Hess-Bright Mfg. Co., Philadelphia, to be Canadian distributors for the well-known Hess-Bright ball bearings. A large stock in all sizes will be carried in Toronto and engineering designs and recommendations will be given for all classes of applications. The Hess-Bright Mfg. Co. control the Conrad patents under which other firms manufacture under license. The Conrad Patent is a method of assembly which enables a ball bearing to be made with continuous raceways, eliminating the necessity of filling sloths which rob the bearing of end thrust capacity. The "Monarch" series of bearings, of the deep groove type, are also made by the Hess-Bright Mfg. Co. These bearings are used extensively in work where heavy end thrusts are encountered such as in airplane propellers, etc.

# PERSONAL

**J. A. Burnett,** electrical engineer, Grand Trunk Railway System, has been appointed as technical assistant to the British War Mission, Washington, D.C.

The death occurred at Hamilton on Monday, June 24, of John Howard Kerr, secretary of the Canadian Westinghouse Co. The funeral took place in Pittsburg. Mr. Kerr was well known to the electrical and machinery trade in this country.

**S. A. Armstrong**, deputy minister of the Soldiers' Re-establishment Commission, it is understood, has been offered the position of general manager of the Jones Underfeed Stoker Co., of Chicago. The Chicago position is rated at $25,000 per annum.

**Frank T. Malone,** who has been representing Armstrong, Whitworth Co., of Canada, Limited, in the Hamilton district, has been appointed district representative for Ontario and has been transferred to Toronto, his headquarters in the future.

**J. S. Donal** has been temporarily assigned as manager to the Canadian Bond Hanger and Coupling Company, Alexandria, Ont., from one of the associated companies in the United States. R. J. Rose, who was the former manager, is now with the Newport News Shipbuilding Company, Newport News, Va.

**Alfred C. Roelfson,** vice-president and works manager of the Roelfson Machine Co., Galt, Ont., was married on Saturday, June 15th, to Miss Alberta McBride of Galt, daughter of William McBride, of the safe and vault department of the Goldie & McCulloch Co., Galt. After the ceremony the newly married couple left for New York and Boston.

**J. Walter Wardlaw** has been appointed general manager of the Central Vermont Railroad, with office at St. Albans, Vt. Mr. Wardlaw began his railroad career with the Grand Trunk Railway at Toronto, and is a son of Mr. T. D. Wardlaw, 62 Beaty Avenue, Toronto. Mr. Wardlaw joined the Central Vermont Railroad about 12 years ago as secretary to the general manager. He is about 35 years of age.

The marriage took place on June 14, at St. Andrew's Church, Sharrow, Sheffield, by the Rev. A. Allen, B.D., Captain George Reginald Marshall, Royal Air Force, only son of Mr. and Mrs. George Marshall, of Toronto, late of Sheffield, to Lily, eldest daughter of Mr. and Mrs. A. E. Parton, of Meadow Bank House, Sheffield. Mr. George Marshall, of Toronto, father of the groom, is resident agent for Wm. Atkins & Co., Sheffield.

In the death of Captain Archibald Reid, of Montreal, the shipping fraternity of Montreal loses one of its best known figures. Though born in Liverpool, practically the whole of Capt. Reid's active career has been spent either in Montreal or on sea voyages which had Montreal as their destination or port of departure whenever navigation was open. He was 72 years old. For a quarter of a century he had been port warden at Montreal, and concurrently until last year Lloyd's surveyor as well. Before that he was for many years superintendent on the port for the Dominion Steamship Company, and previous to that again he had commanded the steamship Dominion and other liners of the company which came to Montreal in the summer and to Portland in the winter.

# TENDERS

**Winnipeg.**—Tenders are being asked for the supply of glassware and electrodes for the city street lighting de-

partment. The last date is July 5. Instructions at 54 King street. M. Peterson, Board of Control office, is secretary.

**Toronto.**—Tenders will be received until 12 o'clock noon, on Tuesday, July 2, 1918, for the construction of a military garage at Toronto, Ont. Plans and specification can be seen and forms of tender obtained at the offices of the chief architect, Department of Public Works, Ottawa, and the Clerk of Works, Postal Station "F," Toronto, Ont.

**Kingston.**—Tenders will be received up to June 28 for the construction of a military Isolation Hospital at Kingston. Plans and specification can be seen and forms of tender obtained at the offices of the chief architect, Department of Public Works, Ottawa; Power & Son, architects, Kingston; the clerk of works, Postal Station "F," Toronto, and the overseer of Dominion Buildings, Central Post Office, Montreal, P.Q.

**Winnipeg.**—Tenders will be received until 12 o'clock noon on Wednesday, July 10, 1918, for the construction of a stop log dam, pile bridges and canal for the diversion of the Little Pembina River into Lake Pelican, Souris County, Manitoba. Plans and forms of contract can be seen and specification and forms of tender obtained at this Department at the office of the District Engineer at Winnipeg, Man., and at the Post Office at Ninette, Souris County, Man.

**Winnipeg.**—Tenders, addressed to the Chairman, Board of Control, will be received up to 10 a.m. on Tuesday, July 2nd, 1918, for the supply, delivery and erection in the Winnipeg General Hospital power house of one 200 k.w. motor generator set, together with certain switchboards. Instructions to bidders, together with specifications and forms of tender, may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, secretary, Board of Control office, Winnipeg.

**Windsor.**—Sealed proposals will be received by the Essex Border Utilities Commission at the office of Morris Knowles, Ltd., engineers, 8 Royal Bank Building, Windsor, Ont., until twelve o'clock noon, July 8, 1918, where they will immediately thereafter be publicly opened and read, for the construction of the east sewerage interceptor and appurtenances. The work includes furnishing all the material and doing all the work for about 1,060 feet of 15" vitrified pipe sewer, 1,310 feet of 18" vitrified pipe sewer, 1,530 feet of 20" vitrified pipe sewer, 2,540 feet of 24" vitrified pipe sewer, 1,960 feet of 27" vitrified pipe sewer, 3,640 feet of 33" vitrified pipe sewer, 49 manholes, 2 measuring chambers, 3 regulating chambers.

[illegible] The output is now approximately [illegible] feet per month.

**Factories Closing.** Two hundred small factories in the Chicago district have been forced to close by reason of the order withholding steel from concerns not engaged in Government work. This statement was given out by the Illinois Manufacturers' Association to-day.

**Short of Power.** The rationing of power had to be resorted to again at Galt on account of there being insufficient Hydro to meet the local demands. One circuit was cut out one day and another the following day. Local officials say the rationing may have to continue for several days.

**Winnipeg.**—The Theodore Kipp Co., Ltd., having purchased the business of the Mechanical Engineering and Manufacturing Co., have been granted letters of patent, changing the name of the company to Kipp, Kelly, Brown, Limited. All business in future passes under that name.

W. H. PLEWES

A member of the firm of Plewes, Ltd., manufacturers' agents, Winnipeg, returned home last week, having been wounded in France. Mr. Plewes joined the Cycle Corps in 1915, and left Canada in 1915 for Europe. He went through several severe engagements, including Passchendale, and was twice sent to hospital for treatment. Mr. Plewes was with the Northern Electric Co. for two years, later with the Canada Metal Co., entering his father's business in 1914, but left the following year for France.

**Surrender Charter.**—Notice appears in the papers that an application will be made to the Lieutenant-Governor of the Province of Ontario for an order accepting the surrender of the charter of Canadian Munitions Corporation, Limited, under the Ontario Companies' Act, Revised Statutes of Ontario, 1914, Chapter 178, and amendments.

**Men Wanted.**—Large advertising space is still used in connection with the attempts of munitions firms to get men enough to carry on their work. There has been a departure from the condensed ad. calling for help. In its place factories are using big display spaces. For instance, the Canada Bridge Co., of Walkerville, Ont., use 24 inches of space in the Wallaceburg "Herald" to try and secure untrained men for munitions work.

**Labor Conditions.** — The following statement was issued by the Labor Department:—"There is an apparent misapprehension as to the extent of labor troubles in Canada. Canada is still, by comparison with other countries, extremely favored in these matters. At the present time, from Cape Breton to Vancouver Island, there are no more than five or six trifling strikes, most of them about a week old, and involving in all something less than 250 men and women. None of them are of more than local interest or importance."

**Change of Address.**—Announcement is made of change in address of the Crane Packing Company's New York office to larger quarters in the Park Row Building, and the appointment of Julian N. Walton, manager. A. W. Payne, connected for some time as manager of this district, has been made sales manager of the United States and Canada, with headquarters at the home office in Chicago. The Pittsburgh offices are located in the May Building, Pittsburgh. The Philadelphia office in the Colonial Trust Building.

**Becoming Scarce.**—A Montreal firm is advising its customers as follows this week: "It is becoming more difficult to secure supplies of citric and tartaric acid, and particularly tartaric, English manufacturers have been and are still unable to offer tartaric for any shipment, and we understand that Italian makers are also refusing to quote. Indications point to a severe shortage and we think it would be well for our friends to look into their requirements without delay and endeavor to pick up anything which might be available from stocks in Canada."

Canadian Hoskins, Limited, Walkerville, manufacturers of electric furnaces and pyrometers, are erecting a concrete and steel factory building on Walker Road, which they hope to occupy within three months. It is an L-shaped structure, 60 x 170 x 220, and will give the company the requisite facilities for the production, not only of their regular lines, such as pyrometers and furnaces, but of nickel chrome castings and wire in which they are specializing. The new factory will call for a much larger working force, and it is worthy of note that the company speedily outgrew the quarters in the Walker industrial building which they occupied about two years ago.

**Russian Rails.**—Much has been said about a quantity of steel lying at Vancouver on order for the Russian Government. An Ottawa explanation is that "the large quantity of Russian rails reported to be rusting on docks in British Columbia have for some time been the subject of negotiations by the Dominion Government looking to their purchase. The Government is quite pre-

pared to buy the rails, but the difficulty arises from the fact that conditions in Russia are so unsettled that they are not able to find any authority with whom there can be conclusive negotiations. There is sufficient steel to span 150 miles. The Government may also buy four thousand box cars consigned to Russia, but as they are extra broad gauge they would be of little use save as scrap to be rebuilt."

**Plants Tied Up.**—Strikes and threats of strikes in factories engaged in the manufacture of important war materials have tied up production in several plants of greater New York. Most of the plants affected have been working on sub-contracts, making parts for the Liberty motor. The factories tied up by strikes are: Scientific Machine and Tool Corporation, 57 Jay street, Brooklyn, making fixtures for Liberty motors. Chatham Machine and Tool Company, 128 Mott street, working on Liberty motor sub-contracts. Premier Snap Fastener Company, 182 Grand street, making Liberty motor and aeroplane parts. Premier Special Machine and Tool Corporation, 421 Canal street. National Indicator Company, 852 Vernon avenue, Long Island City, Liberty motor sub-contractors. Blair Tool and Machine Works, Inc., 521 Greenwich street, making parts for motor trucks awaiting shipment to France.

**Builders in Convention.**—Seventy-five delegates attending the annual convention of the Provincial Builders' and Supplies' Association at Galt were given a civic welcome by Mayor Dakin. The following are the officers:—President, A. Tomlinson, Chatham; first vice-president, Lt.-Col. G. Youngs, Stratford; second vice-president, Robt. Elgie, Toronto; secretary-treasurer, T. R. Wright, London; executive, G. A. Robb, Galt; J. S. Adamson, Ottawa; A. Hannaford, Hamilton; J. Morton, Sarnia; E. Blondie, Chatham; R. Masson, Stratford; F. Nicholson, St. Catharines; S. Willis, London; G. Stocker, Toronto; G. J. Oakley, Toronto; auditors, D. Davidge, Toronto; E. Gerry, London. Robert Elgie, of Toronto, gave an address emphasizing the benefits of patronizing home industry, and it was decided to memorialize the Federal Government to regulate the operations of foreign contractors doing work in Canada. A report was read by G. Gandier, of Toronto, on the benefits of the Workmen's Compensation Act.

## CATALOGUES

**The Canadian S. K. F. Company Ltd.**, 47 King Street West, Toronto, is now carrying a stock of chrome alloy steel balls in all sizes ready for immediate shipment. These balls, which are hardened clear through, are suitable for the highest class of work and heavy service. They are guaranteed round and true to size within one-ten-thousandth of an inch.

**Pocket Catalogue of Young Ovens** is the title of a new catalogue D describing model "G" ovens for japanning, enamel-

Scandinavia Belting
Is a Good Belt for Dusty Places

In cement plants and in [illegible] where there is lots of dust this belt is producing results that are very satisfactory for the mill operators.

You know how wearing grit is on a belt, and you want a belt that will not come apart when only partly worn through.

"Scandinavia" is this kind of a belt there are no plies to come apart—it is solid woven. We have seen these belts still giving good service when the thickness was half worn through, and on the pulley side of the belt there were no frayed ends the surface of the belt was smooth.

Mr. Plant Manager, you know what this means. If you require a belt for operating in a dusty place, let us ship you one, [illegible]

Federal Engineering Co., Limited
172 John Street, Toronto

Note—Do not use "bar" or "stick" belt dressing on textile belts.

METAL STAMPINGS

We are manufacturers of stamped parts for other manufacturers.

We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.

We can finish steel stamping in Nickel, Brass or Copper.

Send us a sample order.

(i.e., drying and core baking, etc., made by Young Brothers Co., Detroit, Mich. The catalogue contains brief general information covering the various types of ovens, describing the principal features and illustrating a number of typical installations.

**Electrical Equipment.**—The Ward Leonard Electrical Co., Mount Vernon, N.Y., has issued a pocket size loose leaf bulletin covering an interesting line of electrical equipment such as rheostats, controllers, resistance units, etc. The bulletin contains temporary price and data sheets covering only the apparatus upon which the company can offer reliable delivery dates and assure maintenance of prices. The reason being that the company's facilities are now largely devoted to Government work affecting regular production in the meantime.

**The Present Day Applications of Ball Bearings** is the title of an interesting bulletin being distributed by the Canadian S F K Co., Toronto, principally among colleges and larger educational institutions. This bulletin is gotten up in the form of an illustrated lecture and the company has prepared sets of lantern slides to accompany the lecture for the purpose of creating interest in one of the latest developments in mechanical appliances and showing the latest applications of ball bearings. The lectures and slides are sent out to universities and colleges for the benefit of the students and others who may be interested in mechanical matters. In addition to illustrating and describing the various applications, the bulletin also contains a brief history tracing the development of ball bearings. It deals with the principal features in the design and construction of the S K F ball bearing and describes how ball bearings are manufactured. The applications described cover a large number of industries including automobiles, machine tools, textile, tractors, paper making, milling, wood working, etc. Copies of the bulletin may be had on application by any student, mechanic or engineer interested in the subject. For copies apply to the Canadian S K F Co., 47 King Street West, Toronto.

## BOOK REVIEW

**A Study of the Heat Transmission of Building Materials.**—An investigation to determine the coefficients of heat transmission of standard building materials for exterior walls has been completed by the Engineering Experiment Station of the University of Illinois under the direction of A. C. Willard, Professor of Heating and Ventilation, and L. C. Lichty, Research Fellow. The tests were conducted according to the so-called "hot air box" method, the boxes being built of the material to be tested and of such a size as to insure conditions similar to those found in actual practice. The heating was done electrically so that the input of heat could be controlled and accurately measured. The materials tested included various sizes of tile plastered, magnesia board, cork board, wood, concrete, brick, glass with and without an air space, sheet asbestos and asbestos board. The degree to which the transmission coefficients of the various materials are affected by variations in air velocity, by humidity, and by the use of air spaces in wall is discussed, and the results of the tests are given in detail in Bulletin 102 of the Engineering Experiment Station. The publication is illustrated with diagrams and photographs of the apparatus. Copies of Bulletin 102 may be had gratis by addressing the Engineering Experiment Station, Urbana, Illinois.

**Fuel Economy in the Operation of Hand-Fired Power Plants.**—The scarcity of coal last winter and the recent warnings of the fuel administration regarding the possibility of a shortage next winter emphasize the need for greater economy in the use of fuel. The present high rate of production is still insufficient to supply all needs and there seems to be no possibility of an increase in the output of the mines to meet demands.

There are two possible results of this fuel shortage; either certain industries must close down or more work must be done with the coal available. The Engineering Experiment Station of the University of Illinois has just issued a 90-page booklet printed in four colors which shows that the average small power plant can save fifteen per cent. of its fuel by the exercise of greater care in equipment and operation. This means a saving of 12 or 13 million tons per annum if applied throughout the country.

The purpose of the publication, the title of which is "Fuel Economy in the Operation of Hand-Fired Power Plants," is to present to owners, managers, superintendents, engineers and firemen, certain suggestions which will help them in effecting greater fuel economy, and in determining the properties and characteristics of the coal purchased. Features of installation essential to the proper combustion of fuel are discussed, the practise to be observed in the operation of the plant is outlined.

The publication was prepared by a special committee of the research staff of the Engineering Experiment Station assisted by an advisory committee consisting of Joseph Harrington, advisory engineer on Power Plant Design and Operation, Chicago; Arthur L. Rice, editor "Power Plant Engineering," Chicago; John C. White, chairman educational committee, National Association of Stationary Engineers, Madison, Wis.; O. P. Hood, chief mechanical engineer, Bureau of Mines, Washington, D.C.; D. M. Myers, advisory engineer on fuel conservation, United States Fuel Administration, Washington, D.C., and C. R. Richards, Dean of the College of Engineering and director of the Engineering Experiment Station of the University of Illinois.

Only a limited supply of copies of this publication is available for free distribution. Requests for copies should be directed to the Engineering Experiment Station, Urbana, Illinois, and should specify "Circular No. 7."

# Government May Stop Construction of Eaton's Vast New Mail Order Building

MILLIONS of dollars—$3,500,000 to be exact—is the estimated cost of the huge new mail order building projected by the T. Eaton Company in Toronto. The structure, 400 x 330 feet in foundation area, is to have over a million feet of floor-space, and would be, if constructed according to present plans, the largest single building ever planned in Canada. It has been designed, according to report, solely to enable the T. Eaton Co. to meet the immense mail order competition of the Robert Simpson Company through their big modern mail order building on Mutual Street, Toronto. Or, it may be simply a necessary step due to the immense development of Eaton's own mail order business. Anyway estimates have been called for the structure, and to-day the question is: "Will the Government allow the building to go up?"

## Steel and Labor Seriously Involved

Already the Dominion Bridge Company are preparing to roll the steel for the structure. Steel is a precious munition of war to-day. Labor is looking for employment at the highest possible wage-rate and enterprises both patriotic and profit-earning are looking far and wide for labor. So serious is the farm-labor situation likely to become that the Government instituted National Registration and the Registration Cards lay emphasis on farm-work. Will the Government permit the construction of a building which will use enormous amounts of steel, and tax supplies of labor to a great extent?

## The Financial Post Deals With This Question and With Others

In THE FINANCIAL POST of June 22nd you will find this question very keenly analyzed. You are interested. Every merchant or business man in Canada is interested. THE POST goes incisively into vital matters that concern business in Canada, the business affairs that bring you money. Here are headlines from the issue of June 22nd. Each one of them indicates a business feature of the week, the information on which will be valuable to you, and all the contents of THE POST are not given by any means. Just note these:—

Housing—A Live Subject Throughout Dominion.
Pooling of United States and Canadian War Resources.
Conservation of Coal Needed to Avert Fuel Famine.
Sir Thomas White May Succeed in Getting U. S. Credit.
Fire Insurance Men Criticise the C.M.A. Report.
British Industry Asks Protection From Competition.
Closing Down is no Calamity For Flour Mills.
Senator Nicholls' Trade Corporation Idea.
Supplementing Manufacturers' Balance Sheets For Banks.
Victory Loan Conference on Tuesday.
Over-Favorable Crop Reports Are Unwise.
Bank Profits and Stocks Now, and Before War.
Bank Clearings Again Fall off in West.
Edmonton Getting Back to Equilibrium.
New Westminster Received Bids For Bond Issue.
Thyssen—The German Capitalist Who Was to Own Canada.
Peddlers of U.S. War Orders Getting Middle Profits.

These headlines, and the other important contents of THE POST will indicate to you most important business news matter. To read THE POST on these subjects and on each week's business affairs of note as they arise will provide you with facts to make your opinions in conversation with other business men strong in constructive idea and suggestion force. Careful consideration of THE POST will prove to you its practical value. Secure subscription to-day by signing and mailing this coupon.

# A MAN

was wanted as Tool-room Foreman. He was found by a condensed ad. in

CANADIAN MACHINERY
*Classified Advertising Section*
143-153 University Ave., Toronto

*consult our Buyers' Directory and write advertisers listed under proper heading.*

# *Mr. MacAloney goes us one better!*

IN the June 13th issue we ran an ad on page 71 headed "When you're looking for a job, what do you do?" We suggested that you might wait for a friend to "put you wise" or inquire at different plants, but would probably look over the "Help Wanted" columns of the first paper you picked up and get your job by answering one of the ads.

And we told you why only the good jobs are offered in CANADIAN MACHINERY and why—but that's another advertisement. We started to tell about Mr. H. T. MacAloney, works superintendent of a large Ontario plant. Our ad recalled to him the last time he was looking for a job, on which occasion CANADIAN MACHINERY played a prominent part, so he wrote us about it.

"What you say is all right so far as it goes," he says. "But it doesn't go far enough. When I was looking for a job three years ago, I asked friends, answered ads and inquired at different plants just like you say in your ad. But I went you one better—I advertised for a job, in CANADIAN MACHINERY, and got one—the job I have now.

When a man knows he's a good workman and isn't going ahead, *then* is the time to advertise for something better. Most men don't seem to realize that to a prospective employer this indicates confidence in their ability to make good and shows them to be progressive and up to the minute. It's a pity more don't think of this because many of them are losing opportunities galore to better their positions."

We leave Mr. MacAloney's suggestion with you. And we recommend our Classified Advertising Section if you decide to adopt it. It's the only place your advertisement will be effective. CANADIAN MACHINERY is read in shops all over Canada by the men you will want to interest and the Classified Advertising Section is followed closely by the majority of them.

Our rates are low—two cents a word for first insertion and one cent a word for subsequent insertions, minimum order $1.00. Send us your ad to-day—if you prefer, give us the particulars and we'll be glad to write it for you.

HARTFORD, CONN., U.S.A.

# Lowering the Cost of Getting Orders

THEY were talking about the high cost of getting orders—were Brown and Jones. They were agreed on some things: train service was interfering with ability of salesmen to call on as many as formerly; hotel bills were adding heavily to the weekly expenses of salesmen; congested freight and express service was interfering with quick deliveries; salaries of men were going up; labor of all sorts, as well as materials, was becoming higher-priced.

Then Brown said: "I am giving a good deal of thought to the training of my salesmen. I am endeavoring to save them needless waste of time—to sell more goods, and to reduce the number of futile calls. I notice that they are giving much attention to this subject in the United States, and that in Canada some firms are paying serious attention to this matter of better salesmanship."

"What are you doing?" said Jones.

"Well, I haven't got far as yet, for I am in the initial stages of my studies. But one thing I have learned: it is that my men haven't been analyzing the causes of their failures to make sales. I can't blame them, for I myself haven't troubled myself to dig into this phase of the selling game. Now I [illegible] Why the failure to get the order?

"I have discovered a good deal. One thing is that my men haven't known enough about the goods they took out to demonstrate them convincingly. This is largely our fault. So we are using time and printed matter to make our men know exactly what they have to offer.

"Another thing we have had impressed on us is that our men haven't been approaching their prospects always in the best way. They have been too keen to sell rather than to serve.

"I saw a thing the other day that is good—by a man named Casson. He said the average salesman's method was 'Talk—Argue—Compel.' As against this, he recommended: Listen—Argue—[illegible]

"What he means is that the salesman must get on the side of the buyer if he is to have best results. And so I am doing something to get my men trained to acquire the point of view of the man they canvass—this first. When a salesman postpones his sales talk until he has won the interest and attention of the prospect, he is in a much more favorable position to put across his proposal.

"I read recently an advertisement of the FINANCIAL POST in which it told of Frank Mutton, President of the International Business Machines Company, in which he said that he has subscribed to THE POST for each of his salesmen in order that they may be well informed about business conditions and affairs in Canada—this as an aid in making sales. The idea, I infer, is to make his men quick to get the point of view of the men they are to canvass—to become possessed of a kind and amount of information which will enable them to make themselves interesting to prospective buyers of time-recording machines.

"Now, I have known Mutton for many years—known him to be a super-salesman. In subscribing to THE POST for his salesmen, I saw one of his methods—secrets, if you like. So I got THE POST myself to see how my men could make use of it for the same objects.

"I have subscribed to THE POST for 4 months at the cost of a dollar per salesman, and I have been having my men report to me in writing just how they are finding THE POST useful to them. They read THE POST with one question uppermost: What item or article in this issue can be used by me to help me make sales?

"I want to tell you, Jones, that I am delighted with the experiment. The minds of my men have been stimulated. They are 'cashing in' on what they read. They relate certain items or articles to certain prospects, and they are approaching their customers with greater confidence, greater art, and with more persistency, born of a surer knowledge of how our product is worth the other man's consideration and purchase.

"My men are bringing in more business, and this offsets the increasing costs of going after business."

* * * *

A VERY suggestive conversation, is it not? The point of its reproduction here: If you think the idea put into operation by Brown (and Mutton who is paying for 50 subscriptions for men in his employ) is worth your consideration, then investigate THE POST for yourself. Instruct us to send THE POST to you that you may investigate it from the angle—What is there in this paper that my men can use to help them "get next" their prospects with a view to making more sales and in quicker time?

So we suggest to you that you sign the coupon below.

Just what does THE FINANCIAL POST aim to do? The answer is: It gives business men information about every important happening in every part of Canada as this happening relates to Business. It follows the various listed and unlisted securities, and gives each week clear and accurate and up-to-the-minute information about them. It tells about the movements and influences affecting such groups of investment interests as Iron and Steel, Textiles, Milling, Pulp and Paper, Transportation, and so on. It has numerous contributed articles of first-class interest and importance. It contains much personal matter—notes and sketches about men of influence or position in the public eye whose doings or sayings have relation to Business. What's more, THE POST is extremely readable. It is edited and prepared by trained journalists—the highest-priced staff of men on any publication in Canada. All this makes THE POST a "different" paper, and a good one. The subscription price is $3.00 (52 issues — Saturdays); or 4 months for one dollar.

---

The MacLean Publishing Company, Ltd.,
143-153 University Avenue, Toronto.

Send me THE FINANCIAL POST (weekly, every Saturday). Subscription price of $3 will be remitted on receipt of invoice in the usual way. Have it addressed to

# Flint Shotting Saves Machining Cost

In **two** ways:

1. By Flint Shotting CASTINGS or FORGINGS, so much of the fins and unevennesses can be removed **by wholesale** that the subsequent machining is reduced to the minimum.

2. By Flint Shotting Hot Rolled Stock or Heat-treated Forgings the mill scale and furnace scale—both ruinous to tools—are removed, and the life of breaking-down tools, milling cutters, etc., multiplied. At the same time the **output** per man per day is increased—even doubled.

Flint Shotting has been called "sand blasting with a college education"—because Flint Shot is a precise, accurate, uniform, scientifically-produced form of sand blast "sand."

Note the "quotes" around the word "sand"—because Flint Shot is really not sand at all, but a **manufactured** product, secured by disintegrating St. Peter's Rock and segregating, washing, drying and screening the pearl-like nodules of **pure flint** contained in the rock.

The fact that one car of Flint Shot lasts as long and does as much sand blasting work as two or three cars of natural sand is of peculiar interest just now, no matter how far you may be from our big plants at Ottawa, Illinois.

We can load your car immediately.

Envelope sample and quotation will echo your telegram, instanter.

## United States Silica Company

**Sole Producers of Flint Shot** **430 Peoples Gas Bldg., Chicago**

# The Cost of Labour and Material

makes it more than ever necessary to get value for costs.

You will find, for instance, that it is more economical to have a mechanic turn in a file that has passed its "efficient" point, than have him use double the time on a job because of a dull file.

Also, remember, when buying files, to specify "Famous Five." They are well balanced and stay hard and sharp because they are accurately cut and properly hardened.

They are:

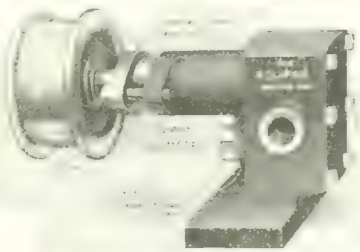
20 -($4.86) 27/-($6.56) 34'-($8.26)

Cash; Ex-Works.

All with Relief Valves.



Unquestionably a high grade Pump at a **low price.**

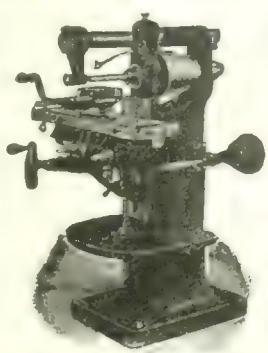
Fitted with **Gunmetal Wheels, Bush and Glands** at the price of Steel Wheels and C.I. Glands.

**Will prove superior to any Pump with Steel Wheels and C.I. Glands, &c.**

*AGENTS WANTED*

**FRY'S (London) LIMITED,** HEAD OFFICE: 46, UPPER THAMES STREET, LONDON, E.C. 4.
WORKS: GREENWICH, S.E. 10

# Increased Production Means Increased Profits



Large Millers for large work —STEPTOE MILLERS for small work

Large Planers for large work —STEPTOE SHAPERS for small work.

**Will result in increased production; less money invested in machinery, and increased profits.**

**THE JOHN STEPTOE COMPANY**
**CUMMINSVILLE, CINCINNATI, OHIO, U.S.A**
Canadian Representatives: Garlock-Walker Machinery Co., Toronto, Ont.

# Fearless and Entertaining

This is the most momentous time in history, and you want your reading to keep you abreast of what is happening in the world. You want articles that are timely, vital, fearless. Here's what is offered in June MACLEAN'S:

**Must the British Empire Cease to Exist?** Must all nations as strong as Britain's collapse or exist? Read what is said on this subject by - - - - - - **H. G. Wells**

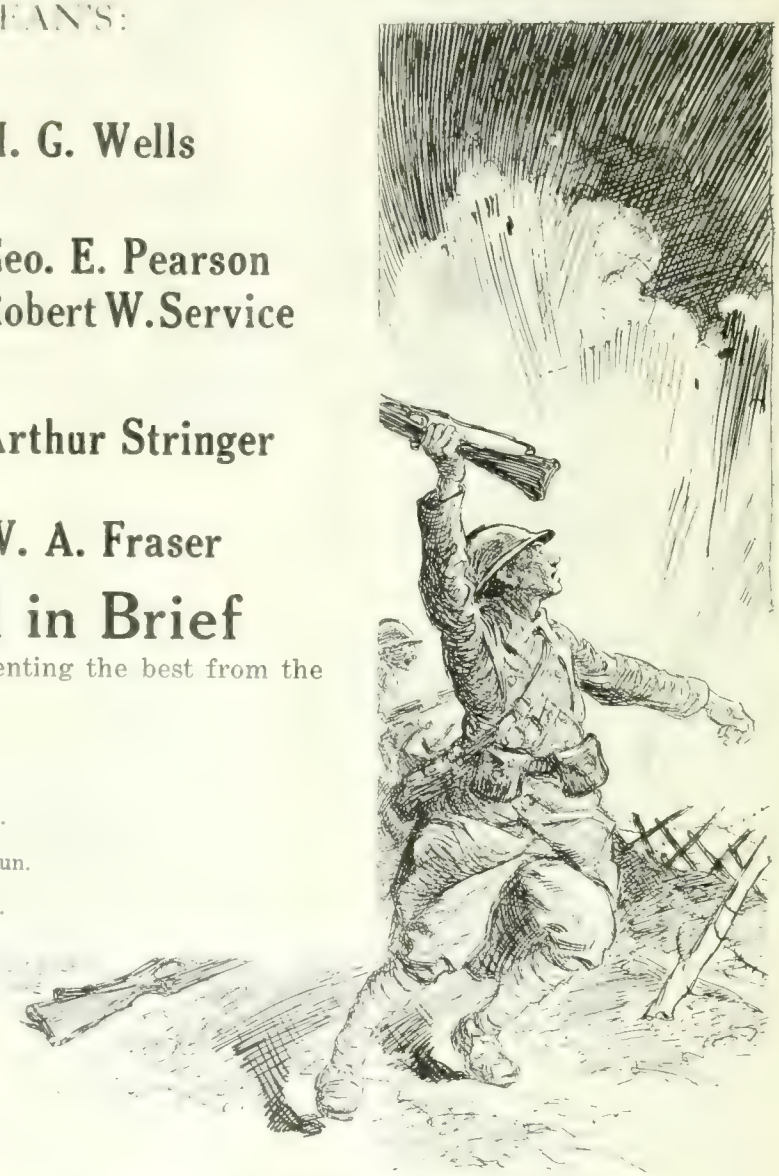
**When a thousand guns play on a single trench,** what happens in that trench? A powerful description by one who lived through it by - - - - - - **Geo. E. Pearson**

A soul-stirring ballad of the trenches by **Robert W. Service**

**Galvanizing the Government at Ottawa.** An article on the work of the Ginger Group.

A gripping mystery story by - - - **Arthur Stringer**

**The Three Sapphires**—A new serial story combining Hindu mystery and war intrigue by a great Canadian novelist. **W. A. Fraser**



## News of the World in Brief

The following articles are reprinted as representing the best from the best magazines the world over:

Is This Germany's Plan?
Is Japan Seeking a New Ally?
How Allied Victory Was Lost.
Is Foch Another Napoleon?
How Germany Annexed Turkey.
The Death of General Maude.
That Mysterious Long Range Gun.
How Bolo Pasha Was Caught.
The World is Growing Warmer.
Super-Kaiser or Little Willie?

# JUNE MACLEAN'S

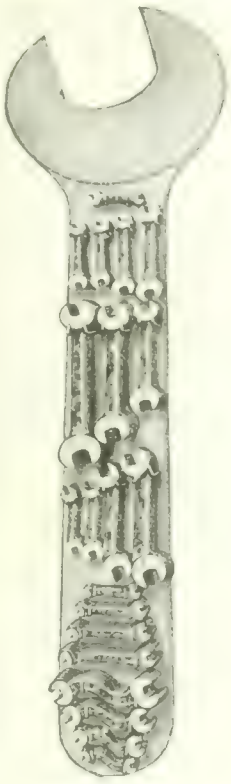
At All News Stands - 20c.



Display Board

## This is No Free Offer of

# Williams' Superior Drop-Forged Wrenches

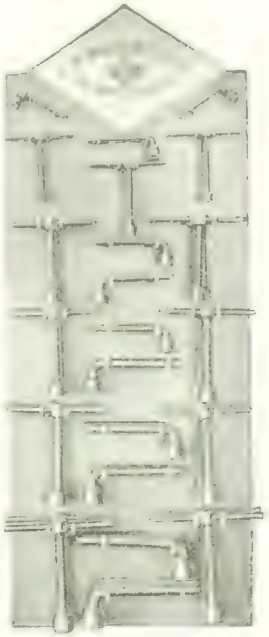
It is but another evidence of J. H. Williams & Co.'s policy to make your display and sale of Williams' Wrenches attractive and profitable. We shall be well paid for the board in the increased business we acquire through your use of it, and in the added satisfaction it affords you and your trade.

### You Buy the Wrenches

a carefully selected assortment that provides the widest range of usefulness. Their finish and physical qualities are unexcelled; and they enjoy a larger consumer demand among mechanics than all others combined.

We have additional Display Boards fully described in our "Silent Salesman" Booklet; it's free, with your imprint, if desired.

**Western Office and Warehouse:**
**45 South Clinton Street, Chicago**



Socket Wrench
3 Wrenches each size

# There's a man

advertising on page 70 for a position.

Have you a position open that he could profitably fill? If you have, write him. If you have the position and don't think he can fill it, advertise for one who can.

**Canadian Machinery**

*Classified Advertising Section*

143 University Avenue, Toronto

# Let them know it's there

In commenting upon the results secured from their advertisement in the classified section, one advertiser said:

> "Of course we would not have sold it without letting people know it was here, that is obvious, and thanks are due you for letting the people know it was for sale."

If you have any old or used equipment for sale, let people know it's there. Your message in Canadian Machinery will be placed before the probable buyers of such equipment.

**Canadian Machinery**

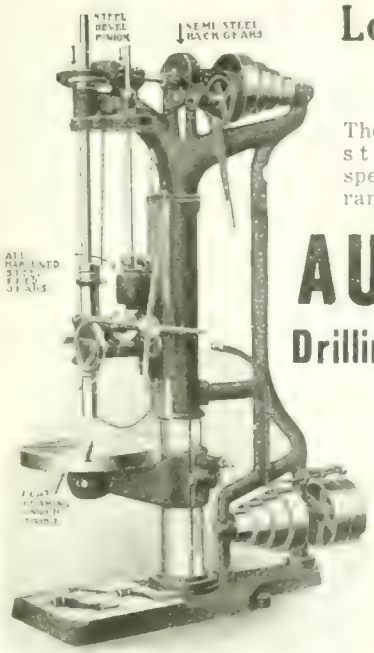
## Production of Rare Quality at Lowest Labor Costs



There is unusual strength, accuracy, speed, convenience and range in

# AURORA

## Drilling Machines

You can use them to great advantage on HIGH EXPLOSIVE SHELLS or any work in your shop that's suitable for a machine tool of this kind. The operating is easy and the labor cost comparatively low.

**Drop a line for full particulars and specifications.**

Stationary Head Sizes 20″—21″
Sliding Head Sizes 22″—44″

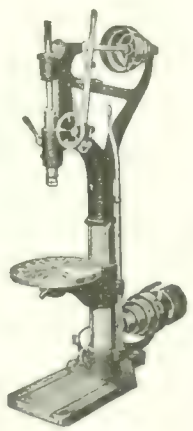
## The Aurora Tool Works

AURORA, INDIANA, U.S.A.

---

## The BARNES DRILLS

TRADE B MARK



Complete line. 8-inch to 50-inch swing

**Gang Drills.—Horizontal Drills.**

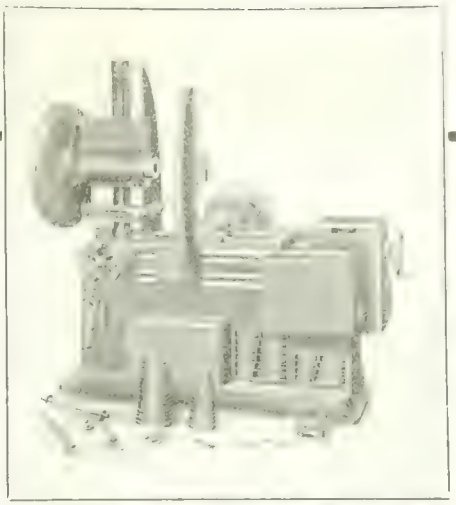
B & S No. 4



SPUR GEAR-CUTTING MACHINE

## Rapid as Well as Accurate Spacing of Gear Teeth

made possible by the positive nose-back independent [illegible] & Sharpe Gear Cutting Machines

### Accuracy is assured by:

### And a High Production Rate because:

Both [illegible] of B. & S. Machines shown here have the improving mechanism described [illegible] above, besides many other features [illegible] make them the ideal machines for the busy shop. Send for literature covering all features in detail.

# SMOOTH-ON

TRADE MARK-REG.U.S. PAT.OFF.

## Iron Cements

Positively stop all leaks of steam, water, fire or oil in iron or steel. Unequalled for smoothing over rough and defective castings.

Smooth-On Cements are easy to apply, harden quickly and make permanent repairs.

**Every Engineer should have a copy of our new illustrated instruction book. It is free.**

*Smooth-On Iron Cements are sold by supply houses.*

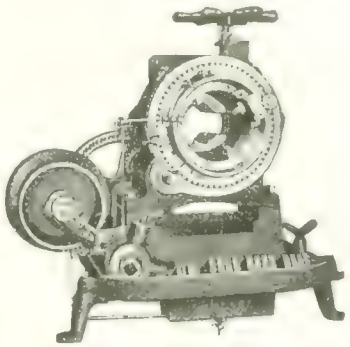
Smooth-On Mfg. Co.

JERSEY CITY, N.J. U.S.A.

**Send for New No16 Illustrated Instruction Book**

# No Leaky Joints

when the Forbes does the threading



FORBES Pipe Cutter and Threader is the machine you want right to cut and thread large pipe. It does the work quickly and accurately. Send for catalog of 1 and 2 inch cut, steam and die machine.

The Forbes is the only machine equipped with roller rests, carrying the die on to the pipe and is fully adjustable, to compensate for wear. And instead of turning the heavy weight of pipe in the die, as is usual, it turns the comparatively light die around the pipe.

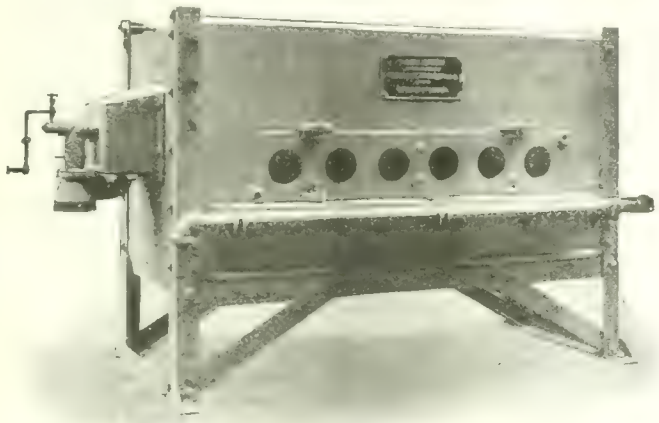
# Is control of temperature on the instant an advantage?

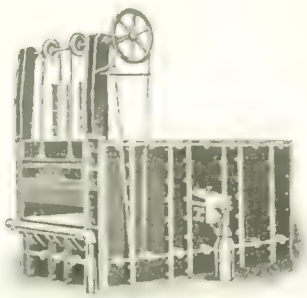
Is it any advantage to bring a furnace up to required heat in less time and with less fuel and to be able to shut off the supply of fuel the minute work is done?

Is it any advantage to have a workshop without smoke and soot, without chimneys and flues, without coal and ash piles?

Is it any advantage to save space and the wages of stokers?

If it is—





*At half the first cost of a coal-burning furnace,* own any one of the

# "Mecol" Oil-burning Furnaces

and experience all the advantages they possess.

Mecol Furnaces are used in several of the largest plants in Canada—in many small plants, too.

TYPE C-2

# The Right Furnace For Every Purpose

THE types shown are only two of over one hundred types and sizes of Gilbert & Barker Furnaces—a furnace for every purpose.

G. & B. Furnaces are built right. Their construction and design have been perfected by our half century of experience.

We offer you the benefit of this experience and thorough knowledge of modern heat-treating methods through our engineering department. The service is free. Put your problems up to us.

Just now we are making prompt delivery of these two types and many others. Send for Stock List 24.

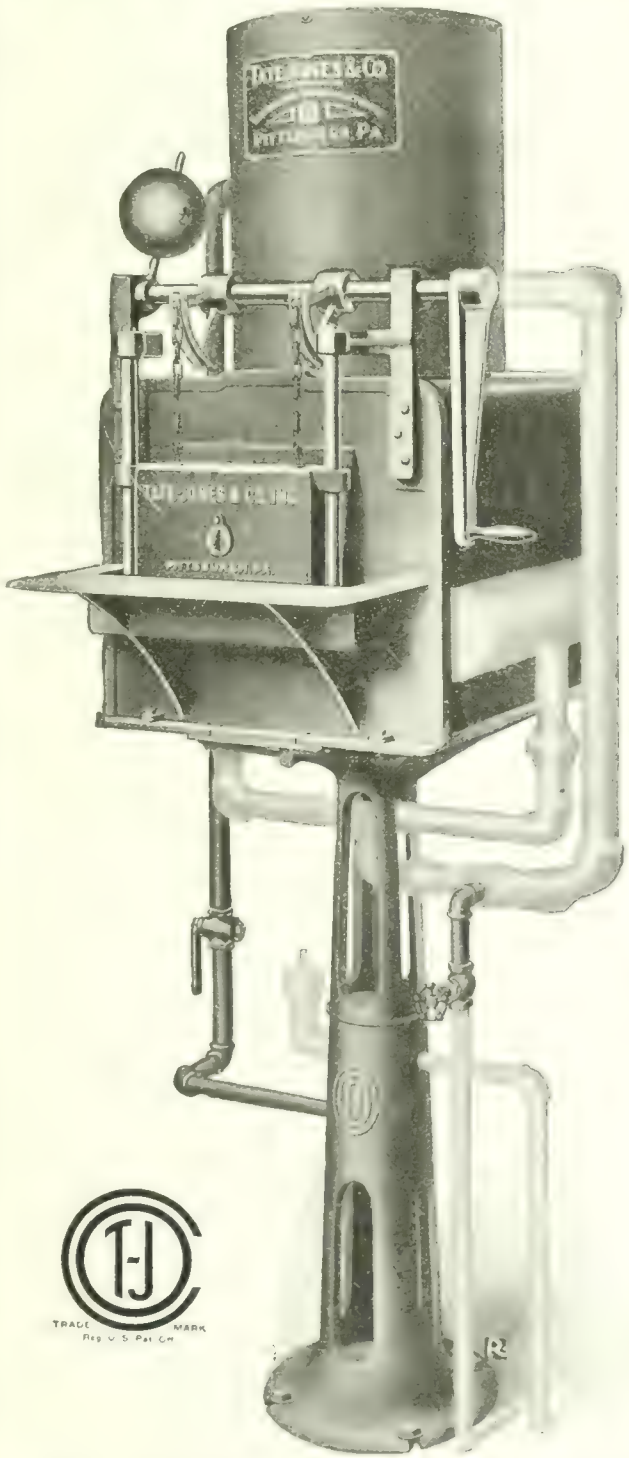
# HIGH-SPEED STEEL



To aim at anything less in this day of super-effort is little short of a calamity. Industry cannot afford to take chances. You will eliminate "chance" if you heat your high-speed steel in a

## Tate-Jones Series H Gas Oven Furnace

For temperatures, 1600° to 2400° Fahr. Uses either artificial or natural gas with air at 1½ to 2½ pounds pressure. Radiation loss is exceedingly small, while the recuperative feature effects a saving in fuel of 25% in ordinary work.

This furnace is intended for use in the tool room or for manufacturing uses where it is necessary to harden fine cutting tools of high speed steel. This furnace is scientifically designed and built. It produces a large output of accurate work, and can be depended on where home-made, hit-or-miss methods cannot. Don't guess. Be sure. Use a Tate-Jones Furnace.

Bulletin containing complete information sent upon request. Mention the nature of the work you do and we will send specific information.
